Springer

Welcome to the EANM Congress 2015 in Hamburg

With great pleasure the European Association of Nuclear Medicine welcomes you to its 28th Annual Congress in Hamburg, Germany.

During the EANM Congress you will be able to discuss the state-of-the-art that clinical, translational and fundamental nuclear medicine has to offer in the usual multidisciplinary setting that is so typical for our profession. From all over the world physicians, scientists and technologists will travel to Hamburg for EANM'15 to attend plenary lectures, scientific sessions and the state of the art in nuclear medicine and molecular imaging presented in Continuing Medical Education (CME).

This year's plenary sessions will focus on Clinical Molecular Imaging on Sunday, October 11 (including the Marie Curie Lecture by Prof. Stefano Fanti from Bologna, Italy on the role of nuclear medicine in prostate cancer), and on Therapeutic Nuclear Medicine on Monday, October 12. As part of the M2M - Molecule to Man track, which this year is featured over three days of the Congress, the plenary session on Tuesday, October 13 will focus on Targets and Probes. We are very pleased that Prof. Paul Workman, President and CEO of The Institute of Cancer Research, London, UK will address target discovery and probe identification in oncology, to be followed by lectures of Dr. Matthias Friebe and Prof. Guus van Dongen on probe selection and development for molecular imaging and therapy from the perspective of industry and academia, respectively. Of course the traditional Highlights Lecture on Wednesday, October 14 is scheduled, this year presented by Prof. Andreas Buck and Prof. Clemens Decristoforo.

This year we again feature special tracks. Last year's very successful Biology track has been renamed to the M2M - Molecule to Man track. Thanks to the efforts of the EANM Translational Molecular Imaging, Drug Development and Radiopharmacy Committees, you will find a wealth of events on basic and translational research in molecular imaging and therapy on Monday, Tuesday and Wednesday, including Tuesday's plenary session. As a sequel to "ISTARD", the collaborative efforts of the EANM Dosimetry and Radionuclide Therapy Committees resulted in an annual track now named Dosimetry and Molecular Radiotherapy (Do.MoRe) which will run throughout the Congress.

The Scientific Programme Committee, representing all EANM Committees, received a total of 1.916 abstracts, of which 1.710 were accepted for oral sessions (500 presentations) or poster sessions (1.210 presentations). In the pre-congress and joint symposia, a large number of experts from disciplines outside nuclear medicine together with experts from the EANM Committees will provide new data and will share with you how nuclear medicine contributes to better science and enhanced patient care throughout the areas in which nuclear medicine is utilised.

In collaboration with the European School of Nuclear Medicine, the EANM Committees organised a full track of CME sessions, including the highly appreciated interactive sessions. Education in cross-sectional imaging has been expanded to meet the needs of nuclear medicine physicians for performing state-of-the-art hybrid imaging. The Young EANM organised activities focussed on the career perspective of young professionals in nuclear medicine. Serving the nuclear medicine technologists, the EANM Technologist Committee again designed a full parallel programme of oral and poster sessions as well as Continuing Technologist Education (CTE) sessions and courses.

Organisation of the EANM'15 Congress has been the work of many members of the EANM Committees, strongly supported by the staff of the EANM Executive Office. During the meeting the speakers and presenters will share their data with you. I thank all those who contributed their time and effort into presenting a five-day meeting for you to learn, discuss and enjoy.

On behalf of the EANM Board, the EANM Scientific Programme Committee, the Local Organising Committee and the staff of the EANM Executive Office in Vienna, I welcome you to the EANM Congress 2015 and I hope you will experience a scientific, educational and successful meeting that meets your expectations and offers you a pleasant stay in Hamburg.

Prof. Dr. Wim J.G. Oyen
EANM Congress Chair 2014-2016

Investigation on the number of PET measurements needed for accurate prediction of therapeutic biodistribution in PRRT

D. Hardiansyah[1,2], W. Guo[1], P. Kletting[3], B. Müller[4], F. Mottaghy[4], G. Glatting[1]; [1]Medical Radiation Physics/Radiation Protection, Universitätsmedizin Mannheim, Medical Faculty Mannheim, Heidelberg University, Mannheim, GERMANY, [2]Department of Radiation Oncology, Universitätsmedizin Mannheim, Medical Faculty Mannheim, Heidelberg University, Mannheim, GERMANY, [3]Klinik für Nuklearmedizin, Universität Ulm, Ulm, GERMANY, [4]Klinik für Nuklearmedizin, University Hospital, RWTH Aachen University, Aachen, GERMANY.

Aim: Aim of this study was to investigate the variability of individual time-integrated activity coefficient (TIAC) prediction for different positron emission tomography (PET) measurement protocols in peptide-receptor radionuclide therapy (PRRT).Material and Methods: Assumed true model parameters were derived using "Simulation, Analysis and Modeling II" software by fitting the physiology based pharmacokinetic (PBPK) model parameters to the data of 15 patients (^{111}In-DTPAOC, serum and organ activity data). Predicted model parameters based on the simulation of PET measurements were derived as follows: first, a PET measurement after bolus injection of 150 MBq of ^{68}Ga-DOTATATE was simulated using the assumed true model parameters; second, different PET sampling protocols (PSPs) were implemented to take organ activity data from the simulated time activity curve of ^{68}Ga-DOTATATE. Six PET sampling protocols were investigated: 30 min (PSP1), 60 min (PSP2), 240 min (PSP3), 30 min plus 60 min (PSP4), 30 min and 240 min (PSP5), 60 min and 240 min (PSP6); third step, random noise was added to the simulated organ activity data with fractional standard deviation (FSD) of 10^{-3} using the "PopKinetics" software; fourth, the PBPK model was fitted to these noisy data to derive predicted model parameters. The therapeutic biodistribution was simulated for the model with true parameters and the model with predicted parameters assuming an infusion over 30 min of 3.3 GBq ^{90}Y-DOTATATE. Time integrated-activity coefficients (TIACs) of tumour and kidneys were calculated for both models. The variability between predicted TIACs and true TIACs were compared for tumor and kidneys. Results: Protocols with simulated PET measurement (PSP 1 to 3) showed high values for both kidneys and tumour variabilities. In these 3 protocols PSP 3 sampling at 240 min showed the lowest variability for kidneys (10±7) % and tumour (28±24) %. Variabilities obtained using two time-point PET data (PSP 3 to 6) were much smaller than those of one time-point PET data. The best results were found at PSP6 which were (2±) % for kidneys and (7±1) % for tumour. Conclusion: The PET

measurement protocol at 240 min post injection is important for predicting the therapeutic biodistribution. Protocols with two time-point PET measurements showed higher accuracy than those with one PET measurement. The protocol with PET measurements at 60 min and 240 min post injection is recommended for further investigations.

OP010

The prediction accuracy of therapeutic biodistribution in PET-based treatment planning of PRRT with different Bayesian parameter estimation methods

W. Guo[1], D. Hardiansyah[1,2], A. A. Attarwala[1,2], C. Maaß[1], G. Glatting[1]; [1]Medical Radiation Physics/Radiation Protection, Universitätsmedizin Mannheim, Medical Faculty Mannheim, Heidelberg University, Mannheim, GERMANY, [2]Department of Radiation Oncology, Universitätsmedizin Mannheim, Medical Faculty Mannheim, Heidelberg University, Mannheim, GERMANY.

Aim: The aim of this study was to compare the prediction accuracy of therapeutic biodistributions in PET-based treatment planning of peptide-receptor radionuclide therapy (PRRT) with two Bayesian parameter estimation methods. Materials and Methods: A recently developed physiologically based pharmacokinetic (PBPK) model was fitted to the biokinetic data of patients (SAAM II, The Epsilon Group, Charlottesville, USA) using two different methods: Standard Two-Stage (STS) and Iterative Two-Stage (ITS). The two methods yield assumed true parameters (TPs) and Bayesian parameters. Biokinetic data of 14 patients were obtained after the bolus injection of 152±15 MBq of ^{111}In-DTPAOC from the serum activity and the organ activity taken by a Gammacamera. Based on assumed true parameters PET measurements were simulated after bolus injection of ^{68}Ga-DOTATATE of 150 MBq. Organ activity data from simulated time activity curves were taken at 30 min, 60 min and 240 min post injection. A PET noise model with related coefficient c of 3 and 30 which simulates typical error in PET measurements was included to simulate the organ activity data for used time points. The PBPK model was fitted to the simulated noisy PET data with Bayesian parameters obtained by STS and ITS to derive predicted parameters (PPs). Therapy was simulated for TPs and PPs assuming an infusion of 3.3 GBq of ^{90}Y-DOTATATE over 30 min. Area under the curves (AUCs) of simulated time activity curves in kidneys and tumour were calculated for therapeutic biodistribution using TP (AUC_{TP}) and PP (AUC_{PP}). Variability between AUC_{TP} and AUC_{PP} was calculated and analysed. Result: For noise level of c = 3 using Bayesian parameter from ITS the variabilities were (9 ±7) % for tumour and (2±1) % for kidney, while they were (14 ±9) % for tumour and (2±3) % for kidneys using the Bayesian parameters from STS. The highest variabilities were (18±11) % for tumour and (3±2) % for kidneys for c=30 using Bayesian parameters from STS and it was (12±9) % for tumour and (2±1) % for kidneys using ITS. Within the same coefficient of noise level the variability of AUCs with the ITS method showed lower values for both tumour and kidneys than using the STS method. However, no significant ($p<0.05$, Student's t test) difference was found. Conclusion: The ITS fitting method seems better suited for deriving the Bayesian parameters and predicting the therapy. Further investigation based on a larger population size and with improved sampling schedule is however needed.

OP011

Fractional contribution of extrapolations after 96 h in absorbed dose calculation to kidneys in 450 patients with neuroendocrine tumours receiving ^{177}Lu-DOTATATE therapy

M. Sandstrom, U. Garske-Román, D. Granberg, A. Sundin, M. Lubberink; Nuclear medicine & PET, Uppsala University, SWEDEN.

Aim: As in all therapies using ionizing radiation, a patient-specific optimization of the delivered radiation should be performed in therapy with ^{177}Lu-DOTA-D-Phe1-Tyr3-octreotate (^{177}Lu-DOTATATE). To determine the total time-integrated activity concentration in an organ, extrapolation from the first measurement to time of injection and extrapolations from the last measurement to infinity are needed. It is stated in EANM guidelines that the fractional contribution from the extrapolations should be less than 20% for bone marrow and whole-body dosimetry [1]. The main aim of the present work was to study the fractional contribution after 96 h to the time-integrated activity in kidney in therapy with ^{177}Lu-DOTATATE. Secondary aim was to investigate the influence on the absorbed dose calculation. Materials and Methods: Four hundred fifty patients (219 female and 231 male) with neuroendocrine tumors with high somatostatin receptor expression were included. SPECT/CT over the abdomen were acquired at 24, 96 and 168 h after start of infusion of ^{177}Lu-DOTATATE. In two patients one kidney was excluded due to adjacent tumours. For the kidneys the fractional contribution was calculated for a single therapy cycle of 7.4 GBy from 96 h to infinity. Ratios between absorbed dose calculations performed using only 24 and 96 h measurements AD(24-96) versus absorbed dose calculations performed using 24, 96 and 168 h measurements AD(24-96-168) was performed. Results and discussion: In the right kidney the extrapolated fractional contribution after 96 h

was 29% (Median; Min - Max 12-60) while the absorbed dose ratio was 0.97 (0.67-1.64). The fractional contribution after 96 h was higher than the recommended 20%, not including the time before the first measurement. For the majority of the patients the AD(24-96) estimation gave a value close to the AD(24-96-168) but overestimations of up to 60% and underestimations of up to 30% of the absorbed dose were also seen. No significant differences between left and right kidneys were found. Conclusions: To meet the EANM dosimetry committee recommendation of at most 20% extrapolated fractional contribution in the determination of kidney doses and to get a reliable absorbed dose estimation, it is not sufficient to have the last measurement point at 96 h p.i., and later measurements are needed. 1. Hindorf C, Glatting G, Chiesa C, Linden O, Flux G. EANM Dosimetry Committee guidelines for bone marrow and whole-body dosimetry. OP012

Preliminary results of a Dosimetry-Based peptide receptor radionuclide therapy in patients with advanced neuroendocrine tumors

A. Filice[1], F. Fioroni[2], E. Grassi[2], V. Ferri[2], M. Casali[1], M. Roncali[1], M. Sollini[3], A. Frasoldati[4], A. Versari[1]; [1]Department of Nuclear Medicine IRCCS-Arcispedale Santa Maria Nuova, Reggio Emilia, ITALY, [2]Medical Physics Unit, IRCCS-Arcispedale Santa Maria Nuova, Reggio Emilia, ITALY, [3]IRCCS MultiMedica, Sesto San Giovanni, Reggio Emilia, ITALY, [4]Endocrinology Unit IRCCS-Arcispedale Santa Maria Nuova, Reggio Emilia, ITALY.

Purpose: Peptide Receptor Radionuclide Therapy (PRRT) has an important role in the treatment of advanced neuroendocrine tumors (NETs). Dosimetry allows to personalize this therapy. The aim of this study is to create a strategy of treatment balancing renal protection and tumor treatment, using both ^{177}Lu-DOTATOC and ^{90}Y-DOTATOC to obtain the best ratio. Methods: The PRRT protocol that we are using in our center is a monocenter, rospective, non-randomized, phase II study. It is a dosimetry-based study in which the dosimetric evaluation (kidney, bone marrow, tumor) is performed at the first cycle of ^{177}Lu-DOTATOC. According to these data we calculate the projected adsorbed dose for kidneys, bone marrow and tumor tissues (max 5 lesions). A cohort of 12 patients who underwent more than 2 PRRT administrations and 2 68Ga-DOTATOC PET-CT scans (PET1: baseline and PET2: after the second cycle) were selected. Up to 5 target lesions/patient (volume range 2.3-243 ml) were analysed. Lesions analysed were grouped based on the localisation: liver (28), lymph node (7), and bone (8). The dose to the lesions was calculated at organ level through multiple SPECT-CT scans with the OLINDA/EXM sphere model. Maximum SUV value was evaluated for each lesion and the percentage difference (PD%) between PET1 and PET2 values was calculated. Results: Mean, standard deviation (SD), and range values for PD% were: liver (2.2, 31, -49-75); lymph node (25, 62, -45-117); bone (8, 16, -6-45). Absorbed doses were: liver 41±26 Gy, lymph node 19±29 Gy, bone 13±13 Gy. We found higher correlation between absorbed doses and SUV max at PET1 for all lesions (liver, lymph node, bone), than between absorbed doses and lesions volume. We didn't find a good correlation between absorbed doses and PD%. Conclusions: These preliminary results suggest that a dosimetric evaluation at the first cycle of PRRT allows to obtain a good personalization of the treatment approach. The range of lesion adsorbed doses and PD% values is very broad but probably the second cycle is not adequate to investigate the correlation between tumor response and site of disease because is too early in this clinical setting.

OP013

Pre-treatment intensity of DOTATOC uptake for prediction of response to selective intravascular radionuclide therapy

T. D. Poeppel[1], H. V. Ngo[1], I. Binse[1], H. Lahner[1], N. Unger[1], A. Bellendorf[1], S. Ezziddin[2], A. Bockisch[1], A. Sabet[1]; [1]Universitaetsklinikum Essen, Essen, GERMANY, [2]Universitaetsklinikum des Saarlandes, Homburg, GERMANY.

Aim: DOTATOC PET/CT is known to depict somatostatin receptor expression of neuroendocrine tumour (NET) lesions. Yet, DOTATOC uptake is also related to the perfusion of a lesion. There is a strong connection between the perfusion of a lesion and treatment response in selective intravascular radionuclide therapy (SIRT). Yet, it is unclear if DOTATOC uptake may serve as a parameter to predict treatment response in SIRT. This study assesses the value of baseline line DOTATOC PET in predicting the response to SIRT with Y-90-microspheres in patients with hepatic metastatic NET. Methods: 25 patients with hepatic metastatic gastroenteropancreatic (GEP) NET who were treated with SIRT were retrospectively analysed. Ga-68-DOTATOC-PET/CT was performed at baseline and three months after the treatment. The maximum standardised

uptake value (SUVmax) was determined as a measure of DOTATOC uptake. In each patient a maximum of three clearly delineated tumour lesions was selected as target. SUVmax and tumour-to-spleen ratios (SUVmaxT/s) of target tumour lesions were calculated. Response of each tumour lesion was evaluated according to the relative change in SUVmaxT/s (%Δ SUVmaxT/s). The association of baseline SUV parameters and functional response was tested using Spearman's rank correlation analysis. Results: 69 lesions were included into the analysis. Mean tumour and splenic SUVmax at baseline were 19.9 ±1.7 and 23.4 ±1.7, respectively. 50 lesions showed a reduction in SUVmax three months after SIRT. Mean post-SIRT SUVmax was 10.8±1.7. Relative change in SUVmaxT/s was 26.7±12.8 %. Baseline SUVmax showed a moderate (r=0.132) and SUVmaxT/s a slightly better correlation with lesion-based response (r=0.441). Conclusions: Pre-treatment intensity of DOTATOC uptake in terms of SUV parameters is only moderately related to lesion-based functional response to SIRT in GEP NET patients.

OP014

An image based method for bone marrow dosimetry in 177Lu-DOTATATE therapy

J. Svensson[1], J. Söderström[2], T. Magnander[2], E. Wikberg[2], B. Wängberg[3], P. Bernhardt[2]; [1]Department of Oncology, The Sahlgrenska Academy, Sahlgrenska University Hospital, Göteborg, SWEDEN, [2]Department of Radiation Physics, The Sahlgrenska Academy, Sahlgrenska University Hospital, Göteborg, SWEDEN, [3]Department of Surgery, The Sahlgrenska Academy, Sahlgrenska University Hospital, Göteborg, SWEDEN.

Aim: Treatment with 177Lu-DOTATATE for advanced neuroendocrine tumours expressing somatostatin receptors has proven efficient and safe. Organs at risk are mainly the kidneys and the bone marrow. Though well tolerated in general, bone marrow toxicity might become dose limiting. The aim of this study was to evaluate an image based method to estimate the absorbed dose to the bone marrow during 177Lu-DOTATATE treatment. Materials and methods: 51 patients with advanced neuroendocrine tumours were treated with 177Lu-DOTATATE on 1-6 occasions. The patients were evaluated according to the mean absorbed dose to the bone marrow using the 4 planar images collected at 2, 24, 48 and 168 hour after injection. By using a segmentation tool in the in-house made software RONSO, the high uptake area in the images was separated from the low uptake area. The high uptake area consisted of the tissue related activity in tumours and organs, and the low uptake area contained the blood related activity in the images. Absorbed dose to the bone marrow was calculated as sum of; the self-dose from charges particles in the bone marrow, the cross-dose from the tissue related area (solely γ-radiation contribution) and the cross-dose from the blood related area. Results: The median of the mean absorbed dose to the bone marrow was 0.17 Gy (range 0.08 - 0.49 Gy) for the first therapy cycle; where an average amount of 7.5 GBq (range 4.2 - 8.3 GBq) 177Lu-DOTATATE was administered to the patients. For all the treatment cycles (in average 3 occasions) the median of the mean absorbed dose was 0.51 Gy (range 0.16 - 1.35 Gy). The self-dose made the largest contribution to the mean absorbed dose to the bone marrow. Conclusion: The image based method developed in this work might be useful for bone marrow dosimetry. The mean absorbed doses varied considerably between patients which illustrates the need for individual dosimetry, especially when the total amount of 177Lu-DOTATATE in on-going studies tend to increase, and also when other treatment options make it necessary to preserve bone marrow function. The method requires to be validated for a more patient specific purpose, which can be done by blood dosimetry from blood sampling.

OP015

Prediction accuracy of therapeutic biodistribution in peptide receptor radionuclide therapy: Role of patient-based treatment planning

D. Hardiansyah[1,2], C. Maaß[1], A. Attarwala[1,2], P. Kletting[3], B. Müller[4], F. Mottaghy[4], G. Glatting[1]; [1]Medical Radiation Physics/Radiation Protection, Universitätsmedizin Mannheim, Medical Faculty Mannheim, Heidelberg University, Mannheim, GERMANY, [2]Department of Radiation Oncology, Universitätsmedizin Mannheim, Medical Faculty Mannheim, Heidelberg University, Mannheim, GERMANY, [3]Klinik für Nuklearmedizin, Universität Ulm, Ulm, GERMANY, [4]Klinik für Nuklearmedizin, University Hospital, RWTH Aachen University, Aachen, GERMANY.

Aim: An accurate treatment planning is needed in peptide-receptor radionuclide therapy (PRRT) for ensuring the optimal tumor irradiation while diminishing the toxicity for the kidneys. The aim of this study was therefore to show the prediction accuracy of the therapeutic biodistribution in peptide receptor radionuclide therapy (PRRT) for different degrees of individualization when using physiologically based pharmacokinetic modelling (PBPK).Material and Methods: The parameter of a recent PBPK model of PRRT were fitted to the biokinetic data of 15 patients with metastasized neuroendocrine tumors (NETs): serum and

planar gamma camera data after the injection of ^{111}In-DTPAOC to derive the assumed true model parameters. Four mathematical phantom patients (MPP) were defined with increasing amount of patient-specific information: MPP_{true} is the PBPK model with 15 sets of all assumed true model parameters; MPP_{mean} is the PBPK model with all model parameters fixed to the mean values of the 15 patients; $MPP_{specific}$ uses additional individual patient data: physical parameters (body weight, body surface area, age, gender), hematocrit, volume of the tumor, glomerular filtration rate and flow to the tumor; MPP_{PET} is $MPP_{specific}$ with one simulated positron emission tomography (PET) data set at t=60 min after injection of ^{68}GA-DOTATATE to fit the model parameters. Therapy was simulated as an infusion of 3.3 GBq of ^{90}Y-DOTATATE over 30 min for all MPPs. Area under the curve (AUC) of time activity curve in tumor and kidneys were calculated for total simulation duration of 14 d. The relative differences (RD) of AUCs of MPP_{mean}, $MPP_{specific}$ and MPP_{PET} to MPP_{true} were analyzed. Results: RDs of MPP_{mean} were RD_{tumor} = (625±1266) % and $RD_{kidneys}$ = (11±38) %, demonstrating that patient individual data are needed for treatment planning. Inclusion of patient individual data in $MPP_{specific}$ lead to significantly lower RD in the tumor: RD_{tumor} = (-2±27) % and $RD_{kidneys}$ = (16±43) %. RD in MPP_{PET} showed a major improvement for the kidneys due to the inclusion of simulated PET data: RD_{tumor} = (-2±22) % and $RD_{kidneys}$ = (-0.1±0.5) %. Summary: Individual biokinetics are needed to predict the biodistribution in PRRT using theses somatostation analogs. Additional use of a single PET measurement together with the PBPK model significantly improved the prediction.

OP016

The variability of predicted area under the curves for different degrees of noise in PET measurements for treatment planning in peptide-receptor radionuclide therapy

D. Hardiansyah[1,2], W. Guo[1], P. Kletting[3], B. Müller[4], F. Mottaghy[4], G. Glatting[1]; [1]Medical Radiation Physics/Radiation Protection, Universitätsmedizin Mannheim, Medical Faculty Mannheim, Heidelberg University, Mannheim, GERMANY, [2]Department of Radiation Oncology, Universitätsmedizin Mannheim, Medical Faculty Mannheim, Heidelberg University, Mannheim, GERMANY, [3]Klinik für Nuklearmedizin, Universität Ulm, Ulm, GERMANY, [4]Klinik für Nuklearmedizin, University Hospital, RWTH Aachen University, Aachen, GERMANY.

Aim: Accuracy of treatment planning in peptide-receptor radionuclide therapy (PRRT) depends on the variability of the individually predicted biodistribution. The aim of this study was to investigate the variability of the area under the curves (AUCs) for different degrees of noise in simulated positron emission tomography (PET) measurements for PRRT.Material and Methods: A physiologically based pharmacokinetic (PBPK) model of PRRT was used in this study. Assumed true model parameters for 15 patients were derived using "Simulation, Analysis and Modeling II" software by fitting the PBPK model parameters to their biokinetic data (^{111}In-DTPAOC, serum and organ activity data). Predicted model parameters based on the PET simulation were derived as follows: first, a PET measurement after bolus injection of 150 MBq of ^{68}Ga-DOTATATE was simulated using the assumed true model parameters; second, the organ activity data of kidneys, tumour, spleen and liver at 60 min and 240 min post injection were taken; third, random noise was added to the simulated organ activity data with fractional standard deviations (FSD) of 10^{-1}, 10^{-2}, 10^{-3}, and 10^{-4} using the "PopKinetics" software; fourth, the PBPK model was fitted to these noisy data to derive predicted model parameters for the patients. Two mathematical patient phantoms (MPPs) were built: true MPP (PBPK model with assumed true model parameters) and predicted MPP (PBPK model with predicted model parameters). Therapeutic biodistribution was simulated for true and predicted MPPs assuming an infusion over 30 min of 3.3 GBq ^{90}Y-DOTATATE. AUCs of tumour and kidneys were calculated for both MPPs. The variability V between predicted AUCs and true AUCs were calculated for tumour and kidneys. Results: The variabilities for FSD = 10^{-1} and 10^{-2} showed low accuracy for the prediction of the therapeutic biodistribution: FSD = 10^{-1} yielded V_{tumor} = (27±23) % and V_{kidney} = (13±5) %; FSD = 10^{-2} yielded V_{tumor} = (23±10) %, V_{kidney} = (7±3) %. FSD 10^{-3} and FSD 10^{-4} showed acceptable variabilities for the prediction (V_{tumor} = (8±2) %, V_{kidney} = (2±1) % and V_{tumor} = (1±1) %, V_{kidney} = (0.3±0.3) % for FSD = 10^{-3} and 10^{-4}, respectively. Conclusion: Organ activity measured from two time points by PET could possibly be used to reliably predict the individual therapeutic biodistribution. Typical PET measurements have noise equal or lower than FSD=10^{-3} and thus could possibly lead to an acceptable prediction of therapeutic biodistribution.

First-in-man experience of CXCR4-directed endoradiotherapy with ^{177}Lu- and ^{90}Y-labelled pentixather in heavily pretreated multiple myeloma with extensive intra- and extramedullary disease

K. Herrmann[1], M. Schottelius[2], C. Lapa[1], A. Poschenrieder[2], H. Hänscheid[1], U. Keller[2], A. Schirbel[1], S. Kropf[3], A. K. Buck[1], S. Knop[1], H. Einsele[1], H. Wester[2]; [1]Universitätsklinikum Würzburg, Würzburg, GERMANY, [2]Technische Universität München, München, GERMANY, [3]Scintomics GmbH, Fürstenfeldbruck, GERMANY.

Aim: The chemokine receptor CXCR4 is a key factor for tumor growth and metastasis in several types of human cancer. Based on our promising experiences with a radio-labelled CXCR4 ligand ([68Ga]pentixafor) for diagnostic receptor targeting, [177Lu]- and [90Y]pentixather were recently developed as endoradiotherapeutic vectors. Here, we summarize the first-in-man experience with CXCR4-directed therapy with these radiolabelled receptor ligands. Materials and Methods: Three patients with intra- and extensive extramedullary manifestations of multiple myeloma were included. All had exhausted all available treatment options including stem cell transplant (SCT). CXCR4-target expression was demonstrated by baseline [68Ga]pentixafor-PET. Each treatment was approved by the clinical ethics committee. Pre-therapeutic [177Lu]pentixather dosimetry was performed prior to treatment with 15.2 and 23.5 GBq [177Lu]pentixather, and 6.3 GBq [90Y]pentixather, respectively. Subsequently, patients underwent additional chemotherapy and autologous SCT for bone marrow rescue. Early treatment response was monitored by conventional criteria and [18F]FDG-PET/CT. Results: Pentixather-radionuclide therapy was well tolerated in all 3 patients. Two patients underwent response assessment with [18F]FDG-PET/CT showing significant therapeutic effect with one partial and one complete metabolic response. Conclusion: In combination with cytotoxic chemotherapy and autologous SCT, CXCR4-targeted radiotherapy with pentixather appears to be a promising novel treatment option for patients with advanced multiple myeloma, especially in patients with extramedullary manifestations.

OP036
Radionuclide treatment with 64Cu-Cl2 in patients with progressive malignant gliomass

E. Capasso, Jr.[1], M. C. Valentini[2], S. Mirzaei[3], P. Knoll[3], C. Meleddu[1]; [1]U.O.C. Nuclear Medicine, Cagliari, ITALY, [2]S.C. Neuroradiology, C.T.O., Turin, ITALY, [3]Department of Nuclear Medicine with PET-Center, Wilhelminenspital, Vienna, AUSTRIA.

Background: Gliomas are the most common type of brain tumor, of which malignant astrocytomas (MA), also defined as glioblastoma multiforme (GBM) and anaplastic astrocytoma (AA) have a poor survival rate. The standard care is based on cyto-reductive surgery followed by radiotherapy and adjuvant chemotherapy (CHT). Several trials have been performed with i.e. combination of temozolomide, thalidomide with antiangiogenetic drugs, but the impact on survival remains limited. Further, many types of cancers typically show high levels of

copper, including gliomas. Beaucase of its ß- emission the copper isotope 64Cu has been discussed for therapeutic applications. AIM: The aim of this case study was to evaluate the possible impact of treatment with 64Cu-Cl2 in patients with progressive GBM and AA despite previous standard treatment. MATERIALS AND METHODS: A 51y female patient affected by GBM with primary localization in left thalamus with progressive disease (PD) after surgery and radiochemetherapy was enrolled. She received twice intravenously a dose of 3300 and 2590 MBq of 64CuCl2 in alternating days. The treatment was well tolerated, without clinical side effects. The patient underwent to a PET/CT scan, from vertex to thorax, 1 hour after the tracer administration. RESULTS: The 64CuCl2 PET scan showed a high uptake in left thalamic and frontal lesions, in correlation to the known morphologic target lesions. One month later the patient underwent to a control MRI which showed remarkable volume reduction of the lesions with disappearance of the previously peritumoral edema and readjustement of the brain midline structure. CONCLUSIONS: Radinuclide treatment with 64CuCl2 is very well tolerated and could be of potential benefit in malignant glioma patients with PD despite standard treatment.

OP037

Clinical Feasibility and Effectiveness of Intraperitoneal Radionuclide Therapy with Lu-177 3BP-227 in Metastatic Adenocarcinoma of Pancreas

A. Singh[1], H. Kulkarni[1], C. Schuchardt[1], S. Wiessalla[1], M. Sayeg[1], I. Klette[1], F. Osterkamp[2], U. Reineke[2], C. Smerling[2], R. P. Baum[1]; [1]Zentralklinik Bad Berka, THERANOSTICS Center for Molecular Radiotherapy and Molecular Imaging (PET/CT), Bad Berka, GERMANY, [2]3B Pharmaceuticals GmbH, Berlin, GERMANY.

Aim: Metastatic pancreatic adenocarcinoma (mPaCa) has a very poor prognosis. Following our experience on dosimetry and intravenous (i.v.) radiopeptide therapy with Lu-177 3BP-227 (a neurotensin antagonist targeting NTR-1), we report the feasibility and effectiveness of serial intraperitoneal administrations of Lu-177 3BP-227 for the treatment of mPaCa.Materials and Methods:A 59-year old female with inoperable mPaCa (vascular infiltration, lymph node, liver, peritoneal metastases) and massive ascites was referred with progressive disease after 7 cycles of chemotherapy for radiopeptide therapy. Following initial feasibility and dosimetry using 1400 MBq of i.v. Lu-177 3BP-227, the patient received 6400, 7500, and 5300 MBq Lu-177 3BP-227 over a period of six months. Dosimetry (MIRD) was performed using OLINDA/EXM software. Feasibility was assessed by dosimetry, patient tolerance, side-effects, and toxicity profile (hematological, renal, liver) based on serial determination of laboratory tests and renal scintigraphy. Effectiveness was assessed by monitoring clinical outcome, tumor markers, and by imaging (PET/CT) pre- and post-therapy.Results:Clinical feasibility was confirmed by tolerance of therapy without any significant side effects. Liver parameters remained within normal limits during therapy. Serial whole-body scintigraphy and SPECT/CT demonstrated excellent tracer uptake in the primary tumor and in the widespread metastases. On dosimetry, whole-body uptake showed a bi-exponential decline, the tumor uptake followed an exponential decline, and the kidneys showed an exponential clearance with more prolonged kinetics compared to i.v. application. Mild and reversible hematotoxicity (Hb 5.9 mmol/L) was observed after the second dose (anemia existed before therapy). No renal toxicity was observed (despite there was only a single functioning kidney).Therapeutic effectiveness was confirmed by clinical assessment (significant improvement in quality of life and functional status), and severe reduction in ascites formation (drainage from twice daily to once every 3 days). Partial Remission (PR) was achieved according to RECIST (regression in size of the primary tumor and the hepatic metastases on MRI and CT) and by PERCIST (reduction of uptake in primary tumor and metastatic lesions on F-18 FDG PET/CT). Finally, a persistent fall of the tumor marker CA 19-9 (from 1423 to 192 U/ml) occurred. The patient is still alive 8 months after start of PRLT. Conclusion: Intraperitoneal peptide radioligand therapy using Lu-177 3BP-227 was clinically feasible and effective for the management of metastatic pancreatic adenocarcinoma. The excellent results obtained in this patient warrant the need of further studies and possibly earlier application of Lu-177 3BP-227 for the therapy of peritoneal carcinomatosis and associated ascites.

OP038

Nanovectorized radiotherapy by convection-enhanced delivery (CED), a promising strategy that demonstrates high efficacy in a murine model of human endometrial adenocarcinoma.

A. Genin[1,2,3], C. Lefebvre-Lacoeuille[1,3,2], J. Rousseau[4,5], N. Chouin[4,5], P. Fosse[6], D. Dabli[6], F. Bouchet[6], N. Lepareur[7], P. Descamps[1,3], F. Hindré[1,8,2], O. F. Couturier[1,6,2], **F. Lacoeuille**[1,2,6]; [1]LUNAM Université, Angers, FRANCE, [2]Inserm UMRS_1066 MINT, Angers, FRANCE, [3]Department of Obstetrics and Gynaecology, CHU Angers, Angers, FRANCE, [4]LUNAM Université, Nantes, FRANCE, [5]AMaROC, ONIRIS, Nantes, FRANCE, [6]Nuclear Medicine Department, CHU Angers, Angers, FRANCE, [7]Department of Nuclear Medicine, Centre Eugène Marquis, Rennes, FRANCE, [8]PRIMEX Plateforme de Radiobiologie et d'Imagerie Expérimentale, Angers, FRANCE.

Aim: To evaluate the biodistribution, the toxicity, the dosimetry and the antitumor efficacy of intra-tumoral injection of rhenium-188 loaded nanoparticles (LNC-188Re-SSS) by

CED. Materials and methods: Ishikawa endometrial carcinoma cell lines were implanted subcutaneously in nude mice (n=70). For biodistribution and efficacy studies CED procedure was realized at D28 after tumour implantation. CED was performed using an osmotic pump (0.5μL/min for 20 minutes) after immobilisation of anaesthetized mice on a stereotactic frame. For biodistribution studies, animals (n=30) were injected by CED either with 3MBq of 188ReO4- (n=15) or LNC-188Re-SSS (n=15) and sacrificed at 1h (n=10), 24h (n=10) or 72h (n=10). For efficacy studies, control group mice were injected by CED with saline (n=8) or blank LNC (n=8) and treated group mice were injected with escalating dose of LNC-188Re-SSS: 3MBq (n=8), 6 MBq (n=8) or 12 MBq (n=8). Efficacy on tumour growth was assessed by clinical palpation and μMRI. The time for the tumour volume doubling was chosen as endpoint, leading to the euthanasia of the animal. The physical dose deposited in the tumour for each treated animal was estimated by Monte Carlo simulation (Geant4) using measured biodistribution and μMRI tumour volumes,. Haematological toxicity in mice was evaluated using blood sampling of 50μL (retro-orbital sinus) at D2, D7, D14 and D21 after treatment with saline (n=4) and after treatment with LNC-188Re-SSS, 3MBq (n=4), 6MBq (n=4) or 12 MBq (n=4). Results: Nanovectorization of 188Re combined with CED allowed the confinement of more than 30 % of ID in the tumour limiting therefore urinary excretion of 188Re since 0,1% versus 81,9% of ID were excreted in urine 24h after CED of LNC-188Re-SSS and 188ReO4- respectively (p=0.016). Nanovectorized radiotherapy has drastically increased the median survival time compared with control group. Animals whose tumor received a dose higher than 69 Gy (69-340 Gy) showed an ISTmedian of + 933%, whereas animals whose tumor received a dose lower than 69 Gy (21-67Gy) showed an ISTmedian of + 391%. Complete response with eradication of the tumor was observed in 4/12 (33.3%) animals of the former group. Depletion of platelets was observed following LNC-188Re-SSS injection with a time to nadir between D14-D21 whereas transient lymphocyte depletion was only observed at D7 for the highest administered activities (12MBq). Conclusion: CED of LNC-188Re-SSS demonstrates interesting biodistribution properties and high efficacy in a model of human endometrial carcinoma.

OP039

Tumour-Absorbed Dose for Patients in a Phase I study undergoing antibody-radionuclide-conjugate (ARC) therapy with ^{177}Lu-DOTA-HH1

C. Stokke[1], A. Løndalen[2], J. Blakkisrud[1], J. Dahle[3], T. Bach-Gansmo[2], J. Holtedahl[1], A. Martinsen[1], B. Bolstad[3], H. Holte[4], A. Kolstad[4]; [1]The Intervention Centre, Oslo University Hospital, Oslo, NORWAY, [2]Department of Radiology and Nuclear Medicine, Oslo University Hospital, Oslo, NORWAY, [3]Nordic Nanovector ASA, Oslo, NORWAY, [4]Department of Oncology, Radiumhospitalet, Oslo University Hospital, Oslo, NORWAY.

Aim: ^{177}Lu-DOTA-HH1 (Betalutin™) is a novel anti-CD37 antibody-radionuclide-conjugate (ARC) currently under investigation. Betalutin™ is developed by Nordic Nanovector ASA and consists of lutetium-177 which is chelated to the DOTA-conjugated antibody HH1. Oslo University Hospital is participating in a phase I/II study where Non-Hodgkin Lymphoma patients are treated with ^{177}Lu-DOTA-HH1. In the current work, we estimate tumour-absorbed doses and aim to investigate dose-response relationships at the lesion level. Material and methods: Patients with relapsed CD37+ indolent B-cell NHL were eligible for inclusion in the 3x3 dose escalation study. Three dose levels have been tested (10 MBq/kg, 15 MBq/kg, 20 MBq/kg). Eleven patients were assessed for distribution of radioactivity by SPECT/CT at the time-points 96 and 168 hours post administration, of whom 4 also underwent planar whole-body (WB) imaging at additional time points. Clinical response assessment included 18F-FDG PET/CT. PET/CT scans were performed at baseline and at 3 months and 6 months follow-up. In this work, response was assessed by the change in SUV_{max} value for each individual lesion. For 2 patients at each dose level, i.e. a total of 6 patients, we have calculated mean tumour-absorbed dose for 2 or 3 separate lesions. The SPECT/CT images were analyzed, and tumour uptake and volume at the different time points determined. Cumulative activities were calculated from mono-exponential fits, as verified by co-registered conjugate view WB images when available. Results: The mean overall tumour-absorbed dose was 2,13 mGy/MBq (range 0,42 - 4,77 mGy/MBq). For patients in the 10 MBq/kg group, the 15 MBq/kg group (MTD) and the 20 MBq/kg group the median dose was 138 cGy, 297 cGy and 310 cGy, respectively. Interpatient and, to some degree, also intrapatient variances were observed. Dose-rate maps at the voxel level and dose-volume histograms for each tumour were also investigated. Only 3 of the 14 tumours studied showed a less than complete SUV_{max} response at 3 months, thus establishing meaningful correlations between tumour-absorbed dose and response was difficult. However, all 3 lesions with an incomplete response received a dose below the overall mean dose of 286 cGy. This suggested dose-response trend requires investigation of more patients. Conclusion: Tumour-absorbed doses for patients undergoing antibody-radionuclide-conjugate (ARC)

therapy with ^{177}Lu-DOTA-HH1 were determined. Although preliminary results are too limited to establish valid correlations, lesions with an incomplete response received a dose below the overall mean dose. Further evaluation of dose-response relationships will require a larger data material.

Preliminary Dosimetry Results from a Phase II Study Evaluating the Efficacy and Safety of Ultratrace® Iobenguane I 131 in Patients with Relapsed/Refractory Malignant Pheochromocytoma/Paraganglioma

D. A. Pryma[1], C. Jimenez[2], B. Chin[3], J. R. Olsen[4], M. H. Pampaloni[5], L. B. Solnes[6], J. Stubbs[7], T. Armor[8], J. D. Jensen[8], V. Wong[8]; [1]Hospital of the University of Pennsylvania, Philadelphia, PA, UNITED STATES, [2]University of Texas M.D. Anderson Cancer Center, Houston, TX, UNITED STATES, [3]Duke University Medical Center, Durham, NC, UNITED STATES, [4]Washington University School of Medicine, St. Louis, MO, UNITED STATES, [5]University of California, San Francisco, San Francisco, CA, UNITED STATES, [6]Johns Hopkins University, Baltimore, MD, UNITED STATES, [7]Radiation Dosimetry Systems, Inc., Milton, GA, UNITED STATES, [8]Progenics Pharmaceuticals, Inc, Tarrytown, NY, UNITED STATES.

Aim: Radioiodinated meta-iodobenzylguanidine (MIBG) is used for diagnosis and treatment of neuroendocrine tumors, such as pheochromocytomas and paragangliomas (pheo/para). Azedra™ (Ultratrace®iobenguane I131) is a high specific activity form of MIBG developed from a solid phase radiolabeling technology that dramatically reduces cold iobenguane carrier in the final product. Clinical studies with Azedra suggest this may result in reduced toxicity, increased tumor uptake, and anti-tumor activity. The aim of this study is to evaluate the efficacy and safety of two therapeutic doses of Azedra up to 18.5 GBq each (≤296 MBq/kg) given 3 months apart in patients with iobenguane-avid metastatic and/or recurrent pheo/para. Patient-specific dosimetry was employed for treatment planning to confirm the protocol-specified administered activity did not exceed pre-specified absorbed dose levels. Methods: The absorbed radiation dose was estimated after a single IV administration of 111-222 MBq of Azedra. Serial anterior/posterior scintigraphic images were obtained over 3-6 days. Count data was extracted from the whole body scans and CT-based volumes were used to estimate radiation absorbed dose to normal organs and tissues per the MIRD schema. Radiation dose estimates for a planned cumulative therapeutic administration of 37 GBq were performed using OLINDA/EXM software (version 1.1) and reduced when necessary to limit radiation dose under pre-specified limits for the kidneys (<23 Gy), liver (<30 Gy) and lungs (<17.5 Gy). Results: Results are available for 44 patients who underwent dosimetric evaluation. Of these, 41 (93.2 %) demonstrated tumor avidity and 38 (86.4%) were eligible to receive up to 37 GBq based on dosimetry while 6 (13.6%) were eligible with dose reduction. 34 (77.3%) patients received two therapeutic administrations ranging from 32-38 GBq. Mean radiation doses (±SD) were: kidneys, 12±5.1 Gy; liver, 14±4.2 Gy; lungs, 10±3.4 Gy. Mean dose to non-source organs ranged from 2-6 Gy. Mean total body radiation dose was 3.7±0.9 Gy (range 2.4-7.3 Gy). Azedra was generally well tolerated with gastrointestinal and hematologic toxicity most frequently reported. Conclusion: This prospective treatment planning paradigm for high dose therapy is an important safety check-point to estimate potential risks to tissue distribution in critical organs such as kidneys, liver and lungs. Patient-specific treatment planning provides a means of optimizing each patient's therapeutic administration (in this case, activity reduction), regardless of the uniqueness of an individual's specific biodistribution or biokinetics/clearance patterns.

OP041

Lu-177-Trastuzumab as a potential radiopharmaceutical for targeted radionuclide therapy of HER2/neu expressing metastatic breast cancer patients: feasibility study

J. Shukla, P. Bhusari, R. Vatsa, M. Parmar, G. Singh, B. R. Mittal; Post Graduate Institute of Medical Education & Research, Chandigarh, INDIA.

Introduction:Her2/neu expressing breast cancers are the most aggressive type of breast cancers. Trastuzumab is a humanized monoclonal antibody approved by FDA for the treatment of Her2 breast cancer. Radiolabeled antibodies have emerged as promising vehicles for targeted radio-immuno therapy of recurrent and metastatic disease. The aim of the study is to evaluate the feasibility of Lu-177-Trastuzumab for the treatment of Her2/neu expressing metastatic breast cancer. Methods:DOTA-Trastuzumab conjugates were developed using different molar excess of DOTA (5 to 40). The conjugates were purified using gel filtration chromatography. Characterization of the conjugates was done using SDS-PAGE and MALDI/TOF mass spectrometry. Radiolabeling of the conjugated Trastuzumab (0.5-3 mg) (dissolved in acetate buffer;pH=5) was done using Lu-177 chloride(750-850MBq) at 42oC for 2 hours. Post labeling purification of Lu-177-Trastuzumab from free Lu-177 was done

using gel filtration chromatography. The quality control of the purified Lu-177-Trastuzumab was done by radio-ITLC. Sterility and Endotoxin testing was performed. In vitro stability of the Lu-177-Trastuzumab was assessed up to 20 hours post labelling.The ethical clearance was obtained from the Institute's ethics committee. The patients were selected on the basis of [F-18] FDG scan. Immunohistochemistry (IHC) proven Her2 positive (n=3) and Her2 negative (n=3) were enrolled after getting informed written consent. Thewhole-body and SPECT/CT images were acquired at day 1 and day 7/8 post intravenous injection of 185-370MBq of Lu-177-Trastuzumab. The uptake of the radiopharmaceutical in the lesions was correlated with IHC and [F-18]FDG reports. Results:Conjugated trastuzumab with 2.5-8 molecules of DOTA per molecule of antibody was used for clinical grade preparation of Lu-177-Trastuzumab. The conjugated antibody showed two distinct bands of heavy and light chains on SDS-PAGE gel electrophoresis. No peak except corresponding to conjugated antibody was observed in MALDI mass spectra indicated the presence of intact antibody. Radiolabeling yield obtained was 70-91%. The product was stability upto 12 hours post preparation in vitro. The preparations were sterile and endotoxin content was <100 EU/V. The physiological tracer uptake was visible in heart, liver,spleen and nasopharynx. The blood pool activity was very high at 2 hr and was decreased after 7 days.Uptake of Lu-177-Trastuzumab was observed in all Her2 positive breast cancer and its metastatic lesions. No uptake of Lu-177-Trastuzumab was noted in any of the Her2 negative patients on IHC. Conclusion: Lu-177-Trastuzumab SPECT/CT imaging indicated that the radiopharmaceutical may hold great potential for radioimmunotherapy of Her2 overexpressing metastatic breast cancer.

Multiparametric characterization of early tumour response using PET/MR in patients with lung cancer using a voxelwise analysis.

A. M. E. Engberg, A. E. Hansen, S. W. Langer, H. H. Johannesen, N. H. Langer, M. Nørgaard, J. Löfgren, S. H. Keller, L. Højgaard, A. Kjær, B. M. Fischer; Rigshospitalet, Copenhagen, DENMARK.

Aim: In this study we explore if multiparametric imaging with simultaneous FDG-PET and Diffusion Weighted (DW) MRI can improve our understanding of tumour response and flare during chemotherapy and reveal patterns enabling us to early and accurately predict therapy response. Material: Eight patients were recruited from an ongoing, prospective study including patients with histologically or cytologically confirmed lung cancer referred for standard chemotherapy with carboplatin and vinorelbine. The patients underwent simultaneous FDG-PET/MRI (Siemens mMR) prior to (day 0), during (day 2, 7 and/or 12), and after (day 21) the first or second cycle of chemotherapy. Four patients completed 5 PET/MR scans and 4 patients 4 PET/MR scans. Methods: PET/MR was performed one hour after injection of 18F-FDG over 2 bed positions covering thorax. MRI included VIBE-DIXON (for attenuation correction), T1, T2, and DWI (b-values 0, 150, and 1,000). An experienced radiologist and nuclear medicine physician defined tumour volumes on all scans and the following parameters were extracted: SUVmax and SUVmean (maximum and mean standardized uptake value), and ADCmin and ADCmean (minimum and mean apparent diffusion coefficients). A spatial analysis was performed identifying the centre of mass (CM) for the PET and ADC tumour volumes. A multivariate Gaussian Mixture Model (GMM) was applied on the joint ADC and PET data using the Expectation-Maximization algorithm and limiting the number of clusters to 5. Results: All scans were of an acceptable image quality and the CM analysis suggests no significant offset between PET and ADC tumour volumes. Regarding primary tumour two patterns of FDG-uptake were identified: A) Responding pattern, where SUV drops immediately after the first administration of chemotherapy (day 2) and remains largely unchanged on the following scans. B) Non-responding pattern: SUV is unchanged during and after chemotherapy. Regarding ADC values the results are less clear. However, both responding and non-responding patients showed a trend towards an initial decrease after the first dose of chemotherapy followed by an increase. The voxelwise analysis of the joint ADC and PET data indicated a pattern of decreased tumour heterogeneity and identified clusters with apparent anatomical features. Conclusion: Multiparametric imaging with simultaneous FDG-PET and DW-MRI in lung cancer patients is feasible. These preliminary data indicates that it is possible to identify a responding pattern by voxelwise GMM analysis already 24 hours after chemotherapy; potentially enabling a rapid shift to a more efficient therapy in non-responding patients.

OP043

Yttrium-90 PET/MRI is superior to Bremsstrahlungs-SPECT/CT in treatment verification after selective internal radiotherapy - initial results

A. P. Bellendorf[1], B. Gomez[1], J. Schelhorn[2], A. Sabet[1], S. P. Müller[1], H. V. Ngo[1], A. Bockisch[1], T. D. Poeppel[1]; [1]University Hospital Essen, Department of Nuclear Medicine, Essen, GERMANY, [2]University Hospital Essen, Germany, Institute for Diagnostic and Interventional Radiology and Neuroradiology, Essen, GERMANY.

Aim: Bremsstrahlung-(BS) SPECT/CT is currently the preferred imaging modality for assessment of microsphere distribution after selective internal radiotherapy (SIRT). Yet, bremsstrahlung imaging is limited in spatial resolution. With a low decay probability of approx. 1:30 million, positron emission is observed in Y-90 decay which allows assessment of treatment microsphere distribution by positron emission tomography (PET). This study aims to evaluate Y-90 PET/MR for treatment verification after SIRT in comparison with BS-SPECT/CT and pre-treatment Tc-99m HSA-Microspheres SPECT/CT. METHODS: 16 patients with primary and secondary hepatic malignancies underwent pre-treatment Tc-99m HSA-Microspheres SPECT/CT (within 6 weeks before SIRT) and post-SIRT BS-SPECT/CT (both Siemens Symbia T2, acquisition time[AT] 35 min.) as well as Y-90 PET/MRI (Siemens mMR, AT 20min) within 48 hours after SIRT. 3 readers with experience in hybrid imaging and MRI reviewed all datasets. A total of 247 lesions was analysed with regard to the following criteria: 1) number and lesion-to-liver contrast (3-point ordinal scale (OS):1=low-3=good) of focal intrahepatic nuclide depositions including morphological correlation(4-p. OS: 1=no corr.- 4=excellent corr.). 2) Delineation of extrahepatic depositions and quality of anatomical localisation (1=no local.-3=good corr.). 3) Overall image quality (1=non-diagn.-4=good). 4) Correlation with pre-SIRT Tc-99m HSA-SPECT/CT. RESULTS: 1)Y-90 PET/MRI showed more focal deposition than BS-SPECT (82 vs. 74, mean lesions per patient 5,3 vs. 4,6) with higher lesion-to-liver contrast (median contrast 3 vs. 2, p=0.003). 2) More extrahepatic depositions were found in Y-90 PET/MRI with better mean localisation quality (6 vs. 1 lesions, mean quality 1 vs. 3). 3) Overall image quality (IQ) and quality of co-registration (CR) showed no significant difference between PET/MRI and BS-SPECT/CT (mean IQ: 3 vs. 3, CR: 3,5 vs. 4). 4) pre-SIRT HSA-SPECT/CT (5.9 lesions per pt., 91 total) showed a higher congruence with Y-90 PET/MR (5.2 lesions per pt., 82 total) than with BS-SPECT/CT (4.6 lesions per patient, 74 tot.) CONCLUSION: Y-90 PET/MRI showed a higher detection rate and superior image quality of intra- and extrahepatic nuclide depositions after SIRT compared to BS-SPECT. Moreover, there was a higher congruence between pre-treatment Tc-99m HSA-SPECT/CT and Y-90 PET/MR in comparison with BS-SPECT/CT.

OP044

Lean body mass estimation from standard, Dixon-based attenuation correction in combined PET/MRI

I. Rausch[1], P. Rust[2], M. D. DiFranco[1], M. Lassen[1], A. Stadlbauer[3], M. E. Mayerhöfer[3], M. Hartenbach[4], T. Beyer[1]; [1]Center for Medical Physics and Biomedical Engineering, Medical University of Vienna,, Vienna, AUSTRIA, [2]Department of Nutritional Sciences, University of Vienna,, Vienna, AUSTRIA, [3]Department of Biomedical Imaging and Image-guided Therapy, Medical University of Vienna, Vienna, AUSTRIA, [4]Division of Nuclear Medicine, Department of Biomedical Imaging and Image-guided Therapy, Medical University of Vienna, Vienna, AUSTRIA.

Aim: Standardized Uptake Values (SUV) normalized to lean body mass (LBM) may correlate better with the metabolic activity as SUVs normalized to body weight (BW). However, patient-specific LBM calculations are based on general assumptions. Here, we evaluate if the information obtained in PET/MR imaging from standard, MR-based attenuation correction (MR-AC) can be used to predict LBM for each patient more accurately. Method: 10 volunteers (5m, 5f) who underwent a body composition measurement using a BODPOD system (Life Measurement) were included in this study. Subjects were scanned within ±3 days in a PET/MR system (mMR, Siemens Healthcare) from head to toe using MR head and surface coils. Three consecutive multi-bed acquisitions of the MR-AC image data were acquired in free breathing, except for the thorax (full-inspiration breath-hold) using the standard DIXON MR-AC protocol. For each subject and MR-AC map, the following compartmental volumes were calculated using Matlab (MathWorks): whole-body (WB), soft tissue (ST), fat (F), and intermediate tissue (IM), with the latter comprising voxels interpolated between (F) and (ST). We report intra-subject differences in WB and sub-compartmental volumes (ST, F and IM) relative to the WB volume by means of coefficients of variation (CV). The LBM was calculated from the MR-AC by the formula: $LBM\text{-}AC=(ST*\rho ST+IM*\rho IM*1/2)/(ST*\rho ST+F*\rho F+IM*\rho IM)*BW$, were ρ is the tissue-dependent density ($\rho ST=1.1$ kg/L, $\rho F=0.9$ kg/L, $\rho IM=1$ kg/L). Pearson's correlation was calculated between LBM-BODPOD, LBM-AC and LBM estimated by an estimation formula (Sugawara 1999) (LBM-Formula). Linear regression

(avoiding intercept) was used to scale LBM-AC to LBM-BODPOD. Results: Mean CV for all 30 scans was 2.1±1.9% (WB). When excluding the AC-maps with missing tissue artifacts (MT) the CV was reduced to 0.3±0.2% (WB). Mean CV for sub-compartments (all maps, maps without (MT) and tissue swap artifacts (TS)) were: ST (0.9±1.1, 0.7±0.7%), F (2.9 ±4.1, 1.3±1.0%), and IM (3.6±3.7, 1.3±0.7%). Correlation analysis showed better correlation between LBM-AC and LBM-BODPOD ($r=0.99$, $p<0.001$ / excluding MT&TS: $r=0.99$, $p<0.001$) than between LBM-BODPOD and LBM-Formula ($r=0.89$, $p<0.001$ / excluding MT&TS: $r=0.91$, $p<0.001$). Linear regression of data excluding MT&TS results in a scaling factor of 1.08 for LBM-AC . Conclusion: LBM estimation from DIXON MR-AC maps correlates well with standard LBM measurements and, thus, offers routine SUV-LBM-based quantification in PET/MR.

OP045

Semi-quantitative assessment of 18F FDG uptake in the normal skeleton using simultaneous PET/MRI: initial comparison to PET/CT in 50 patients

G. Xu, R. Minamimoto, A. Quon, E. Mittra, **A. Iagaru**; Stanford University School of Medicine, STANFORD, CA, UNITED STATES.

Introduction: Differences in the attenuation correction methods between clinical PET/CT scanners and newly introduced whole-body simultaneous PET/MRI systems could affect the estimated specific uptake values in normal and pathologic structures. Here we evaluated the semi-quantitative 18F-FDG measurements on PET/MRI vs. PET/CT. Materials and methods: Fifty consecutive cancer patients were enrolled in a PET/MRI vs. PET/CT comparison research protocol. First, a PET/CT scan (GE Discovery 600 or 690) was acquired at mean±SD: 73±16 min after FDG injection, followed by PET/MRI scan at 161±31 min after FDG injection. Ten regions of interest (ROIs) in representative areas of the axial and proximal appendicular skeleton were measured from PET in PET/MRI and PET/CT for every patient. In addition, another dataset from 30 patients who had dual time PET/CT was used for comparison. The latter had similar delays between scans as from PET/CT to PET/MRI. SUVmax and SUVmean from the selected ROIs were used for an analysis using Pearson correlation coefficients (CCs). Results: SUVmax values for the normal skeleton obtained from PET/MRI and PET/CT showed good agreement (CC=0.84), similar to the values from the dual time point PET/CT study (CC=0.85). However, the SUVmean values were significantly more variable by PET/MRI compared with PET/CT (CC 0.88 vs. 0.94, $P = 0.006$). No significant differences were noted in either the SUVmax or SUVmean values across all ROIs between PET/MRI and PET/CT exams. Conclusion: Our data demonstrate reliable quantification in the normal skeleton for the simultaneous PET/MRI studies in comparison with PET/CT. The SUVmax is less variable than SUVmean in this cohort. Evaluation of semi-quantitative measurements in malignant bone lesions should also be done.

OP046

Evaluation of the influence of truncation artifacts using in-vivo based quantification accuracy methods in combined PET/MRI

J. Maus[1], G. Schramm[2,1], F. Hofheinz[1], L. Oehme[3], A. Lougovski[1], J. Petr[1], I. Platzek[4], B. Beuthien-Baumann[3], J. Steinbach[1], J. Kotzerke[3], J. van den Hoff[1,3]; [1]PET Center, Helmholtz-Zentrum Dresden-Rossendorf, Dresden, GERMANY, [2]Medical Imaging Research Center, KU Leuven, Leuven, BELGIUM, [3]Department of Nuclear Medicine, University Hospital Carl Gustav Carus, Technische Universität Dresden, Dresden, GERMANY, [4]Department of Radiology, University Hospital Carl Gustav Carus, Technische Universität Dresden, Dresden, GERMANY.

Aim: Quantitative accuracy of standardized uptake values (SUV) and tracer kinetic uptake parameters in patient investigations requires determination of regional activity concentrations in PET data. This determination rests on the assumption that the scanner calibration is valid in-vivo. In a recent study we introduced a method to test this assumption. For 3 different PET and PET/CT systems the activity concentration of urine samples measured in a well-counter were compared to those derived from PET images of the bladder. The study demonstrated a low but systematic underestimation of 7-12% of PET relative to a cross-calibrated well-counter for 56 subjects. In the present study we have applied this method to the Philips Ingenuity-TF PET/MR to evalute the impact of MR-based truncation artifcats on the overall quantitative accuracy of this system. Methods: 21 clinical whole-body F18-FDG scans were included in this study. The bladder region was imaged as the last bed position and urine samples were collected afterwards. PET images were reconstructed including MR-based attenuation correction with and without truncation compensation and 3D region-of-interests (ROI) of the bladder were delineated by 3 observers. Activity concentrations were determined in the PET images for the bladder as well as for the urine by measuring the samples in a well-counter. Results: The in-vivo activity concentrations of the bladder were significantly lower in PET/MR than in the well-counter with a ratio of the former to the latter of 0.756±0.060 (mean±std.dev.) and a range of

[0.604-0.858]. Linearity scans revealed a systematic error of 8-11 % (avg. 9 %). After correcting for this systematic bias caused by shortcomings of the manufacturer's calibration procedure the PET to well-counter ratio increased to 0.832±0.064 [0.668-0.941]. After applying compensation for truncation of the upper extremities in the MR-based attenuation maps the ratio further increased to 0.871±0.069 [0.693-0.992]. Conclusions: Our results show, that the Ingenuity-TF PET/MR underestimates activity concentrations in the bladder by 17% which is 7 percentage points larger than in the previously investigated PET/CT systems. This difference in behavior can be attributed to remaining limitations of MR-based attenuation correction as our results on truncation compensation related influences suggest - leaving only a 2 pp. larger underestimation of activity concentrations if corrected. Thus, quantification accuracy of the Ingenuity-TF PET/MR can be considered acceptable for clinical purposes. The comparison of PET images from the bladder region with urine samples has proven a useful method to evaluate quantification accuracy of different PET systems in-vivo.

OP047

Improvements in PET Image quality from TOF PET/MRI

R. Minamimoto, M. Jamali, A. Barkhodari, D. Holley, G. Zaharchuk, C. Levin, **A. Iagaru**; Stanford University, STANFORD, CA, UNITED STATES.

Purpose: A completely novel integrated PET/MRI scanner with TOF technology has been recently introduced. Here we evaluated the potential of TOF PET/MRI to reduce various PET image artifacts, by comparing the images to non-TOF PET/MRI, TOF PET/CT and non-TOF PET/CT. Materials and methods: All patients underwent a single-injection of FDG, followed first by PET-CT and subsequently by PET-MRI scan. The standard of care PET/CT exams were performed using a GE Discovery 690 PET/CT scanner. The research PET/MRI images were acquired on a GE Signa PET/MRI scanner. All PET images were reconstructed with and without the TOF data, resulting in 4 series of PET images (TOF PET/MRI, non-TOF PE/MRI, TOF PET/CT and non-TOF PET/CT). Visual analysis of these series was performed for 1) dental metal artifacts, 2) breathing artifacts, and 3) scatter artifacts caused by high excretion of FDG in the bladder. PET image quality was evaluated using a 3-point scale (1 - clinically significant artifact; 2 - non clinically-significant artifact; and 3 - no artifact). Results: Data from 25 oncologic patients (mean ± SD age: 56 ± 13 years; female 10, male 15) were used. The average scores of TOF PET/MRI, non-TOF PET/MRI, TOF PET/CT and non-TOF PET/CT for dental artifacts were 2.8, 2.5, 2.4 and 2.3, respectively; for breathing artifacts were 2.8, 2.5, 2.2 and 1.9, respectively; and for pelvic artifacts were 2.7, 1.7, 2.0 and 1.3, respectively. TOF PET/MRI images had the highest image quality scores among the 4 series of PET data analyzed for these types of artifacts. Conclusion: TOF PET/MRI showed promising results in reduction of various PET artifacts in this cohort, when compared to non-TOF PET/MRI, TOF PET/CT and non-TOF PET/CT.

In vivo evaluation of [^{11}C]preladenant for imaging of adenosine A_{2A} receptors in the conscious monkey

X. Zhou[1], E. de Vries[1], K. Ishiwata[2], R. Dierckx[1], S. Nishiyama[3], H. Tsukada[3], P. Elsinga[1]; [1]University Medical Center Groningen, Groningen, NETHERLANDS, [2]Research Team for Neuroimaging, Tokyo Metropolitan Institute of Gerontology, Tokyo, JAPAN, [3]Central Research Laboratory, Hamamatsu Photonics K.K., Hamamatsu, JAPAN.

Aims: The adenosine A_{2A} receptor ($A_{2A}R$) is studied as a therapeutic target in several neurologic and psychiatric disorders. Recently, we have synthesized [^{11}C]preladenant, a PET ligand with high affinity and selectivity for the $A_{2A}R$. The present study aims to evaluate [^{11}C]preladenant in conscious monkey brain. Materials and methods: Conscious monkeys (n=6) were *i.v.* injected with [^{11}C]preladenant and a 90 min dynamic scan was started. Arterial blood samples with metabolite analysis were obtained during the scan to provide the input function for kinetic modelling. Distribution volume (V_T) was obtained by modelling with the Logan graphical analysis with t* set to 22 min post injection. Simplified reference tissue model (SRTM) and multilinear reference tissue model (MRTM) were used to estimate binding potential (BP_{ND}) in striatum. Cerebellum, cingulate, parental cortex and occipital cortex were tested as reference regions. The values of BP_{ND} obtained from reference tissue-based models were compared with the BP_{ND} calculated from Logan analysis using the formula $V_{T,\ target}/V_{T,\ reference}$-1. The best reference tissue was selected based on high BP_{ND} in striatum with low intra-individual variance. Results: Regional uptake of [^{11}C]preladenant was consistent with the distribution of $A_{2A}Rs$ in the monkey brain, with the highest uptake in putamen, followed by caudate, and the lowest uptake in cerebellum. The tracer kinetics was well fitted with the Logan plot. V_T estimates ranged from 0.89±0.31 in cerebellum to 5.86±2.10 in putamen. BP_{ND} values estimated from SRTM and MRTM were comparable, with slightly higher (1-3%) values predicted

by MRTM. Striatal BP_{ND} predictions with SRTM (5.05±1.01 and 4.02±1.06, for putamen and caudate, respectively) and MRTM (5.11±1.00 and 4.10±1.05, for putamen and caudate, respectively) were in agreement with BP_{ND} calculated from Logan analysis (5.64±1.54 and 4.12±1.26, for putamen and caudate, respectively), but with a small negative and significant ($p<0.05$) bias of <10%, when cerebellum was used as the reference region. As a trade-off between bias and noise, coefficient of variance (COV) of BP_{ND} predicted by SRTM and MRTM (~20%) was smaller compared with BP_{ND} estimate from Logan analysis (~28%). Other reference regions showed an increased (7-20%) negative bias of BP_{ND} prediction, compared with cerebellum prediction. Compared to V_T, BP_{ND} seemed to be a more stable parameter with smaller COV in striatum (~20% BP_{ND} COV vs. ~35% V_T COV in striatum). Conclusions: [^{11}C]Preladenant PET is suitable to non-invasively quantify A_{2A}Rs in monkey brain. MRTM and SRTM using cerebellum as the reference tissue are applicable models for A_{2A}R quantification.

OP049

Sigma-1 and dopamine D2 receptor occupancy of the dopamine stabilizer pridopidine in the brain of living rats

K. Sahlholm[1], J. W. A. Sijbesma[2], B. Maas[2], C. Kwizera[2], N. K. Ramakrishnan[2], R. A. J. O. Dierckx[2], P. H. Elsinga[2], A. Van Waarde[2]; [1]Department of Neuroscience, Karolinska Institute, Stockholm, SWEDEN, [2]University of Groningen, University Medical Center Groningen, Department of Nuclear Medicine and Molecular Imaging, Groningen, NETHERLANDS.

Objectives: Dopamine stabilizers have stimulatory actions under low dopamine tone and inhibitory actions under high dopamine tone without eliciting catalepsy. Pro-mnemonic and neuroprotective effects have also been attributed to these compounds, which are either neutral antagonists or partial agonists at the dopamine D2 receptor. The mechanism underlying their stimulatory and neuroprotective actions is unknown but could involve sigma-1 agonism, since these drugs have shown nanomolar in vitro affinity to sigma-1 receptors. In order to test this hypothesis, we examined the dose-dependent D2R and sigma1R occupancy of the dopamine stabilizer pridopidine (ACR16) in living rats. Methods: Male Wistar rats were treated with various doses of pridopidine (0, 3, or 15 mg/kg, s.c.), one hour before injection of the sigma1R ligand [11C]SA4503 or the dopamine D2R ligand [11C]raclopride. Some animals received 60 mg/kg pridopidine and were only scanned with [11C]raclopride. Dynamic microPET scans were made with a Siemens/Concorde Focus220 camera. Cerebral [11C]SA4503 binding was quantified using plasma input data acquired by arterial sampling and distribution volume (VT) calculated by Logan graphical analysis. Striatal [11C]raclopride binding was quantified using target-to-cerebellum ratios and binding potentials calculated with a simplified reference tissue model. RESULTS: Pridopidine dose-dependently reduced the VT of [11C]SA4503 in all examined areas of the rat brain. Particularly at the 15 mg/kg dose, pridopidine reduced the clearance of radioactivity from plasma and increased the metabolic degradation of [11C]SA4503 (parent fraction at 60 min 33% vs 55% at baseline). Cunningham-Lassen plots based on regional VT and metabolite-corrected plasma input data indicated sigma-1 receptor occupancies of 57 ± 2% and 85 ± 2% after pretreatment of animals with 3 and 15 mg/kg pridopidine. These drug doses did not reduce [11C]raclopride binding in the striatum, but at 60 mg/kg, pridopidine caused a significant reduction of the target-to-nontarget ratio of the D2 ligand (from 3.85 ± 0.48 to 1.96 ± 0.10), reflecting 66% D2R occupancy. Conclusions: At therapeutically effective doses, pridopidine occupied a high fraction of the sigma1R population and a negligible fraction of the dopamine D2R population in rat brain. Significant occupancy of dopamine D2 receptors was only observed at a dose of pridopidine 20-fold higher than was required for occupancy of sigma-1 receptors. The characteristic actions of dopamine stabilizers may result from the combination of high sigma-1 affinity (possibly sigma-1 agonism) with low-affinity dopamine D2 antagonism.

OP050

PET/MR hybrid scanner imaging of cerebral blood flow using 15O-water positron emission tomography and arterial spin labeling magnetic resonance imaging in newborn piglets

J. B. Andersen[1], W. Henning[1], U. Lindberg[2], C. N. Ladefoged[1], L. Højgaard[1], G. Greisen[3], I. Law[1]; [1]Department of Clinical Physiology, Nuclear Medicine and PET, Rigshospitalet, University of Copenhagen, Denmark, København Ø, DENMARK, [2]Functional Imaging Unit, Rigshospitalet, Glostrup Hospital, University of Copenhagen, Denmark, København Ø, DENMARK, [3]Department of Neonatology, Rigshospitalet, University of Copenhagen, Denmark, København Ø, DENMARK.

Aim: Abnormality in cerebral blood flow (CBF) distribution can lead to hypoxic-ischemic damage in newborn infants and is a major cause of later neurocognitive impairment. Thus, a clinically useful, robust and accurate method for measuring CBF in newborn infants is needed. The aim of the study was to investigate minimally invasive approaches to measure CBF by comparing simultaneous 15O-water positron emission tomography (PET) and single-TI pulsed arterial spin labeling (ASL) magnetic resonance imaging (MR) on a hybrid PET/

MR system in seven newborn piglets. Materials and methods: The experimental protocol for the study was approved by the Danish Animal Experiments Inspectorate and conducted in accordance with the Animal Ethics Policy at the University of Copenhagen. On each piglet, four scans at baseline and four scans after acetazolamide stimulus were performed. Positron emission tomography was performed with repeated IV injections of 20 and 100 MBq 15O-water to test CBF reliability at low activity injections. Cerebral blood flow was quantified using a 1-tissue-compartment model employing two different input functions: either an arterial input function (AIF) or an alternative image derived input function (IDIF) generated from the dynamic PET scan using a VOI in the left ventricle of the heart. Results: The mean global CBF(95%CI) PET-AIF, PET-IDIF and ASL at baseline were 27(23;32), 34(31;37) and 27(22;32) mL/100g/min, respectively. At acetazolamide stimulus PET-AIF, PET-IDIF and ASL were 64(55;74), 76(70;83) and 79(67;92) mL/100g/min, respectively. At baseline the differences between PET-AIF, PET-IDIF and ASL were 22%($p<0.0001$) and -0.7%($p=0.9$). At acetazolamide the differences between PET-AIF, PET-IDIF and ASL were 19%($p=0.001$) and 24%($p=0.0003$). ASL CBF showed the largest variance when accounting for dose and acetazolamide effect ($p=0.01$). There was no significant difference in variation between the 20 MBq PET CBF scans compared to the 100 MBq PET CBF scans ($p=0.06$). On visual presentation the distribution of regional CBF showed that the variation across voxels was greater in ASL CBF images with both very high and negative value voxels. Conclusion: In conclusion, PET-IDIF overestimated global CBF. An injected activity of 20 MBq 15O-water had acceptable concordance with 100 MBq, and may be used clinically without compromising image quality. Global ASL CBF and PET CBF were congruent during baseline but not during hyperperfusion. Single-TI ASL was questionable for regional CBF measurements. Further evaluation of the regional accuracy of ASL CBF and PET CBF is needed in newborn infants with low absolute rates of flow.

OP051

PET Imaging of Tau Pathology in two Transgenic Mouse Models using [^{18}F]-THK-5117

M. Brendel[1], A. Jaworska[2], F. Probst[1], F. Overhoff[1], J. Carlsen[1], S. Lindner[1], J. Herms[2], P. Bartenstein[1], N. Okamura[3], **A. Rominger**[1]; [1]University of Munich, Munich, GERMANY, [2]DZNE, Munich, GERMANY, [3]Tohoku University, Sendai, JAPAN.

Aims: Abnormal accumulation of tau aggregates in brain is one of the hallmarks of Alzheimer's disease (AD). To visualize the tau deposition in vivo, a previously developed 2-arylquinoline derivative [^{18}F]-THK-5117 was evaluated in two transgenic tau mouse models using μPET in combination with autoradiography and histopathology. Methods: μPET scans were performed in P301S (N=11) and BiGT animals (N=16) of different age groups. For control groups age- and background-matched wild-type (WT) littermates were used. After i.v. application of 16 ± 2 MBq [^{18}F]-THK-5117 a dynamic 90 min (20-50 min for BiGT) emission recording was initiated followed by a 15 min transmission scan using the Siemens Inveon DPET. After coregistration to an MRI atlas and cerebellar scaling, volume-of-interest based analysis (SUVR) and statistical parametric mapping (SPM) were performed. PET results were compared with ex vivo and in vitro autoradiography and validated with AT8 staining for neurofibrillary tangles. Results: Emission time from 20-50 min showed suitability for static economized PET recordings and test-retest analyses revealed robust SUVR values ($r=0.9$). SUVR increases were detected in the brainstem of P301S mice (+11%; $p < 0.001$) compared to WT animals. In BiGT animals significant increases in SUVR were found in entorhinal/amygdaloidal areas (+15%; $p < 0.001$) when compared to WT. Histologically assessed tau loads correlated well with PET-SUVR for P301S ($r=0.8$; $p<0.001$) and BiGT ($r=0.7$; $p<0.001$) mice while distribution patterns of AT8 positive tau were reflected by SPM analyses. In vivo PET findings could be verified by autoradiography where blocking with cold tracer proved the specificity to tau depostitions. Conclusions: [^{18}F]-THK-5117 is a promising PET tracer and suitable for preclinical tau imaging in the mouse brain. Pathology-related effects could be successfully imaged in vivo in two transgenic tau models, where in vivo assessment of the given inter-animal heterogeneity can potentially improve subsequent treatment studies in the future.

OP052

Altered brain serotoninergic neurotransmission and glucose metabolism in an original mouse model of synucleinopathy

E. LEVIGOUREUX[1], C. BOUILLOT[2], T. BARON[3], **L. ZIMMER**[1], S. LANCELOT[1]; [1]Université Claude Bernard Lyon 1, Lyon, FRANCE, [2]CERMEP-Imaging Platform, Lyon, FRANCE, [3]ANSES, Lyon, FRANCE.

Aim: Alpha-synuclein (α-syn) aggregation is a neuropathological hallmark of neurodegenerative diseases called synucleinopathies, including Parkinson's disease, dementia with Lewy bodies and multiple system atrophy. The purpose of this study was to evaluate serotoninergic and metabolic disorders in an original mouse model of synucleinopathy. Materials and methods: This study used a model of transgenic mouse (TgM83) expressing in an accelerated manner the

human A53T mutated α-syn. Control animals were C57Bl/6S mice presenting a deletion of the α-syn locus (KO α-syn) and C57Bl/6S mice (wild type). MicroPET acquisitions were performed with [18F]MPPF, a serotonin 5HT1A receptor radiopharmaceutical, [11C]DASB, a serotonin transporter radiopharmaceutical and [18F]FDG. Regions of interest were drawn manually according to the stereotaxic atlas and anatomical MRI acquisitions. Regional standardized uptake value ratio (SUVR)s were calculated and normalized to cerebellar cortices for [11C]DASB and to temporal cortices for [18F]FDG. For [18F]MPPF, images were analyzed with Logan BP and normalized to cerebellar cortices. Results: MicroPET images showed an increased uptake of [18F]MPPF in this mouse model of synucleinopathy. In TgM83 mice BP were 0.96, 0.76 and 0.96 in the hippocampus, cingulate cortex and frontal cortex, respectively, versus 0.54 ($p<0.0001$), 0.45 ($p=0.0001$) and 0.65 ($p=0.0002$) in WT mice and 0.44 ($p<0.0001$), 0.39 ($p=0.0001$) and 0.73 ($p=0.0133$) in KO α-syn mice. Conversely, a hypometabolism of glucose was observed in TgM83 mice in the same regions: SUVR were 1.26, 1.26, 1.22 in hippocampus, cingulate cortices and frontal cortices, respectively, versus 1.35 ($p=0.0001$), 1.46 ($p<0.0001$) and 1.33 ($p=0.0136$) in WT mice and 1.39 ($p=0.04$), 1.52 ($p=0.0003$) and 1.34 ($p=0.05$) in KO α-syn mice. No significant differences were observed between the three groups for [11C]DASB uptake. Conclusion: Our results demonstrated in a mouse model of synucleinopathy a regional overexpression of 5HT1A receptors, without serotonin transporter modifications and with a carbohydrate hypometabolism. This study revealed for the first time that an overexpression of α-syn modifies the serotonin neurotransmission. Brain serotonin concentrations will be determined to propose a pathophysiological mechanism.

OP053

Longitudinal Imaging of Acute Neuroinflammation with [11C]PBR28 in an Ischemic Stroke Rat Model

M. Tóth[1], P. Little[1,2], F. Arnberg[1,2,3], J. Häggkvist[1], J. Mulder[4], A. Varrone[1], C. Halldin[1,5], B. Gulyás[1,5], S. Holmin[1,2]; [1]Karolinska Institutet, Department of Clinical Neuroscience, Stockholm, SWEDEN, [2]Karolinska University Hospital, Department of Neuroradiology, Stockholm, SWEDEN, [3]Karolinska University Hospital, Department of Radiology, Stockholm, SWEDEN, [4]Karolinska Institutet, Department of Neuroscience, Stockholm, SWEDEN, [5]Imperial College-NTU, Lee Kong Chian School of Medicine, Singapore, SINGAPORE.

Aim: Adequate estimation of neuroinflammatory processes following ischemic stroke is essential for better understanding of disease mechanisms, and for the development of treatment strategies. With [11C]PBR28, we have monitored the inflammatory response after transient cerebral ischemia in rats longitudinally, using a recently developed rat stroke model with isolated focal cortical infarcts. Our aim was to compare the suitability of BPND as an outcome measure compared to %SUV, in this novel animal model. Matherials and Methods: Six Sprague-Dawley rats (300-400g) were anaesthetized with isoflurane in 100% O2. Occlusion of the M2 segment of the middle cerebral artery (M2CAO) was maintained for 90 min, and animals were imaged at 1, 4, 7 and 14 days after reperfusion (one animal missing day 14) with a bolus injection of [11C]PBR28 through tail vein cannulation in nanoScan PET/MRI and PET/CT systems (Mediso Ltd, Budapest Hungary). PET scans were co-registered to individual T1-weighted MRI images in PMOD 3.3 (Zurich, Switzerland). As a primary outcome BPND was estimated with SRTM, using the contralateral cortex as reference region. Results: [11C]PBR28 showed high uptake in the Infarct region from day 4 with gradual decrease at later time points. The following average %SUV values were obtained from the Infarct region on day 1: 67.21 ± 3.68 (n = 6), day 4: 151.16 ± 41.59 (n = 6), day 7: 141.02 ± 51.56 (n = 6) and day 14: 124.59 ± 33.29 (n = 5). At day 4, 7 and 14 there was a significantly increased uptake of [11C]PBR28 compared to day 1, while have found no significant change in the uptake of Contralateral Cortex during the 14 days of imaging. BPND in the Infarct region was 0.22 ± 0.19 (n = 6) on day 1 and similarly to %SUV there was a significant increase in BPND on day 4: 1.73 ± 0.78 (n = 6), day 7: 1.59 ± 0.96 (n = 6) and day 14: 0.86 ± 0.64 (n = 5) compared to day 1. Conclusion: The longitudinal follow up of inflammatory response with the TSPO radioligand [11C]PBR28 in rats after cerebral ischemia showed significantly up-regulated TSPO binding in the Infarct region from day 4, with both %SUV and BPND. This activation gradually decreased between day 4 and day 14. The present model (M2CAO) appears to be well suited for studies on neuroinflammation with a more rapid response compared to the MCAO model.

OP054

Evaluation of the effect of radiotherapy on neuronal integrity in rats using [11C]flumazenil PET

A. Parente, D. Vallez Garcia, P. van Luijk, J. A. Langendijk, R. A. J. O. Dierckx, J. Doorduin, E. F. J. de Vries; RUG, Groningen, NETHERLANDS.

Aim: Whole brain radiotherapy is frequently used in the treatment of primary and metastatic brain tumors. Unfortunately, radiotherapy also damages normal brain tissue, which can lead to serious and debilitating cognitive dysfunction. The exact mechanisms behind the radiotherapy-induced cognitive dysfunction remain elusive, but it may, in part, be explained by

neuronal damage and neuronal loss. The aim of this study was therefore to evaluate if whole brain radiotherapy induced neuronal loss in healthy rats, using PET with the GABAA receptor antagonist [11C]flumazenil as a marker for neuronal loss. Material and methods: Male Wistar rats (n=24, age 8-9 weeks) were divided in 3 groups of 8 rats: control, sham irradiated, and whole brain irradiated. Whole brain irradiation was performed by the delivery of 25 Gy of X-rays in a single dose, under anesthesia, using an in-house developed rat brain collimator so that only the brain was exposed. Sham irradiated rats underwent the same procedure, but were not irradiated. [11C]Flumazenil PET scans were performed 3 months after (sham-)irradiation. Control rats were scanned at an age of 8-9 weeks to assess the effect of aging on [11C]flumazenil PET. [11C]Flumazenil was injected intravenously at a constant flow of 1 ml/min (62±26MBq) and a dynamic PET scan of 60 minutes was acquired. The PET scan was accompanied by arterial blood sampling and metabolite analysis. One-tissue compartment modeling was used to calculate the volume of distribution (VT) in different brain regions, using blood and metabolite corrected plasma as input. Results: In control rats, the highest VT was found in the frontal cortex (12.0±2.0) and hippocampus (11.0±1.8) and the lowest in the pons (4.9±0.8) and medulla (4.2±0.7). No statistical significant differences in the VT were found between control and sham irradiated rats, showing that aging did not affect [11C]flumazenil binding. However, the VT in rats irradiated with 25 Gy was statistically significantly lower in all brain regions ($p<0.05$), including frontal cortex (33%), hippocampus (32%), pons (33%), and medulla (35%), when compared to sham irradiated rats. Conclusion: Whole brain irradiation resulted in statistically significantly decreased binding of [11C]flumazenil to GABAA receptor. This finding suggests that radiotherapy-induced cognitive dysfunction could be related to neuronal loss.

OP055

Inverse translation of PET auditory system activation studies to rats using F-18-FDG PET

M. Mamach[1,2], G. Berding[1,2], J. P. Bankstahl[1], F. Wilke[1], L. Geworski[1], F. M. Bengel[1], S. Kurt[1,2]; [1]Medical School, Hannover, GERMANY, [2]Cluster of Excellence "Hearing4All", Oldenburg, GERMANY.

Aim:Functionality assessments of the auditory system using statistical parametric mapping (SPM) with multiple PET activation studies of a patient with moderate auditory stimuli are standard in humans. We performed an adapted inverse translation of this method to healthy, auditory unimpaired rats and assessed its functionality and magnitude.Methods:Scans were performed in 12 female Sprague Dawley rats using F-18-fluorodeoxyglucose (FDG, 16-20 MBq) PET (Inveon, Siemens). The tracer was always injected via tail vein in awake animals placed into a motion restricting tube within a sound attenuated box. Three sets of separate scans were acquired for each animal, each under the following conditions: (i) 55 dB background noise (BG55), (ii) 65 dB continuous white noise (WN65) and (iii) 95 dB pulsed rippled noise (RN95). All sound conditions started 1 min before tracer injection and lasted for 41 min. Scanning was performed across 30 min starting 1 h after injection. Data were reconstructed iteratively including 57Co-transmission-source-based attenuation correction. Spatial normalization and brain activity normalization were performed using a FDG template and mask provided by PMOD3.6 software. Mean normalized counts were extracted for auditory regions (inferior colliculus (IC), mediate geniculate body (MGB) and auditory cortex (AC)) using Schwarz's VOI atlas. Pairwise comparisons across conditions assessed differences of relative activities in VOIs and SPM8 based voxel-wise extent and T-value.Results:RN95-vs-BG55 and WN65-vs-BG55 comparisons revealed significant increased uptake by 15.5% and 12.5% in the IC based on VOI analysis ($p<0.001$). Correspondingly, SPM analysis showed suprathreshold voxels in 97% and 77% of this VOI ($p<0.001$), with T-max value of 9.9 and 8.3, respectively. RN95-vs-WN65 and RN95-vs-BG55 showed increased uptake ($p<0.001$) of 6.5% and 5.6% in the MGB - encompassing 35% and 21% of this VOI ($p<0.001$) with a T-max value of 5.0 and 4.3. Comparing RN95-vs-WN65 resulted in an increased uptake ($p<0.05$) in the auditory cortex by 2.8%, corresponding to 1% of this VOI (T-max=3.9, $p<0.001$). Finally, WN65-vs-BG55 revealed decreased uptake ($p<0.001$) in the AC (-2.8%) corresponding to 5% of this VOI (T-max=5.3, $p<0.001$).Conclusions:In contrast to humans, activation in the AC of rats was lower compared to peripheral structures (e.g. IC). A deactivation of the AC was observed with louder continuous stimulus compared to background. Our data demonstrate the ability of FDG PET to detect activations in all observed auditory areas and to differentiate between auditory conditions. This technique may be used to characterize animal models for hearing disorders.

18F-FDG PET/CT as Predictive of Response after Chemoradiation in Esophageal Cancer Patients

E. Elimova, X. Wang, **E. C. Etchebehere**, Y. Shimodaira, H. Shiozaki, R. Wadhwa, V. Planjery, N. Charalampakis, M. A. Blum, W. Hofstetter, J. Lee, B. R. Weston, M. S. Bhutani, H. A. Macapinlac, J. A. Ajani; The University of Texas MD Anderson Cancer Center, Houston, TX, UNITED STATES.

Introduction: The purpose of this study was to evaluate if a baseline, an interim or a post-chemoradiation (CTRT) 18F-FDGPET/CT studies could provide information on pathologic response to CTRT and overall survival (OS). Materials and Methods: Thirty-one patients with histologically proven adenocarcinoma or squamous cell carcinoma of the esophagus, fit for trimodality therapy were prospectively enrolled. Most were men (93.5%), and had a stage III cancer (74.2%). Chemotherapy consisted of oxaliplatin/5-fluorouracil (45.2%) and taxane/5-fluorouracil (54.8%). All patients underwent a baseline, an interim (performed 12+/-2 days after onset of CTRT) and a post-CTRT 18F-FDGPET/CT study. The 18F-FDGPET/CT variables evaluated were at baseline, interim and post-CTRT studies maximum standardized uptake value (SUVmax) and total lesion glycolysis (TLG). Clinical and 18F-FDGPET/CT parameters were correlated with pathologic complete response (pathCR) and OS. Results: Among the 31 patients studied, 61.3% achieved a clinical complete response (cCR) and 87.1% had surgery. The median OS was 35.1 months (95% CI: 19.9 - NA). PathCR rate was 22.2%. There was only a marginal association between cCR and pathCR (p=0.06). None of the other variables was predictive of pCR. There was association between OS and baseline TLG (p=0.03) at the optimal cutoff TLG value of 75.15. Additionally, TLG and αTLG post-CTRT were also associated with OS (p = 0.01 and 0.03, respectively). Conclusion: None of the PET parameters are predictive of pCR but TLG at baseline and post-CTRT are prognostic of OS.

OP057

Diagnostic performance of 18F-fluorothymidine PET/CT for primary gastric cancer and its lymph node metastasis: Comparison with 18F-fluorodeoxyglucose PET/CT

M. Nakajo[1], Y. Kajiya[2], A. Tani[2], M. Jinguji[1], Y. Nakabeppu[1], M. Nakajo[2], S. Shimaoka[3], T. Nihara[3], S. Tanaka[4], T. Yoshiura[1]; [1]Department of Radiology, Kagoshima University, Graduate School of Medical and Dental Sciences, Kagoshima, JAPAN, [2]Department of Radiology, Nanpuh Hospital, Kagoshima, JAPAN, [3]Department of Gastroentenology, Nanpuh Hospital, Kagoshima, JAPAN, [4]Department of Pathology, Nanpuh Hospital, Kagoshima, JAPAN.

Aim: To examine the diagnostic performance of 18F-fluorothymidine (FLT) PET/CT for primary and metastatic lymph node gastric cancer foci by comparing with 18F-fluorodeoxyglucose (FDG) PET/CT. Materials and Methods: The enrolled study population comprised 17 patients with 17 newly diagnosed gastric cancers who underwent surgical resection of primary cancers and regional lymph nodes after both FLT and FDG PET/CT. The SUVmax of primary gastric cancer was compared between FLT PET/CT and FDG PET/CT studies using Wilcoxon signed-rank test. Associations of SUVmax levels with pathological factors were examined using the Mann-Whitney U or the Spearman rank correlation test. Diagnostic indices for detecting nodal metastasis were compared between the two tracers using the McNemar exact. Results: Fourteen of 17 primary cancers were visualized by both FLT and FDG PET/CT studies, and the residual 3 pathologically T1b cancers were not visualized by either method. FLT SUVmax was significantly lower than FDG SUVmax in all of the 14 visible primary cancers (7.1 ± 4.0 vs. 10.2 ± 5.0, p=0.003). The SUVmax was significantly correlated with tumor size for both FLT and FDG (FLT: ρ=0.56, p=0.036, FDG: ρ=0.59, p=0.025), but were not associated with the depth of invasion, nodal metastasis and differentiation. The sensitivity, specificity and accuracy for detecting nodal metastasis were 31.0% (9/29), 100% (166/166) and 89.7% (175/195) for FLT PET/CT, and 44.8% (13/29), 98.7% (164/166) and 90.8% (177/195) for FDG PET/CT, respectively. The sensitivity (p=0.13), specificity (p=0.48) and accuracy (p=1.00) were not significantly different between the two modalities. SUVmax was not significantly different between FLT (4.6 ± 3.1) and FDG (4.2 ± 1.0) (p=0.91) in the 9 concordant true positive nodes. Conclusions: FLT PET/CT has a comparable potential with FDG PET/CT in diagnosing primary and nodal foci of gastric cancer despite significantly lower FLT uptake in the primary foci.

OP058

Role of 18F-FDG PET/CT in predicting pathologic response to neoadjuvant chemo-radiotherapy and survival in patients of non-metastatic esophageal and gastro-esophageal junction carcinoma

A. Pruthi[1], S. Taywade[2], P. S. Choudhury[2]; [1]Sir Ganga Ram Hospital and Research Centre, New Delhi, INDIA, [2]Rajiv Gandhi Cancer Institute & Research Centre, New Delhi, INDIA.

Objective: To assess the role of 18F-FDG PET/CT in predicting the pathologic response and survival of patients with non-metastatic esophageal carcinoma treated with neoadjuvant chemo-radiation (CRT) and esophagectomy. Methods: 32 patients (18 males, 14 females; mean age 56.7 years, median age 58 years) with locally advanced (stage II/ III) esophageal carcinoma who underwent neoadjuvant chemo-radiation (CRT) followed by total esophagectomy at our institute during 2010-13 were analysed. Their pre-treatment staging and post neoadjuvant chemo-radiation 18F-FDG PET/CT studies were re-evaluated by an experienced nuclear medicine physician.

Response to neoadjuvant chemo-radiation on PET/CT images was compared to pathologic response. Follow-up information was obtained after careful evaluation of patient's electronic medical records. Disease free survival was calculated from the day of surgery till the first evidence of recurrence. Various PET/CT findings like SUV max, presence of lymph nodal abnormalities were correlated with pathologic response, incidence of recurrence and disease free survival using appropriate statistical tests. Results: Most tumours were squamous cell carcinomas (29 out of 32; 90.6%) and involved mid-thoracic esophagus (17 out of 32; 53.1%). Post-CRT 18F-FDG PET/CT study identified pathologic response with 76.2% sensitivity, 70% specificity and 74.2% accuracy. However, negative predictive value was only 41.7%. Patients were followed up for median duration of 10.8 months (interquartile range 6.3- 17.7 months). PET/CT parameters like SUVmax and presence of lymph nodal abnormalities in pre-treatment scan didn't show significant correlation with disease free survival. Pathologic response was found to correlate with the post-CRT FDG PET/CT maximal standardized uptake value (SUVmax) ($p<0.05$) and a post-CRT FDG PET SUVmax of >= 4 was found to be the only factor which correlated with reduced disease free survival (1 year survival rate of 25% vs. 68.1%; p value = 0.026). Conclusion: Post chemo-radiation PET/CT was found to be predictive of pathologic response and disease free survival. In view of low negative predictive value, surgery should still be considered even if the post-CRT FDG-PET/CT scan is normal because microscopic residual disease cannot be ruled out.

OP059

Recurrence Detection in Pancreatic Cancer: The Value of Quantitative FDG-PET/CT

J. T. Friis[1], O. S. Bjerring[2], M. G. Hildebrandt[1], S. Hess[1], O. Gerke[1], P. F. Høilund-Carlsen[1]; [1]Dept. of Nuclear Medicine, Odense University Hospital, Odense C, DENMARK, [2]Dept. of Surgery, Odense University Hospital, Odense C, DENMARK.

Aim: FDG-PET/CT is relatively unexplored in pancreatic cancer. The aim of this project was to investigate whether SUV-based semi-quantitative measures obtained by FDG-PET/CT could help differentiate cancer recurrence from non-specific lesions in patients with suspected recurrence of pancreatic cancer.Materials and Methods: As part of an ongoing prospective clinical trial, 25 patients with resectable pancreatic cancer were recruited postoperatively. FDG-PET/CT was performed, as part of protocolled follow-up, 3, 6, 9, 12, 18, and 24 months after surgery; if recurrence occurred, the patients dropped out of the study. The reference standard was a composite decision at a multidisciplinary team conference based on all available data, including follow-up scans and biopsies, when available. FDG-PET/CT scans were as-sessed visually by experienced nuclear medicine physicians and dichotomized into 'recurrence' or 'no recurrence'. In patients with recurrence, only the last scan leading to the diagnosis was included in the analysis. In patients without recurrence, any scan with a positive lesion was registered, and the one with the most FDG-avid lesion was included in the analysis. The FDG-uptake in suspicious lesions was characterized by the SUVmax value and the partial volume corrected SUVmean (cSUVmean) value. If a scan had no lesions suspicious of malignancy (true or false negatives), a value of '0' was imputed. Outcome measures were sensitivity and specificity and receiver operating characteristic (ROC) analysis of SUV measures with values of area under the curve (AUC).Results: Of the 25 patients, 16 were diagnosed with recurrence during the study period, while 9 remained disease free. Sensitivity and specificity were 0.88 (95% CI: 0.62-0.98) and 0.33 (0.07-0.70), respectively. Median SUVmax values in false positive and true positive lesions were 4.1 (3.3-16.8) and 7.0 (4.7-20.5), respectively ($p<0.04$). Median cSUVmean values in false positive and true positive lesions were 3.8 (range 3.6-10.7) and 6.6 (3.5-20.4), respectively ($p<0.04$). ROC analysis of cSUVmean values had an AUC of 0.75 (0.53-0.97) and a sensitivity and specificity of 0.81 and 0.78 with an optimal cSUVmean cut-off set at 4.4.Conclusion: Visual assessment of FDG-PET/CT imaging for recurrent pancreatic cancer had a high sensitivity, but a low specificity and, therefore, seems not suited for the detection of recurrent pancreatic cancer. Mean SUVmax and cSUVmean were significantly higher in malignant than benign lesions, albeit with wide ranges. Quantification seemed to increase specificity and may, thus, be considered helpful for differentiating malignant from benign lesions.

OP060

Contribution of 18F-FDG PET/CT in patients suspected for colorectal cancer recurrence, with normal or increased CEA.

H. Balink[1], E. van der Zee[1], J. P. E. N. Pierie[1], R. J. Bennink[2], H. J. Verberne[1]; [1]Medical Center Leeuwarden, Leeuwarden, NETHERLANDS, [2]Academic Medical Center, University of Amsterdam, Amsterdam, NETHERLANDS.

Objective: Colorectal cancer (CRC) is an increasing health problem, in particular in developed countries. Patients with a history of primary CRC surgically treated with the intention of curation benefit from an optimal postoperative follow-up. The current Dutch guidelines recommend computed tomography (CT) as the imaging modality of choice, whether or not indicated by an elevated carcinoembryonic antigen (CEA) level.

However, ^{18}F-fluorodeoxyglucose (^{18}F-FDG) positron emission tomography (PET)/CT, seems to have a better diagnostic precision than CT in detecting CRC recurrence. The objective of this retrospective study was to evaluate the diagnostic precision of ^{18}F-FDG PET/CT in detecting CRC recurrence during follow-up, after the primary CRC was surgically treated with curative intention. Patients were included with either a normal CEA level (and with equivocal radiology findings), or elevated CEA levels. Methods: In total 124 were included. All patients with suspected recurrence of CRC during follow-up were subjected to ^{18}F-FDG PET/CT imaging. A total of 124 ^{18}F-FDG PET/CT scans were assessed and the ^{18}F-FDG PET/CT outcome was subsequently verified based on the findings during the follow-up period after ^{18}F-FDG PET/CT. Results: In the overall population, with a proven CRC recurrence prevalence of 68,6% (n = 85), ^{18}F-FDG PET/CT had an overall sensitivity, specificity, and accuracy of 94,1% , 82,1% and 90, 3% respectively. As expected patients with a normal CEA level (n = 25) had a lower CRC recurrence prevalence compared to those with an elevated CEA level (n = 94) (48% vs. 72%, p = 0.021). ^{18}F-FDG PET/CT in CEA normal patients had a sensitivity, specificity, and accuracy of 91.7%, 84.6% and 88%, and for those patients with an elevated CEA level these values were 94,1%, 80,8% and 90,4%, respectively.Conclusions: ^{18}F-FDG PET/CT showed, irrespective of CEA levels, a high diagnostic accuracy in detecting or excluding CRC recurrence during postoperative follow-up. However these retrospective data should be regarded as preliminary and the role of ^{18}F-FDG PET/CT as the imaging modality of choice in patients suspected for CRC recurrence needs to be confirmed in prospective trials.

OP061

Evaluating Quantitative Measures in Incidental Colorectal PET Findings

T. Nguyen, S. Hess, H. Petersen, P. F. Hoeilund-Carlsen; Dept. of Nuclear Medicine, Odense University Hospital, Odense, DENMARK.

Aim: In oncologic PET, SUV_{max} and SUV cutoff values to distinguish malignant from benign lesions are often reported. However, studies have repeatedly questioned their validity as their reliability and comparability are influenced by many factors. We investigated such measures of common quantitative analysis in incidental colorectal (ICR) findings using dedicated software.**Materials and Methods**: FDG-PET studies in 24 patients with ICR uptake and 28 lesions (8 colorectal cancers, 12 polyps, and 8 with only benign findings) were retrospectively analyzed. To test analysis method variability, two lesion delineation techniques were applied with dedicated software (ROVER, ABX, Radeberg, Germany) using background corrected lesion-based threshold (LT) and voxel-based threshold (VT). A built-in partial-volume correction (PVC) was also employed and lesion measures of SUV_{max}, SUV_{mean}, $SUV_{mean, PVC}$, metabolically active volume (MAV), and mean metabolic volumetric product ($MVP_{mean} = SUV_{mean}$ MAV) were extracted.**Results**: In all lesions, $SUV_{max} > 5$ and $SUV_{mean} \geqq 3$. Measured SUV_{max} values were reproducible and malignant measures (16.5 ± 6.1) were higher than benign (10.2 ± 3.7) levels (p = 0.04), but none of them deviated (p = 0.3-0.7) from those of polyps (15.1 ± 7.5). SUV_{mean} values in malignant (LT: 10.2 ± 3.4, VT: 8.8 ± 2.8) compared to benign (LT: 6.5 ± 2.3, VT: 6.2 ±2.2) findings were also higher (p = 0.03-0.07) and both were indistinctive (p = 0.3-1) from those of polyps (LT: 10 ± 5.2, VT: 9.5 ± 5). The differences between VT and LT methods (p = 0.4-1) did not alter overall relations. Some malignant MAV and MVP_{mean} peaks were well above those of polyps and benign findings, both of which were at similar levels. PVC generally increased values by a factor of 1.3-2.7 ($p < 0.01$) at preserved relative levels. Inter-group relations for all measures, however, were insignificant (p = 0.1-0.3) due to value fluctuations.**Conclusion**: Quantitative analysis of ICR findings with common approaches showed that lesion etiology (i.e., malignant, polyp, or benign) cannot be differentiated by SUV_{max} or SUV_{mean} alone, nor can any useful cutoff value be set. MVP_{mean} might indicate distinctions better by incorporating lesion extent (MAV), but also lacks generally distinctive levels. Variations with different segmentations and PVC contribute to estimate variability, but affected overall relations less. It remains to be assessed whether more optimal data analysis methods and corrections can yield measures, e.g. $MVP_{mean, PVC}$, that better reflect the disease severity and extent than SUV_{max} values.

OP062

18F-FDG PET/CT versus CT evaluation of treatment response in patients with metastatic colorectal cancer receiving chemotherapy with a monoclonal antibody (bevacizumab or cetuximab)

Z. Nemeth[1], Z. Lengyel[2], K. Boér[1], E. Hitre[3], K. Borbély[3]; [1]Szent Margit Hospital, Budapest, HUNGARY, [2]Pozitron-Diagnosztika Kft, Budapest, HUNGARY, [3]National Institute of Oncology, Budapest, HUNGARY.

The study aim was to compare the effectiveness of evaluation of tumour response by positron emission tomography with 18F-fluorodeoxyglucose (18F-FDG PET/CT) and computed tomography (CT scan) in patients with metastatic colorectal cancer receiving combination treatment with chemotherapy and cetuximab or bevacizumab. A total of eleven patients who were candidate first line systemic treatment for metastatic colorectal cancer were enrolled in our study from April to

November 2014. All patients (pts) were evaluated by both 18F-FDG PET/CT and CT scan before and after systemic treatment. 18F-FDG PET/CT evaluation was performed after the second treatment, while the CT scan after the third therapy in every case. Systemic treatment consisted of chemotherapy with 5-fluorouracil, leucovorin, irinotecan (FOLFIRI) in combination with a monoclonal antibody bevacizumab or cetuximab (FOLFIRI+cetuximab: 3 pts and FOLFIRI+ bevacizumab: 8 pts). The primary tumours were histologically proven and all patients had at least one > 2 cm liver metastasis on axial imaging (CT). The maximum standardized uptake value (SUVmax) was measured at baseline and after chemotherapy. The relative FDG uptake changes in liver metastases were calculated (dSUV) as well. Our results were evaluated by European Organisation for Research and Treatment of Cancer (EORTC) FDG response criteria. A total of eleven patients were eligible for response evaluation. Regarding PET/CT with EORTC criteria 8 pts. (72.7%) had partial metabolic response (PMR), 3 pts. (27.3%) had progressive (27.3%) disease (PMD). Patient were classified in two by two tables according to RECIST responders (CR, PR, SD), non responders (PD) based on CT scans, ad classified based on SUVmax responders (> 25% decrease from baseline) and non-responders (< 25% decrease from baseline). Results showed an almost 100% match between the two classification methods (RECIST, EORCT criteria). SUVmax predicted all eight RECIST-responders correctly the only mismatch occured to the fact that progressive disease was not recognised by CT scan, but was reported by PET/CT scan. As regards CT scans there were no significant changes in those 8 pts. who had PMR at PET/CT assessment and in these cases CT showed stable disease. In one case a new lesion was detected only by PET/CT. Based on our preliminary results morphological and metabolic imaging indicates in some cases a differential therapeutic decisions in metastatic colorectal cancer. Moreover the change of SUVmax appears to be a usefull tool for evaluating tumour response. The patient recruitement is open, more data is being collected.

OP063

Comparison of 18F-FDG PET-CT to conventional CT imaging in providing optimal pre-treatment staging in patients with incidentally diagnosed gall bladder cancer.

N. Jain, J. Bal, C. Nagpal, B. Rajashekharrao, A. Velumani; Nueclear Healthcare Limited, Delhi, INDIA.

Introduction: After a cholecystectomy, incidental gallbladder cancer (IGC) requires accurate imaging studies to determine the actual extent of the disease to properly tailor subsequent treatment. Aim: To compare 18F-fluorodeoxyglucose positron emission tomography-computed tomography (18FDG PET-CT) to conventional imaging (CT Abdomen and Chest) to provide optimal pre-treatment staging in patients with IGC. Patients and Methods: Between January 2014 and April 2015, all patients with IGC and at least T1b stage on histopathology underwent 18F-FDG whole body PET-CT. The PET/CT findings were grouped as locoregional disease (operable) and disseminated disease (inoperable). Results of PET/CT were compared with conventional CT imaging. Results: The series included 41 patients, 32 women and 9 men, with a median age of 50 years (range 35-72 years). The Whole body PET CT imaging was performed at a median time of 6 weeks after cholecystectomy (range 4-24 weeks). 18FDG PET-CT findings were negative in 10 patients and positive in 31 patients. Of these 31 patients 7 were with localized potentially resectable disease (PRD) and 24 with disseminated disease (inoperable). Conventional CT imaging observations were negative in 21 patients and positive in 20 patients. Amongst these 20 patients, 3 with localized potentially resectable disease (PRD) and 17 were with disseminated disease. In comparison to CT, PET CT changed management in additional 31.7% cases and thus was superior to conventional imaging ($p=0.02$, $p<0.05$). PET CT also identified more number of lesions in cases with disseminated disease. Conclusions: For patients presenting with stage T1b or greater IGC, the use of 18FDG PET-CT imaging will help reduce the number of patients undergoing non-therapeutic re-exploration and avoid radical surgeries thus tailoring subsequent disease management.

Variation in haplotypes of the norepinephrine transporter is not associated with sympathetic activity as measured by cardiac 123I-mIBG scintigraphy

D. O. Verschure[1,2], F. Baas[1], B. L. F. van Eck - Smit[1], G. A. Somsen[3], H. J. Verberne[1]; [1]Academic Medical Center, Amsterdam, NETHERLANDS, [2]Medisch Centrum Alkmaar, Alkmaar, NETHERLANDS, [3]Cardiology Centers of the Netherlands, Amsterdam, Amsterdam, NETHERLANDS.

Aim^{123}I-*meta*-iodobenzylguanidine (^{123}I-*m*IBG) scintigraphy has been extensively validated and clinically used to evaluate cardiac sympathetic function in cardiac diseases. The semi-quantitative outcome (i.e. heart mediastinal ratio (H/M)) is an independent prognostic parameter in patients with chronic heart failure (CHF). ^{123}I-*m*IBG is a radiolabelled norepinephrine (NE) analog that has the same presynaptic uptake, storage and release mechanism as NE. The norepinephrine transporter (NET), encoded by the solute carrier family 6 (SLC6A2), is responsible

for reuptake of NE into presynaptic nerve terminals and is a regulator of norepinephrine homeostasis. It has been demonstrate that polymorphism of SLC6A2 correlates with blood pressure, but it is unknown if polymorphism of SLC6A2 influence the H/M. Therefore we investigated if SLC6A2 polymorphism influences ^{123}I-*m*IBG results. Materials and Methods: Forty-nine adults with CHF (age 66.5±8.1 years, LVEF 22,3±6.4 and functional class NYHA 2,3±0.4) referred for ^{123}I-*m*IBG scintigraphy were enrolled. 15 minutes (early H/M) and 4 hours (late H/M) after administration of 185 MBq ^{123}I-*m*IBG anterior planar thoracic images were acquired with medium energy collimators. H/M was calculated based on the mean count densities from the manually drawn regions of interest (ROI) over the left ventricle and a predefined fixed ROI placed in the upper mediastinum. DNA of the subjects was extracted from whole-blood samples. Twelve exons of the SLC6A2 gene were analysed.Results The mean early H/M was 2.10±0.39, late H/M 1.81±0.39 and WO 13.7±11.2. Genotyping of the SLC6A2 gene resulted in 6 different genotypes. Between the 2 largest haplotype groups C-T-C-A-T (n=22) vs. C-T-C-A/G-C-G/T (n=18) there was only a significant difference in early H/M (respectively 2.07±0.30 and 2.11 ±0.50, $p = 0.027$). However, multivariate regression analyse using haplotype, LVEF and NYHA class possible explanatory factors, showed only LVEF as an independent predictor of early H/M (adjusted $R^2 = 0.063$, $p = 0.05$). Increased H/M was associated with increased LVEF. For late H/M similar results were obtained where only the LVEF was an independent predictor (adjusted $R^2 = 0.116$, $p = 0.01$). For WO the LVEF and NHYA were independent predictors (adjusted $R^2 = 0.105$, $p = 0.03$). Conclusion: This is the first study that investigated the association between NET polymorphism and cardiac ^{123}I-*m*IBG scintigraphically derived parameters. Despite a small difference in early H/M between the two most common haplotypes, variation in NET haplotype could not explain a significant part of the variation in the ^{123}I-*m*IBG scintigraphically derived parameters.

OP065

Effect of standardization of I-123 MIBG heart-to-mediastinum ratio on the prognostic threshold: application to multicenter database of chronic heart failure

K. Nakajima[1], K. Okuda[2], S. Matsuo[1], T. Nakata[3], S. Kinuya[1]; [1]Kanazawa University Hospital, Kanazawa, JAPAN, [2]Kanazawa Medical University, Uchinada, JAPAN, [3]Hakodate Gryoukaku Hospital, Hakodate, JAPAN.

Purpose. As I-123 metaiodobenzulguanidine (MIBG) has been used for the assessment of prognosis in patients with chronic heart failure (CHF), we have proposed to unify the MIBG heart-to-mediastinum ratio (HMR) to overcome differences in camera-collimator systems. The aim of this study was to evaluate the effect of the standardization on prognostic variables and thresholds for mortality risks. Methods. A total of 225 phantom experiments were performed in 84 hospitals to determine conversion coefficients (K) to the mathematically calculated reference values. For example, the K value of low-energy high-resolution (LEHR) collimator was 0.55, LE general purpose (GP) 0.65, and medium-energy (ME) GP 0.88. Using the collimator-specific K values, all HMRs could be standardized to those of the commonest ME types (ME88). Japanese pooled databases (n=933) from 6 cohort studies, in which at least 5-year prognosis was known, was used for validation. Mean age was 61±13 years, time of follow-up 7.7 ±4.3 years (range 0.08-14.6 years), and ejection fraction 36±13%. Late HMR in the anterior image was used for the analysis in this study. Cardiac death due to pump-failure, acute myocardial infarction and sudden cardiac death was used as a single endpoint. Since 4 hospitals used LEGP and 2 used LEHR collimators, they were unified to HMRs comparable to the ME88 condition. Multivariate analysis and receiver operating curve analysis were applied to compare the original and standardized HMRs. The optimal thresholds for predicting cardiac death were also determined. Results. The original mean HMR of 1.71±0.33 (95% range 1.18-2.41) increased to 2.00±0.44 (95% range 1.25-3.01) as the standardized HMR. The best cutoff values for predicting cardiac death was HMR=1.66 (ROC AUC=0.694) and 1.89 (ROC AUC=0.698) for the original and standardized HMRs, respectively. Multivariate proportional hazard analysis for all the follow-up period selected the same 5 variables of age, male sex, left ventricular ejection fraction, NYHA functional class and MIBG late HMR. Chi-square values of the logistic analysis for the 5-year survival and death using the same variables were 164.9 (ROC AUC 0.780) and 167.2 (ROC AUC 0.781) for original and standardized HMR groups, respectively ($p<0.0001$ for both). Conclusion. Using the calibration phantom method to unify HMRs, all HMRs were successfully converted to the ME88 condition. An optimal threshold for stratifying prognosis became increased (HMR=1.9) with keeping the statistical power to precisely predict cardiac death. The standardization method could further effectively function when both LE and ME collimators are used in a multicenter study.

OP066

Proposal for a standardized method to evaluate 123I-MIBG SPECT in HF patients: importance in decision making of ICD implantation.

V. Frantellizzi, A. Farcomeni, P. Scarpato, G. A. Follacchio, S. Sollaku, N. Salvi, P. Scarparo, M. Liberatore, F. Monteleone, F. Fedele, G. De Vincentis; Sapienza University of Rome, Rome, ITALY.

Patients (pts) with Heart Failure (HF) have high risk of fatal

malignant ventricular arrhythmias. Implantable cardioverter-defibrillator (ICD) is the therapy of choice but ICD implant should be reserved to high risk pts, considering also inappropriate shocks and costs. Aim of the study was to assess if 123I-MIBG scan is useful in decision making for ICD implantation. 170 pts were prospectively evaluated in term of occurrence of arrhythmic events (AE) with mean 19,7 month follow up. The average value of left ventricular ejection fraction (LVEF) was 31,1% +/- 9,4% and among these 69 had idiopathic disease and 101 had post-ischemic disease. At 20 and 240 minutes after MIBG administration, planar and SPECT cardiac images were obtained. Planar images were analyzed as Early and Late Heart-to-Mediastinum (HM) ratio and Washout Rate (WR). SPECT studies were processed with Myovation software (GE Healthcare) and row data for each of 17 segments of a standard polar map were obtained. Using a 5-point visual scoring model , data were semi-quantified and Late Summed Scores (LSS) was obtained. We evaluated area under the ROC curve (AUC) for each diagnostic test and thresholds by means of sensitivity and specificity. Optimal thresholds were chosen by Youden's index. Optimal weights for separate segments were estimated by means of logistic regression, with zero weights fixed by minimization of the Akaike information criterion through forward selection. The HM ratio value of 1.6 showed a 0.64 sensitivity (SE) and 0.415 specificity (SP), whereas a 1,4 cut-off value showed 0.588 SE and 0.809 SP. When examining the WR we obtained for a cut-off value of 20% , 91% SE and 28% SP. More accurate results were obtained with a reference cut-off of 30% , with 73% SE and 53% SP. Taking into account LSS, using a cut off value of 26 we obtained 0.795 SE and 0.274 SP, whereas a cut off value of 43 had a SE of 0.625 and a SP of 0.804. Has, in our opinion, to be underlined how studies conducted with SPECT technique generally have provided very interesting results in the clinical setting, but did not provide technical details on how to achieve and interpret the parameters obtained. In our patients series, the best result in terms of accuracy in predicting AE was achieved by LSS scoring, in spite of a number of criticisms and doubts about the real usefulness and reproducibility of SPECT data by several authors.

OP067

Role of Myocardial Perfusion, Sympathetic Denervation, and Scar Size in Predicting Inducibility of Ventricular Arrhythmia in Ischemic Cardiomyopathy

M. T. Rijnierse, C. P. Allaart, S. De Haan, H. J. Harms, M. C. Huisman, A. M. Beek, A. A. Lammertsma, A. C. Van Rossum, P. Knaapen; VU University Medical Center, Amsterdam, NETHERLANDS.

Introduction: Myocardial perfusion, scar size, sympathetic denervation and innervation-perfusion mismatch, obtained from positron emission tomography (PET) and late gadolinium enhanced cardiovascular magnetic resonance imaging (LGE-CMR), may all contribute to enhanced risk prediction of ventricular arrhythmias (VA). There may, however, be overlap between some of these risk markers, as they are based on similar pathophysiology. The aim of this study was to assess the role of PET and LGE-CMR derived risk markers in predicting VA inducibility in the same patient population.Methods: 52 patients (66 ± 9 years, 90% male, LVEF 29 ± 6%) with ischemic cardiomyopathy and left ventricular ejection fraction (LVEF) ≤35% who were referred for primary prevention implantable cardioverter-defibrillator (ICD) implantation were included. LGE-CMR was performed to assess LV volumes, function, and scar size. [^{15}O]H_2O PET and [^{11}C]hydroxyephedrine PET were performed to assess both resting and hyperemic myocardial blood flow (MBF), and sympathetic innervation. Innervation and perfusion defect size, and innervation-perfusion mismatch size were calculated. After ICD implantation, an electrophysiological study (EPS) was performed and was considered positive in case of sustained VA.Results: Patients with positive EPS (n=25) showed more severely impaired hyperemic MBF (1.36 ± 0.39 vs. 1.71 ± 0.39 mL min^{-1} g^{-1}, *P*=0.003), larger sympathetic denervation size (28 ± 12 vs. 21 ± 13%, *P*=0.048), and tended to have larger scar size (24 ± 13 vs. 18 ± 9 g, *P*=0.07) and perfusion defect size (22 ± 13 vs. 15 ± 11%, *P*=0.06) compared with EPS negative patients (n=27). No differences were observed in LV volumes, LVEF, and innervation-perfusion mismatch size. Multivariable analysis revealed that impaired hyperemic MBF was the single best independent predictor for VA inducibility (OR 0.78, 95% CI 0.65-0.94, *P*=0.007). A combination of risk markers did not yield incremental predictive value over hyperemic MBF alone.Conclusion: Of all previously validated approaches to evaluate the arrhythmic substrate, impaired hyperemic MBF was the only independent predictor of VA inducibility. Moreover, a combined approach of different imaging variables did not have incremental value. These results suggest that quantitative PET perfusion imaging may be promising in risk prediction of VA.

OP068

Prognostic value of myocardial I-123 metaiodobenzylguanidine imaging in patients with atrial fibrillation

Y. Saushkina[1], Y. Lishmanov[1,2], I. Kisteneva[1], S. Popov[1]; [1]RI Cardiology, Tomsk, RUSSIAN FEDERATION, [2]National Research Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION.

Purpose. The problem of diagnostic and treatment of cardiac arrhythmias is one of the most actual in modern medicine. To date, the mechanisms underlying the majority of cardiac arrhythmias are unclear. The disturbance of sympathetic innervation of the heart may be the cause of atrial fibrillation and reason of myocardial dysfunction of the left ventricle. In the 1950s the relationship between the occurrence of AF and the autonomic nervous system has been described. Cardiac autonomic nervous system have been shown to play an important role in the initiation, persistence and termination of AF. In addition, there is actual a question evaluate the effectiveness of the treatment of this arrhythmia. Thus, the purpose of this study was to detect the correlations between the cardiac autonomic innervation and the clinical course of AF after radiofrequency catheter ablation (RFCA). Methods. In this study were enrolled 15 patients with essential hypertension (EH) (the duration of EH was 5-20 years) and persistent AF. All patients underwent single-photon emission computer tomography (SPECT) with I-123 metaiodobenzylguanidine (123I-MIBG) to evaluate cardiac sympathetic nervous system activity before and 12 months after RFCA. SPECT with 123I-MIBG was performed at 20 min (early phase) and 4 h (delayed phase) after intravenous injection. The early and delayed heart-to-mediastinum ratio (HMR) and the washout rate (WR) were performed. Local denervation was evaluated on polar map images using the 17-segment model of left ventricle (LV). Results. A year later after RFCA in 7 patients arrhythmia paroxysms were not observed without antiarrhythmic therapy (AAT). Atrial fibrillation with frequency up to 1 times per month was observed in four patients with AAT. One patient had a repeat RFCA. In all patients the early HMR and delayed HMR was significantly higher vs baseline (1,58±0,15 vs 1,91±0,20; $p<0,05$ and 1,69 ±0,22 vs 1,96±0,42; $p<0,05$). There was no correlation between 123I-MIBG parameters and the duration of EH, the duration of AF and the frequency of AF episodes. However, the delayed HMR before RFCA was strongly correlated with the presence of arrhythmia recurrence a year later after RFCA ($r=-0,878$, $p=0.001$). Also we conducted ROC-analysis and identified the main scintigraphic predictors of the effectiveness of interventional treatment of atrial fibrillation. The most significant indicator in predicting the efficacy of RFCA was delayed HMR=1,7 (AUC=0,99; p=0,0001; sensitivity - 100%; specificity - 71%). Conclusions. Thus, delayed heart-to-mediastinum ratio may be an independent scintigraphic predictor of the effectiveness of interventional treatment of atrial fibrillation.

OP069
Cardiac sympathetic activity in 22q11 deletion syndrome

D. O. Verschure[1,2], E. Boot[1,3], T. A. van Amelsvoort[4], J. Booij[1], B. L. F. van Eck - Smit[1], G. A. Somsen[5], H. J. Verberne[1]; [1]Academic Medical Center, Amsterdam, NETHERLANDS, [2]Medisch Centrum Alkmaar, Alkmaar, NETHERLANDS, [3]The Dalglish Family Hearts and Minds Clinic for Adults with 22q11.2 Deletion Syndrome, Toronto, ON, CANADA, [4]University of Maastricht, Maastricht, NETHERLANDS, [5]Cardiology Centers of the Netherlands, Amsterdam, NETHERLANDS.

Aim: 22q11 Deletion syndrome (22q11DS) is a relatively common genetic condition caused by a microdeletion on the long arm of chromosome 22. The deleted region spans more than 40 genes, one of which is the gene that encodes for the enzyme catechol-O-methyl-transferase (COMT). COMT enzyme is involved in the degradation of catecholamines, including norepinephrine (NE). Indeed, reduced COMT enzyme activity and impaired catecholamine turnover have been reported in 22q11DS.Clinically, adults with 22q11DS are at increased risk for sudden unexpected death. Although the causes are likely multifactorial, increased cardiac sympathetic activity with subsequent fatal arrhythmia, due to increased levels of NE, should be considered as a possible mechanism predisposing to premature death in 22q11DS. The purpose of this study was, therefore, to determine whether cardiac sympathetic activity is increased in adults with 22q11DS compared to healthy controls. Materials and Methods: All study participants underwent 123I-mIBG scintigraphy. Planar 123I-mIBG images were analysed by one experienced observer blinded to patient data. Heart-to-mediastinum ratios (H/M) were calculated from the 123I-mIBG images using a region-of-interest over the heart and the upper part of the mediastinum fifteen minutes (early images) and 4 hours (late images) after administration of 123I-mIBG intravenously. Washout (WO), as an indicator or adrenergic drive, was calculated as a ratio of early and late H/M.ResultsFive adults with 22q11DS (mean age 28.6 ±4.8 years) without any congenital heart disease and five age- and sex-matched healthy controls (mean age 28.0±7.9 years) were enrolled. There were 3 males and 2 females in both groups. There were no significant differences in early and late H/M between the 22q11DS and the control group. However, there was a significant difference in WO between the 22q11DS and the control group (-4.92±2.8 and -10.44±7.2, respectively; p=0.027). Conclusion: This preliminary study for the first time suggests increased adrenergic drive in adults with 22q11DS using 123I-mIBG scintigraphy. This

increased adrenergic drive might explain one possible mechanism predisposing to premature death in 22q11DS.

OP070

Assessment of right ventricular sympathetic dysfunction in patients with Arrhythmogenic Right Ventricular Cardiomyopathy using 123I-Metaiodbenzylguanidin

A. Todica[1], J. Siebermair[2], J. Schiller[1], M. Zacherl[1], W. Fendler[1], P. Bartenstein[1], R. Wakili[2], M. Hacker[3], S. Lehner[1]; [1]Department of Nuclear Medicine - University of Munich, Munich, GERMANY, [2]Medical Department I - University of Munich, Munich, GERMANY, [3]Division of Nuclear Medicine - Medical University Vienna, Vienna, AUSTRIA.

Aim: Arrhythmogenic right ventricular cardiomyopathy (ARVC) is a mainly inherited heart-muscle disease, which is characterized by a progressive replacement of contractile heart muscle by fibrotic and fat tissue primarily in the right ventricle, ultimately resulting in heart failure. The regional reduction of left ventricular myocardial 123I-MIBG-uptake is associated with higher risk of future recurrent life-threatening events in patients with ARVC. Therefore, we prospectively evaluated the sympathetic function using 123I-MIBG SPECT/CT in patients diagnosed with ARVC and in patients with idiopathic ventricular fibrillation (IVF). The objective of this study was to institute a novel approach by using the additional morphological information from the low-dose CT. Methods: Sympathetic innervation of the heart was assessed using 123I-MIBG SPECT/low-dose CT in 13 patients diagnosed with ARVC according to the modified task force criterions, and 10 patients diagnosed with IVF. Late planar H/M ratio was calculated for both groups. The 123I-MIBG uptake in the left (LV/M) and right ventricle (RV/M) was evaluated separately based on the morphological information available from the CT scan and set in relation to the uptake in the mediastinum. Results: The mean planar H/M ratio in the ARVC group was slightly lower as compared to the IVF group but did not reach statistical significance (1.5±03 vs. 1.7±0.2, p=0.068). The optimal cut-off value to discriminate between ARVC and IVF was 1.66 with a sensitivity of 75%, a specificity of 60% and an AUC of 0.73. There was a significant difference between the ARVC and the IVF group for the LV/M ratio (3.2±0.5 vs. 3.9±0.8, p=0.014). The ideal cut-off value was 3.41 (sensitivity 77%, specificity 80%, AUC 0.78). The RV/M ratio was able to distinguish best between ARVC and IVF resulting in a higher significance (1.6 ±0.3 vs. 2.0±0.2, p=0.001). Hereby the best cut-off value was 1.88 (sensitivity 88%, specificity 90%, AUC 0.93). Conclusion: The separate assessment of the left and right ventricle could be reliably performed with the help of the low-dose CT. The RV/M ratio was significantly lower in patients with diagnosed ARVC and the RV/M ratio could distinguish with the highest sensitivity and specificity between ARVC patients and our reference collective.

OP071

Sleep-disordered breathing is associated with impaired cardiac sympathetic innervation and predict prognosis in patients with heart failure

T. Pellegrino[1], S. Paolillo[2], V. Piscopo[2], A. Boemio[2], R. Carotenuto[2], B. Russo[2], S. Pellegrino[2], G. De Matteis[2], P. Perrone Filardi[2], A. Cuocolo[2]; [1]Institute of Biostructures and Bioimages, Naples, ITALY, [2]University of Naples - Federico II, Naples, ITALY.

Background: Unfavorable effects of sleep-disordered breathing (SDB) in heart failure (HF) are mainly mediated by impaired sympathetic activity. However, few data are available on SDB and cardiac adrenergic impairment evaluated at myocardial level. The aim of the present study was to assess the relationship between SDB, cardiac sympathetic innervation and prognosis in HF patients. Methods: Ninety-four patients (66.1±9.8 years) with systolic HF (median left ventricular ejection fraction 32±7%) underwent nocturnal cardiorespiratory monitoring to assess presence and type of SDB by Apnea/Hypopnea Index (AHI), and 123I-MIBG myocardial scintigraphy to calculate heart-to-mediastinum (H/M) ratios and 123I-MIBG washout rate. Patients were prospectively followed for 29±18 months for the combined endpoint of cardiovascular death and HF hospitalization. Results: Of 94 patients, 72 (77%) showed SDB and, compared to non-SDB, had significantly reduced early (1.67±0.22 vs. 1.77 ±0.13; $p<0.02$) and late (1.50±0.22 vs. 1.61±0.23; $p<0.04$) H/M ratios. At multiple linear regression analysis, early and late H/M ratios remained independent predictors of AHI ($\beta=-0.749$; $p<0.001$; $\beta=-0.830$; $p=0.001$, respectively). Similarly, AHI was the only predictor of early ($\beta=-0.643$; $p<0.001$) and late ($\beta=-0.453$; $p<0.002$) H/M ratios. Patients with AHI above the median showed significantly higher event rates and worse survival compared to patients with AHI below the median (35% vs. 9%, respectively; $p<0.01$). Similarly, patients with moderate to severe disorder showed significantly increased incidence of the combined endpoint and worse survival compared to patients with mild or no disorder (35% vs. 11.7%; $p<0.01$). Adding SDB variables to the already known prognostic role of 123I-MIBG imaging, we observed an incremental prognostic discrimination with the

worst survival in patients with both SDB and H/M impairment. Conclusions: Patients with systolic HF and SDB show more impaired cardiac adrenergic innervation and more adverse prognosis compared to HF patients without SDB.

Aim: MIP-1404 is a technetium-99m labeled small molecule to image PSMA expression in prostate cancer. The objective of this analysis was to explore the relationship between MIP-1404 uptake in the prostate gland and the incidence of upgrading and downgrading of prostate needle biopsies following radical prostatectomy (RP) in the phase 2 clinical trial MIP-1404-201 (NCT01667536). Materials / Methods: Prostate needle biopsy Gleason scores recorded in case report forms of 104 patients prior to surgery were compared to the final histopathologic Gleason score of the RP specimen, assessed by the site pathologist, to determine the rate of upgrading and downgrading in evaluable patients with pre-surgical biopsy and post-surgery pathology results. ^{99m}Tc-MIP-1404 SPECT/CT of the pelvis was acquired prior to surgery. Quantitative results of MIP-1404 uptake were obtained by calculating the maximal tumor to background ratio (TBR) for the prostate gland of each patient. A one-sided Student's t-test was performed to test for significant increase in TBR between patients with upgraded or downgraded final histopathologic Gleason score ≤7 and >7. Results: 31% (25/81) of evaluable patients had their biopsy Gleason score upgraded to >7 or downgraded to ≤7 by histopathologic assessment of the prostatectomy specimen. 79% (11/14) of patients upgraded to a Gleason score > 7 including one downgraded (Gleason 9 to 8) demonstrated high MIP-1404 lesion uptake (TBR >30:1) with a mean TBR of 47:1 [95% CI (30-63:1)]. 91% (10/11) of patients downgraded to Gleason score ≤7 had significantly (P<0.001) lower lesion uptake (TBR <30:1) with a mean TBR of 16:1 [95% CI (10-22:1)]. Conclusion: MIP-1404 uptake in the prostate gland is significantly higher in prostate cancer patients upgraded at RP from those who are downgraded at RP. MIP-1404 may be useful to indicate if a needle biopsy has under- or overestimated the severity of disease.

OP084
Differences in biodistribution of Lu-177-DKFZ-PSMA-617 and Ga-68-DKFZ-PSMA-11 in the same patient group

O. E. SAHIN[1], J. NEMATYAZAR[1], B. RAZAVI[1], N. YEYIN[1], A. AYGUN[1], M. OCAK[2], E. DEMIRCI[3], L. KABASAKAL[1]; [1]Istanbul University,Cerrahpasa Medical Faculty,Department of Nuclear Medicine, İstanbul, TURKEY, [2]Istanbul University,Pharmacy Faculty,Department of Pharmaceutical Technology, İstanbul, TURKEY, [3]Sisli Etfal Training and Research Hospital,Department of Nuclear Medicine, İstanbul, TURKEY.

Aim: PSMA is an excellent target for prostate cancer imaging and therapy using Ga-68 and Lu-177 labeled ligands. Human biodistribution studies of Ga-68-PSMA ligand have demonstrated that highest uptake of radiotracer is observed on kidneys and salivary glands and moderate uptake in lacrimal glands, liver and spleen. However, Lu-177-PSMA-ligand is a different compound and there is no information about its biodistribution. Therefore the aim of the study was to evaluate the biodistribution of these two compounds. Material and Method: For this purpose, 17 patients (mean age 68.8±6.7 years) who had PSMA PET/CT imaging and who underwent Lu-177-PSMA therapy were included. PSMA PET imaging was not longer then 1 month at the time of therapy. SUVmax values of parotid glands, kidneys, liver, spleen and primary

tumour (n=6), metastatic lymph nodes (n=8) and bone metastases (n=9) were obtained from PET images. From the SPECT/CT images obtained 24 h after Lu-177-PSMA administration ROIs were drawn over the same areas and background corrected maximum counts are calculated. Results: Highest uptake is observed in kidneys (45.0±18.9) followed by lymph nodes (23.2±24.8), bone metastases (15.9±6.0), primary tumor (12.8±15.9), parotid gland (12.2±3.1) and lowest in lacrimal glands (7.5±4.3) in PSMA PET images. The biodistribution of Lu-177-PSMA was completely different giving the highest uptake in parotid glands (678.7±352.2) followed by bone metastases (651.7±498.8) lymph nodes (561.3±322.8), lacrimal glands (342.4±231.0) kidneys (249.0±146.8) and primary tumor (102.5±78.2). Conclusion: It seems that biodistribution of Lu-177-PSMA is different then Ga-68-PSMA and highest radiation absorbed doses are given to parotid gland and to the metastatic tissues during the therapy of Lu-177-PSMA. Kidneys are getting significantly lower radiation doses as compared to that of Ga-68-PSMA due to lower uptake.

OP085

(68)Ga-labelled PSMA in prostate cancer: its diagnostic value in patients with biochemical recurrence of prostate cancer

S. Vöö, A. van Kroonenburgh, F. M. Mottaghy; Maastricht University Medical Center, Maastricht, NETHERLANDS.

Background: There is an ongoing need for an accurate imaging modality which can be used for staging, metastatic evaluation, predicting biologic aggressiveness, and investigating recurrent disease in prostate cancer. Prostate specific membrane antigen (PSMA) displays an increased expression in prostate tumor cells and is regarded as an ideal target for prostate cancer. Its biodistribution is favourable in comparison to choline or acetate. Recently, a new anti-PSMA-HBED ligand [(68)Ga-PSMA] has been introduced for PET imaging of prostate cancer. Goal. The aim of this evaluation was to analyse the diagnostic value of (68)Ga-PSMA PET/CT in patients with suspected recurrent prostate cancer and a possible association between different clinical variables and the imaging results. Methodology. We performed a retrospective analysis on 30 consecutive patients (median age 68 years) with suspected biochemical recurrence of prostate cancer who underwent (68)Ga-PSMA PET/CT between January 2013-December 2014. Other clinical factors such as prostate-specific antigen (PSA) level, PSA doubling time (PSA-DT), Gleason score (GSC), age, and amount of injected tracer were evaluated in correlation with the imaging results. Furthermore, multifocal prostate biopsies or clinical follow-up were performed in all patients following the (68)Ga-PSMA PET/CT. Results. In 83.3% of the patients at least one lesion indicative of prostate cancer recurrence was detected. A total of 45 focal prostatic lesions were considered positive on (68)Ga-PSMA PET with an average maximum standardized uptake value (SUVmax) of 12 ± 8 (1.1-25), compared to a low background SUV (median SUV 0.7). All PET-positive lesions were confirmed as true-positive on histology and/or clinical follow-up. However, of all prostate biopsy samples taken for verification, 3 samples proved to be positive on histology but false-negative on PET (Gleason 4). Tumor detection was positively associated with the PSA levels (>2.5 ng/ml). Other clinical parameters, such as GSC, PSA-DT, age, and dose of injected tracer, showed no association with the PSMA PET findings. A lesion-based analysis revealed a sensitivity, specificity, negative predictive value (NPV), and positive predictive value (PPV) of 93%, 100%, 92%, and 100%, respectively. A patient-based analysis revealed a sensitivity of 96%. Conclusion. (68)Ga-PSMA PET/CT shows a high sensitivity and, importantly, a high specificity in detecting prostate cancer, even in patients with low PSA levels. Therefore, PSMA(-HBED) PET/CT is a promising imaging approach that could guide the therapy management in patients with suspected recurrence of the disease.

OP086

Pelvic Dynamic Imaging with Pixel-Based Analysis of Ga-68 PSMA PET/CT

E. Hsiao, G. P. Schembri, D. L. Bailey, E. A. Bailey, P. J. Roach; Royal North Shore Hospital, St Leonards, AUSTRALIA.

Aims:Ga-68 PSMA is a relatively new PET tracer for prostate carcinoma. Little in vivo data are available in humans on its uptake kinetics in normal and pathologic sites. The study aims to assess the uptake rates in normal tissues and to investigate the timing of tracer uptake in pathologic sites compared to physiologic bladder or ureteric activity.Materials and Methods:Ten patients referred for PSMA PET/CT (3 for staging and 7 for biochemical recurrence) underwent a 30-minute dynamic scan of the pelvis on a Siemens Biograph mCT following administration of 127-158MBq of Ga-68 PSMA (HBED) as well as a 1-hr post-injection whole body scan. Time-activity data were obtained and Patlak-Rutland analysis was performed using in- house software. K_i (influx rate constant) and V_d (volume of distribution) maps were generated from the regression curves fitted pixel-by-pixel. Uptake rate of PSMA avid lesions and normal sites were assessed.Results:Five patients had local PSMA-avid disease, while 7 pathologic nodes were evident in 2 patients and 4 bone sites of uptake were evident in 3 patients. Two patients had no

PSMA-avid disease in the field of view. Normal sites for correlation were defined as the sites without focal PSMA uptake on conventional 1-hr delay imaging. There were 9 bone sites, 4 prostate sites and 7 pelvic nodes. Time-activity curves were so far obtained in 3 patients comparing the pathological sites to ureters and bladders. Conclusion: Both primary and metastatic prostate carcinomas show rapid and early uptake of Ga-68 PSMA within minutes of injection and markedly higher uptake rates compared to normal tissues. The bladder and ureteric activities begin to rise after 15 minutes. Early imaging of PSMA may offer improved depiction of disease burden with less confounding bladder or ureteric activity..

OP087

Cervical lymph node metastases is not an uncommon finding in Ga-68-DKFZ-PSMA-11 PET/CT imaging in patients with prostate cancer

J. Nematyazar[1], O. E. SAHIN[1], B. RAZAVI[1], E. DEMIRCI[2], A. AYGUN[1], M. OCAK[3], C. OBEK[4], A. R. KURAL[5], L. KABASAKAL[1]; [1]Department of Nuclear Medicine, Cerrahpasa Medical Faculty, Istanbul University, Istanbul, TURKEY, [2]Department of Nuclear Medicine, Sisli Etfal Training and Research Hospital, Istanbul, TURKEY, [3]Department of Pharmaceutical Technology, Pharmacy Faculty, Istanbul University, Istanbul, TURKEY, [4]Department of Urology, Cerrahpasa Medical Faculty, Istanbul University, Istanbul, TURKEY, [5]Department of Urology, Acibadem University Medical Faculty, Istanbul, TURKEY.

Aim: Prostate cancer is the most common solid cancer in men and it is the second most common cause of death. The type of therapy in prostate cancer is mainly influenced by the presence of metastases. Recently, it has been shown that PSMA PET imaging with Ga-68 labeled small molecule inhibitors are highly sensitive and specific for detection of prostate cancer and its metastases. Whole body imaging feature of PET imaging makes it possible to detect metastases at unexpected sites of the body. The aim of the present study was to evaluate the distribution of metastatic sites in prostate cancer patients who underwent PSMA PET imaging. Material and method: We retrospectively evaluated the files of patients who underwent Ga-68-PSMA PET imaging in our institution between October 2013 and February 2015. There were 391 PSMA PET imaging studies performed for the indication of staging, restaging and therapy monitoring. Mean age was 66.7 ±8.1 years and mean PSA level was 22.1±69.0 ranging from 0.01 to 700. Results: In PSMA PET imaging there was a positive lesion in 315 (80%) patients. Among these patients, primary tumor was detected in 215 (68%) patients. Bone, lymph node and organ metastases were detected in 117 (37%), 130 (41%) and 15 (5%) patients, respectively. Bone or lymph node metastases were detected in 186 (60%) patients. Among them 54 (30%) patients had only bone and 68 (37 %) patients had only lymph node metastases. In patients who had lymph node metastases 108 (82%) had pelvic, 46 (%35) had abdominal and 22 (17%) had cervical lymph node metastases. Conclusion: The distribution of metastatic sites in PSMA PET imaging suggested that cervical lymph node metastases is not an uncommon finding even with low PSA levels. Also these findings suggested that prostate cancer may have different biological features, some of them may have osteophilic and some of them may have lymphophilic behavior

OP088

Prospective Comparison of the detection rate of 18F-Fluoromethylcholine and 68Ga-PSMA-HBED PET/CT in men with prostate cancer with rising PSA post curative intent therapy, being considered for targeted therapy

J. Morigi[1,2], P. Stricker[3,4], P. van Leeuwen[3,4], R. Tang[2,5], B. Ho[2], Q. Nguyen[3,4], A. Hickey[2], D. Stark[2], A. Young[2], S. Fanti[1], L. Tarlinton[2], L. Emmett[2,5]; [1]Nuclear Medicine OU, Policlinico S.Orsola-Malpighi / University of Bologna, Bologna, ITALY, [2]Department of Diagnostic Imaging, St Vincent's Public Hospital, Sydney, NSW, AUSTRALIA, [3]St Vincent's Prostate Cancer Centre, St Vincent's Clinic, Sydney, NSW, AUSTRALIA, [4]Australian Prostate Cancer Research Centre – New South Wales, The Garvan Institute of Medical Research/The Kinghorn Cancer Centre, Sydney, NSW, AUSTRALIA, [5]University of New South Wales (UNSW), Sydney, NSW, AUSTRALIA.

Aim: In men with prostate cancer (PCa) and biochemical failure following therapy, current imaging techniques have a low detection rate at PSA levels at which targeted salvage therapy is effective. 11C-Choline or 18F-Fluoromethylcholine (FMC), though widely used, have poor sensitivity at low PSA levels. 68Ga-PSMA-HBED (PSMA) has shown promising results in retrospective trials. The aim of this study is to prospectively compare detection rates of PSMA versus FMC PET/CT in men initially managed with either radical prostatectomy (RP) or radiation treatment (RT), being considered for targeted therapy.Methods: A referred sample of men with rising PSA following treatment, eligible for targeted treatment, was prospectively included. Patients on hormonal or chemotherapy treatment were excluded. PSMA, FMC PET/CT and diagnostic CT were

undertaken in all patients sequentially, and assessed by blinded experienced readers. Scan results and management impact change was documented. Results: 38 patients (pts) were enrolled. 34/38 (89%) pts were post-RP, 4/38 (11%) pts were post-RT. 12/38 (32%) pts underwent initial RP and subsequent salvage RT. Mean PSA at imaging was 1.74 ± 2.54 ng/ml. Overall, 68% (26/38) of pts had a positive scan indicating at least one lesion suspicious for PCa recurrence. Of these, 14/26 (54%) were positive on PSMA alone, 42% (11/26) were positive on both FMC and PSMA, 1/26 on FMC alone (false positive on biopsy). Histopathology was available at time of submission for 6 PSMA lesions, all true positive (6/6). Diagnostic CT was inconclusive in all men. With PSA 2.0, 86% PSMA vs. 57% FMC. On lesion-based analysis, PSMA detected more lesions than FMC (59 vs. 29, $p < 0.001$). There was a 63% (24/38) overall management impact, 54% (13/24) due to PSMA imaging alone. The primary limitation is absence of histopathology in some lesions due to small lesion size/accessibility. Conclusion: In patients with rising PSA evaluated for targeted treatment , PSMA demonstrated a significantly higher detection rate at low PSA levels, resulting in a significant overall management impact.

Ac-225-DOTATOC - dose finding for alpha particle emitter based radionuclide therapy of neuroendocrine tumors

C. Kratochwil[1], F. Bruchertseifert[2], F. L. Giesel[1], C. Apostolidis[2], U. Haberkorn[1], A. Morgenstern[2]; [1]University Hospital Heidelberg, Heidelberg, GERMANY, [2]European Commission - Joint Research Centre, Institute for Transuranium Elements, Karlsruhe, GERMANY.

Objectives: There are no established dosimetry tools to predict toxicity of "targeted alpha-therapy" (TAT), yet. We conducted an dose escalation to find the maximum tolerable dose (MDT) of single cycle and fractionation concepts for Ac-225-DOTATOC radionuclide therapy. Methods: According to Declaration of Helsinki's "Unproven interventions in Clinical Practice" we performed 48 treatment cycles in 36 patients with progressive neuroendocrine tumors (NET). After each cycle acute hematotoxicity was documented according to CTCAE criteria. First observations are also available for chronic kidney toxicity as the follow up for the first 17 patients has now reached 2 years. Results: The MTD of a single cycle Ac-225-DOTATOC was considered to be 40 MBq. Multiple fractions were tolerated with 25 MBq every 4 months or 18.5 MBq every 2 months. Cumulative activities of 75 MBq were found tolerable in regard to delayed toxicity. The radiologic treatment response that was observed in some patients is without clear preference of a particular fractionation concept until now. Conclusions: We present a well tolerable treatment protocol for TAT with Ac-225-DOTATOC in NET patients that also demonstrated promising Treatment efficacy in various patients. If TAT provides general advantages in comparison to beta emitter based radionuclide therapy cannot be derived from the available data, yet. Comparative trials are needed in the future.

OP090

Optimal sampling schedule: accurate estimation of time-integrated activity coefficients in peptide receptor radionuclide therapy (PRRT)

C. Maaß[1], J. Sachs[1], D. Hardiansyah[1], P. Kletting[2], F. M. Mottaghy[3], G. Glatting[1]; [1]Medical Radiation Physics/Radiation Protection, Medical Faculty Mannheim, Heidelberg University, Mannheim, GERMANY, [2]Department of Nuclear Medicine, Ulm, GERMANY, [3]Department of Nuclear Medicine, Aachen, GERMANY.

Aim: The aim of this study was (1) to determine population parameter values and using these parameter values (2) to quantify the effect of sampling schedules with differing sizes on the estimation of time-integrated activity coefficients in PRRT with 111In DTPAOC in 15 patients.Materials and Methods: Fifteen patients with proven neuroendocrine tumours (NETs) were investigated. Planar whole-body scans using a double-head γ-camera (ECAM, Siemens, Erlangen, Germany) were performed at 45 min, 4 h, 1, 2 and 3 or 5 d and serum measurements were taken at 5 min, 0.5, 1, 2, 4 h and 1, 2, 3 or 5 d after injection of 111In-DTPAOC [1].A physiologically based pharmacokinetic (PBPK) model [1] was implemented using SAAMII software (version 2.2, The Epsilon Group, Charlottesville, USA). Population parameter values were determined using an iterative two stage (ITS) algorithm.Using both individual and population based parameter values and sampling schedules with different sizes in the model, the relative difference (RD) between actual and estimated time-integrated activity coefficients for tumour, kidneys, liver, spleen, serum and whole body was quantified.Sampling schedules were modified as follows: (1) one and (2) two measurement points (5 and 10 cases/patient) omitted once for each organ and the serum measurements. Mean and standard deviation of the RD were calculated and averaged over all cases and all

patients.Results: Using the individual parameter values the mean RDs were for tumour, kidneys, liver, spleen, serum and whole body (1) (0±4)%, (0±2)%, (3±11)%, (3±9)%, (5 ±14)%, (1±3)% and (2) (13±35)%, (0±2)%, (4±11)%, (3 ±8)%, (4±15)%, (1±3)%.Using the population based parameter values the mean RDs were for tumour, kidney, liver, spleen, serum and whole body (1) (0±1)%, (0±0)%, (0±3)%, (0±1)%, (-1±4)%, (0±1)% and (2) (13±37)%, (0±1)%, (1±2)%, (0 ±1)%, (-1±6)%, (0±2)%.Conclusion: The application of Bayes parameters in physiologically based pharmacokinetic modelling allowed for an accurate estimation of time-integrated activity coefficients even in case less information (measurement data) is available. In this patient group, omitting one measurement point leads only to a small error.Literature1.Kletting P, Müller B, Erentok B, Schmaljohann Jr, Behrendt FF, Reske SN, et al. Differences in predicted and actually absorbed doses in peptide receptor radionuclide therapy. Med Phys. 2012;39(9):5708.

OP091

The intensity of 18FDG uptake is not a surrogate marker of morphological tumor progression in patients with metastatic differentiated thyroid cancer.

M. Terroir, I. Borget, F. Bidault, D. Deandreis, A. Al Ghuzlan, D. Hartl, M. Ricard, A. Berdelou, L. Dercle, J. Lumbroso, E. Baudin, M. Schlumberger, S. Leboulleux; Gustave Roussy, Villejuif, FRANCE.

Aim: In patients with metastatic differentiated thyroid carcinoma (DTC), thyroglobulin doubling time (TgDT) and fluorodeoxyglucose (FDG) uptake as well as age, tumor size and iodine uptake are prognostic factors for survival. High FDG uptake is a poor prognostic factor. Consequently, lesions with high FDG uptake are often considered aggressive and may be monitored and treated with local modalities.The aims of this retrospective single center study were to determine whether the intensity of FDG uptake was correlated to tumor progression or tumor growth rate (TGR) expressed as the percentage of increase in tumor size during a one year-period (TGR) and to TgDT.Materials and methods: Fifty five patients with DTC were included between July 2012 and May 2014 with the following criteria: (i) at least one distant metastasis measuring ≥ 1 cm in diameter (ii) evaluation by FDG-positron emission tomography/computed tomography (PET/CT) performed at our center (iii) at least one CT or another FDG-PET/CT performed more than 3 months after the reference FDG-PET/CT (iv) absence of systemic or local treatment between the two imaging procedures.Results: At the patient level, DTC were papillary (33), follicular (8) or poorly differentiated (14). Forty-seven patients were refractory to radioactive iodine (RAI). Their mean TgDT when available was 101 days with TgDT <1 year in 20 patients and >1 year in 12 patients. The median higher SUV max of each patient was 13.2 (range 3.6-66.2). The two-year survival was 100% for patients with SUV max <5 and 68% for patients with SUV max >5. The TgDT was 258 days for patients with SUV max <5 and 101 days for patients with SUV max >5. At the lesion level, one hundred fifty six metastatic lesions located in the lung (63), neck lymph nodes (28), chest lymph nodes (42), bone (11), liver (2) and other sites (10) were studied. The median size was 16 mm, median SUV max: 8.7; median metabolic volume: 3.7 cm^3. The median one-year TGR by lesion was 16% (range 0->100%). SUV max and metabolic volume of each lesion were not correlated to their one-year TGR (p=0.28 and p=0.77 respectively). SUV max of each lesion was not correlated to tumor size.Conclusion: The intensity of FDG uptake is not correlated to morphological tumor progression assessed by one-year TGR and cannot be used as a surrogate marker of morphological progression.

OP092

Assessment of lesion response in differentiated thyroid cancer patients undergoing radioiodine treatment using 124I PET/CT

R. Wierts[1], B. Brans[1], B. Havekes[1], S. G. E. A. Halders[1], F. M. Mottaghy[1,2], W. Jentzen[3]; [1]Maastricht University Medical Center, Maastricht, NETHERLANDS, [2]University Hospital RWTH Aachen University, Aachen, GERMANY, [3]Klinik für Nuklearmedizin, Universität Duisburg-Essen,, Essen, GERMANY.

Aim: This study assesses the lesion response in patients with differentiated thyroid cancer (DTC) undergoing radioiodine therapy by means of 124I PET/CT, 18F-FDG PET/CT, and/or 131I SPECT(/CT) imaging. Materials and methods: Pretherapeutic 124I PET/CT images of 41 DTC patients undergoing radioiodine therapy were retrospectively analyzed. 124I PET/CT images were acquired 24 and ≥96 hours after oral administration of approximately 28 MBq. Using an automated iterative thresholding algorithm, each lesion was segmented on the PET images to determine the volume and residence time used to predict the therapy-delivered absorbed radiation dose (TAD). The lower volume limit of determinability was 0.15 mL; following a previous study, the minimum TAD was determined for smaller lesions. Lesions were identified as thyroid remnants or metastatic tissue (lymph node, pulmonary, mediastinal, bone). Lesion response was determined based on 124I PET/CT, 18F-FDG PET/CT and/or 131I SPECT(/CT) follow-up images performed in the first year after treatment. A lesion not evident on any of the follow-up images was considered a completely responding lesion; otherwise assigned as an incompletely responding lesion. Significant

differences in TADs and lesion volumes were evaluated by Mann-Whitney U test. Results: Of 161 lesions included, 113 (70.2%) were identified as thyroid remnants and 48 as metastases (29.8%). 69 (61.1%) thyroid remnants and 26 metastases (54.1%) were smaller than 0.15 mL. Complete response was observed for 96 thyroid remnants (85.0%) and 30 metastases (62.5%). For thyroid remnants and metastases, the median TAD of the completely responding group was significantly higher (remnants: 200 Gy, metastases: 62 Gy) than the median TAD of the incompletely responding group (remnants: 54 Gy, metastases: 15 Gy); the significance levels (P) were 0.046 for the thyroid remnants and 0.018 for the metastases. For metastases, the lesion volumes were significantly smaller for the completely responding lesions than that of the incompletely responding lesions (P=0.001) but not for the thyroid remnants (P=0.168). Conclusion: 124I PET/CT-based lesion dosimetry in combination with 18F-FDG PET/CT and/or 131I SPECT(/CT) follow-up images can be used for the assessment of lesion response in DTC patients undergoing RAIT.

OP093

Bone marrow dosimetry assessed with quantitative SPECT/CT is predictive of subacute thrombocytopenia following ^{177}Lu-octreotate PRRT

M. E. Marcotte, M. Del Prete, E. O. Gaudin, F. A. Buteau, P. Després, **J. M. Beauregard**; Université Laval, Quebec City, QC, CANADA.

Aim: Along with the kidney, the bone marrow (BM) is a critical organ in ^{177}Lu-octreotate peptide receptor radionuclide therapy (PRRT). Traditionally, BM dosimetry has been assessed using serial blood sampling, which is cumbersome and also inaccurate when a large tumor burden results in a significant cross-dose to the BM. Quantitative SPECT (QSPECT) can overcome these limitations. Our aim was to correlate QSPECT-derived BM dose estimates with the short-term platelet (PLT) count variation following ^{177}Lu PRRT. Materials and Methods: 29 ^{177}Lu-octreotate cycles (median: 7.4, range: 5.6 to 8.3 GBq) in 8 patients suffering from neuroendocrine tumour were studied. Patients underwent serial QSPECT/CT at 4, 24 and 72 h. Self-dose to the BM was derived from activity concentration sampling using a volume of interest over L4 vertebral body, while the cross-dose to the BM was estimated from total activity retention in the QSPECT field of view. For each individual cycle, the total BM dose was correlated to absolute and relative PLT count variation from baseline (lowest count between 2 and 4 weeks post-PRRT). Results: Median BM dose per cycle was 148 (62 to 370) mGy, and the cross-dose accounted for a median of 7.7 (2.8 to 47.7) % of the total BM dose. Median absolute and relative PLT count variations were -17 (-100 to 64) x10^9/L and -7.5 (-32 to 59) %, respectively. There was a significant, moderate inverse correlation between the absolute or relative PLT variation and BM dose, with Spearman *r* values of -0.47 (*P*=0.01) and -0.39 (*P*=0.04), respectively. Thrombocytopenia occurred following every cycles where >150 mGy were delivered to the BM, and was more pronounced than where <150 mGy were delivered (median of -8 vs. -43 x10^9/L, respectively; *P*=0.005). Conclusion: Our results provide an initial clinical validation of the accuracy of QSPECT-based BM dosimetry, which appears to be predictive of subacute BM toxicity, i.e. transient thrombocytopenia. QPSECT has the potential to become a non-invasive and practical approach for simultaneous tumour, kidney and BM dosimetry in ^{177}Lu radionuclide therapy, hence facilitating the implementation of personalized PRRT.

OP094

Comparison of quantitative ^{177}Lu measurements in European hospitals

A. Fenwick[1], J. Merrett[2,1,3], L. Johansson[1]; [1]National Physical Laboratory, Teddington, UNITED KINGDOM, [2]University of Surrey, Guildford, UNITED KINGDOM, [3]Royal Surrey County Hospital, Guildford, UNITED KINGDOM.

The accuracy of quantitative imaging in SPECT is critical when determining doses delivered during PRRT therapies with ^{177}Lu. In order to determine the measurement capability of a representative subset of hospitals within Europe, a comparison exercise was developed to test both the inter-clinic variability and to assess which methods for activity determination were most effective. An elliptical Jaszczak phantom containing an anthropomorphic insert with lung and bone-equivalent materials and an exterior set of body contour rings was used to compare the ability of leading clinics in the UK, Netherlands, Germany, Sweden, Italy and the Czech Republic. The phantom was used in conjunction with a set of well-characterised, traceable ^{177}Lu sources consisting of an inner hot spherical core surrounded by an outer warm background at an activity concentration ratio of approximately 1:15. The total activity in the spheres ranged from 60-100 MBq at the time of measurement. The sources were designed to mimic a relatively large tumour with homogeneous uptake of ^{177}Lu labelled peptides within a liver which also had partial homogeneous uptake. Although this setup could only be described as partly representative of a real patient, the principles regarding the ability of the camera to recover the activity (although simplified) are largely the same. SPECT/CT Images were taken with both a standard set of acquisition parameters and those used clinically at each site (if different). A total of 6 sources were used in the exercise, all of which were made at NPL and produced in a manner traceable to national standards. The results show that

large deviations were observed at some sites, however, the majority of clinical centres were able to determine the activity to within ±20%. In conclusion, improved calibration protocols should be developed and harmonised in order to improve accuracy and guidance on methods for making standard calibration phantoms should be given at a European level.

Enabling Research on Epilepsy through a New and Efficient Synthesis of [18F]UCB-H, a PET Tracer for the Imaging of SV2A

C. Warnier[1,2], C. Lemaire[1,2], J. Aerts[1,2], J. Mercier[3], A. Plenevaux[1,2], A. Luxen[1,2]; [1]University of Liege, Liege, BELGIUM, [2]Cyclotron Research Centre, Liege, BELGIUM, [3]UCB Pharma, Braine-L'Alleud, BELGIUM.

IntroductionEpilepsy is a neurological condition that affects an estimated 50 million people throughout the world. Although a number of treatments are available for that disease, the cellular mechanisms at the origin of epilepsy remain largely unknown. From that perspective, considerable effort was put into the development of [18F]UCB-H, which recently proved to be a very promising PET tracer for the exploration of neurotransmission processes, and the diseases related to their malfunction, such as epilepsy[1-4]. [18F]UCB-H binds specifically, and with nanomolar affinity to the Synaptic Vesicle Protein 2A (SV2A), which is also the binding site of the anti-epileptic drug Levetiracetam (Keppra®, UCB Pharma). Until now, [18F]UCB-H was only available through a long, multi-step radiosynthesis that is technically complex to implement and affords a limited yield of radiotracer.[5]MethodsIn this work, we present a new short, simple and efficient single-step radiosynthesis of [18F]UCB-H. We successfully synthesized a N-heteroaryliodonium precursor of the radiotracer. The direct labelling of the iodonium using the classical Kryptofix/K18F fluorination method afforded good RCY's of nca[18F]UCB-H (RCY's > 50%). An automation sequence for this straightforward radiosynthesis was therefore developed.ResultsThe fully automated radiosynthesis, from [18F]fluoride trapping on QMA to the end of the automated distribution of the injectable [18F]UCB-H, lasts 60 min and affords 32±2% RCY (n=6, 50<A(StartOfSynthesis)<240 GBq), non-corrected for decay. High specific activities of 500-1000GBq/μmol at the end of the synthesis were obtained, as determined by radio-UPLC analysis. Moreover, data concerning the stability of the precursor, radiochemical & chemical purity of [18F]UCB-H, as well as solvent trace analysis and stability of the tracer in the final formulation, confirm that this production method shall fulfill the standard GMP requirements.ConclusionWe designed a new production method for [18F]UCB-H that is short and easy to implement on any automation system. To the best of our knowledge, this is the first diaryliodonium 18F-labelling that has been adapted for the production of high activites (up to 95GBq) of a radiotracer fit for clinical trials.AcknowledgementsWe gratefully acknowledge the FRS-FNRS (FRIA) for funding this work and UCB Pharma SA Belgium for collaborationReferences[1] Warnock, G. Radiolabeling of proteins using radiofluorinated nitrile oxides

P. Krapf[1,2], **B. D. Zlatopolskiy**[1,2], R. Kandler[2], B. Neumaier[3,2,1]; [1]University Clinic of Cologne, Cologne, GERMANY, [2]Max-Planck-Institute for metabolism research, Cologne, GERMANY, [3]Forschungzentrum Jülich GmbH, Jülich, GERMANY.

Objectives: ^{18}F-Labeling using azide alkyne "click" cycloaddition became a popular method of PET chemistry. Recently, several novel ^{18}F-labeled 1,3-dipoles (other than azides) were applied for the preparation of ^{18}F-labeled small molecules via 1,3-dipolar cycloadditions. Especially, reactions of highly reactive radiofluorinated nitrile oxides could be an attractive alternative to azide "click" labeling. The aim of this work was the development of a novel procedure for protein labeling using nitrile oxide chemistry. Methods: The reaction of *o*- and *p*-[^{18}F]fluorobenzaldehydes ([^{18}F]**1a**,**b**) with hydroxylamine afforded *o*-, *p*- [^{18}F]fuorobenzaldoximes ([^{18}F]**2a**,**b**). *o*- and *p*-[^{18}F]fluorobenzimidoyl chlorides ([^{18}F]**3a**,**b**) - more stable precursors for the generation of nitrile oxides in situ - were obtained via chlorination of [^{18}F]**2a**,**b** using *IODO-GEN precoated reaction vials*. The solutions of the labeling synthons

were added to the corresponding derivatized and native proteins to yield ^{18}F-labeled conjugates. The conjugations were optimized with respect to protein amount. Purification of labeled biopolymers was performed using PD10-column. Results: [^{18}F]**3a**,**b** were obtained in RCY of up to 90% under optimized reaction conditions (1 M HCl, 15 min, 50 °C). [^{18}F]**3a**,**b** were highly stable under strongly acidic conditions (> 5h). Application of water insoluble oxidant allowed to avoid undesirable oxidation and/or denaturation of the proteins. The reaction of [^{18}F]**3a**,**b** with BCN-derivatized BSA as well as with native BSA and Annexin V led to the corresponding radiolabeled isoxazole as well as amidoxime conjugates, respectively, in RCCs of 30-90% within 10 min (pH=7.5-9.0; RT-37°C). Reasonable RCCs (60%) were obtained already with 0.5-5 nmol of proteins. Labeled proteins were isolated in RCPs > 95 after simple gel filtration. Conclusion:The novel radiolabeling procedure allows a fast and efficient radiofluorination of proteins and, consequently, represents an attractive alternative to conventional methods for protein ^{18}F-labeling.

OP098

Synthesis of PET tracers via SN2 radiofluorination under “minimalist” conditions

M. A. Omrane, B. D. Zlatopolskiy, E. A. Urusova, R. Richarz, P. Krapf, B. Neumaier; Institute of Radiochemistry and Experimental Molecular Imaging, Cologne, GERMANY.

Objective: Recently we developed a novel procedure for the preparation of ^{18}F-labeled arenes under “minimalist” conditions using only onium salts as radiolabeling precursors and [^{18}F]fluoride. Neither azeotropic drying, nor base or any other additives were necessary. The aim of this work was to extend this method to the preparation of radiofluorinated aliphatic compounds via SN_2 radiofluorination. Methodology: [^{18}F]Fluoride was eluted from a QMA cartridge with appropriately protected precursors of 5-[^{18}F]FDR, 6-[^{18}F]FDGal and [^{18}F]FET in MeOH. MeOH was evaporated at 65-70 C within 2-3 min, MeCN was added and the resulting solutions were heated to give the corresponding ^{18}F-labeled intermediates. The latter were purified by SPE and thereafter deprotected under acidic conditions. If necessary radiolabeled products were purified by SPE or HPLC. Conjugation of 5-[^{18}F]FDR with the model aminnoxy-substituted compound, methyl 6-aminooxyhexanoate, was optimized with respect to reaction conditions and precursor amount. Results: [^{18}F]F$^-$ was eluted from an anion exchange resin almost quantitatively. Under optimized conditions the appropriately protected 5-[^{18}F]FDR, 6-[^{18}F]FDGal and [^{18}F]FET were prepared from the corresponding 3-*N*,*N*,*N*-trimethylammoniumalkyl(aryl)sulfonyl precursors in RCCs up to >92%, 6% and 71%, respectively. After SPE purification of the radiolabeled intermediate followed by the deprotection step with 1 M HCl (110 °C, 10 min) 5-[^{18}F]FDR was prepared in 48% RCY (EOB) and excellent RCP. No additional purification was needed. The content of D-Ribose (60-80 μg/batch) was sufficiently low to allow an efficient conjugation with methyl 6-aminooxyhexanoate. The corresponding oxime was prepared in RCCs up to 93% and RCPs >96%. *N*-Boc-[^{18}F]FET-OtBu was quantitatively deprotected with DCE/TFA (10 min; 80°C) to give radiofluorinated amino acid in 70% RCC over two steps. Conclusion: The SN_2 aliphatic radiofluorination under “minimalist” conditions is suitable for fast and simple preparation of ^{18}F-labeled compounds. An important additional advantage of this methode is the cationic trimethylammonium tag, which in many cases allows an efficient SPE separation of the radiolabeled compound from the labeling precursor.

OP099

Carbonylation via Conversion of [11C]CO2 into [11C]CO Mediated by [11C]Silane Derivatives

C. Taddei, S. Bongarzone, A. Haji Dheere, A. D. Gee; The Rayne Institute, London, UNITED KINGDOM.

Introduction and AimCarbon monoxide (CO) can be used to synthesise biologically active molecules, such as amides, esters and ketones.[1] [11C]CO is traditionally produced by the gas phase reduction of [11C]CO2 at elevated temperatures[2] or by chemical conversion of CO2 to CO. The chemical conversion of CO2 to CO can be obtained using silane derivatives in two steps: i) CO2 insertion in a silane derivative leading to a silane intermediate followed by ii) CO release triggered by an activator.[3] The produced CO can be transferred in a second vial and coupled with an amine and an organic halide yielding the desired carbonylation product. Herein, this CO2 to CO methodology is applied to carbon-11 labelling by converting [11C]CO2 to [11C]CO and subsequently used to yield [11C]amide-containing molecules. This represents the first carbonylation methodology mediated by a silane derivative reported to date. Moreover, the fully automated synthesis was performed utilising an Eckert & Ziegler Modular-Lab.Method and ResultsThe carbonylation reaction was developed using a simple two-vial reaction setup. In the first vial, [11C]CO2 to [11C]CO conversion was achieved by coupling [11C]CO2 and a silane derivative at room temperature. Following the addition of a decarbonylating agent (activator) with heating, [11C]CO was produced. The release of [11C]CO from the first vial and transfer of

[11C]CO into a second vial was time-monitored. The transfer of [11C]CO to a second vial containing an amine and an organic halide led to the production of the relative [11C]amide derivative. As model reaction, [11C]N-benzylbenzamide was obtained in a high radiochemical purity (>98%) and short synthesis time (~15 min from EOB).ConclusionA novel carbonylation method mediated by a [11C]silane derivative has been successfully developed. This method is an attractive route to produce [11C]carbonyl-containing molecules, obviating the need of gas phase reduction infrastructure. Furthermore, the deigned automated synthesis will be applied to generate new carbon-11 PET tracers.Research SupportThis work was supported by European Commission, FP7-PEOPLE-2012-ITN (316882, RADIOMI), Medical Research Council (MRC, MR/K022733/1) and Biomedical Research Centre award to Guy's & St Thomas' NHS Foundation Trust.References[1] C. OP100

Synthesis and in vivo evaluation of a novel peptide-based N3S1 chelator for 99mTc-labeled radiotracer with enhanced renal clearance

D. Lee, K. Choi; Korea Atomic Energy Research Institute, Jeongeup, KOREA, REPUBLIC OF.

Objectives: Peptide-based N3S1 chelator PXC, which are comprised of amino acids (Pro-X-Cys backbone, X are designated for some amino acids) for radiolabeling with 99mTc has been designed and evaluated for development of radiopharmaceuticals. However, the lipophilicity of the first core structure, Pro-Gly-Cys (PGC) in its RGD complex (PGC-RGD) has resulted in substantial hepatobiliary excretion when administered in tumor-bearing mice. In this study, to improve biological behavior in the biodistribution with the intention of enhancing renal clearance, a novel tripeptide chelating sequence, PKC and its RGD conjugate(PKC-RGD) were synthesized and evaluated in normal mice to explore the effect of chelator on the pharmacokinetic properties. Methods: we have synthesized Pro-Lys-Cys (PKC) by substitution of L-glycine by L-lysine for the preparation of PKC-c(RGDyK) (thus N3S1 chelator-RGD conjugate with L-lysine on the PXC backbone). After preparation of the synthesized chelators-RGD conjugates, the properties of the radiolabeling and a comparison of biodistribution for 99mTc-PGC-c(RGDyK) and 99mTc-PKC-c(RGDyK) were evaluated in vitro and in normal mice, respectively. Results: The target specificity of the resulting PKC-RGD was similar to that of PGC-RGD as determined by a cell binding assay and a competition binding assay. The 99mTc radiolabeling of PKC-RGD resulted in radiochemical yields of 98% under mild conditions at high specific activities. Biodistribution data in normal mice clearly showed a significant decrease in intestinal uptake at 2h postinjection for the 99mTc-PKC-c(RGDyK) compared to the 99mTc-PGC-c(RGDyK) (from 24.35% ID/g to 8.49% ID/g for the GI tract). The 99mTc-PKC-c(RGDyK) biodistribution was also showed by a higher retention of radioactivity in the whole body, but with kidney accumulation over 8-fold higher than observed with 99mTc-PGC-c(RGDyK) at 2h (12.62%ID/g for PKC-RGD and 1.54%ID/g for PGC-RGD, respectively). Conclusions: These results show that the biodistribution may be altered especially concerning lipophilicity resulting in renal rather hepatobiliary excretion. This comparative study make it possible to explore the effects of lipophilicity on the biodistribution of 99mTc-labeled c(RGDyK) through the using different tripeptide N3S1 chelators. Therefore, 99mTc-PKC-RGD may be an attractive alternative for the in vivo imaging of integrin receptors.

OP101

Influence of a novel, versatile bifunctional chelator on radiolabelling, pharmacological and targeting properties of a minigastrin analogue for molecular imaging and therapy applications

J. Pfister[1], D. Summer[1], C. Rangger[1], M. Petrik[2], E. von Guggenberg[1], P. Minazzi[3], G. B. Giovenzana[4], C. Decristoforo[1]; [1]Medical University Innsbruck, Innsbruck, AUSTRIA, [2]Institute of molecular and translational medicine, Faculty of medicine and dentistry, Palacky University, Olomouc, CZECH REPUBLIC, [3]CAGE Chemicals srl, Novara, ITALY, [4]DSF, Università del Piemonte Orientale "A. Avogadro", Novara, ITALY.

Aim: AAZTA (6-[bis(carboxymethyl)amino]-1,4-bis(carboxymethyl)-6-methyl-1,4-diazepane) is a promising chelator with potential advantages over DOTA for radiopharmaceutical applications. Its mesocyclic structure enables fast radiolabelling under mild conditions with trivalent metals including 68Ga for PET, but also 177Lu for radionuclide therapy. Here we describe the conjugation of a bifunctional AAZTA derivative on a model minigastrin derivative as a potential theranostic agent. Materials and Methods: An AAZTA derivative with an aliphatic C9 chain as linker was coupled to a minigastrin [AAZTA0, D-Glu1, desGlu2-6]-minigastrin (AAZTA-MG) and labelled for the experiments with 68Ga and 177Lu using standard labelling protocols. The characterization in vitro included stability studies in different media as well as the determination of the partition coefficient in octanol/PBS (log D). Affinity determination (IC50) and cell uptake studies were performed in A431-CCK2R cells

expressing the human cholecystokinin-2 receptor. Using the same cell lines μPET/CT and ex vivo biodistribution studies were performed in tumour xenograft bearing nude mice for 68Ga labelled compound and normal biodistribution for [177Lu]-AAZTA-MG. Results and Conclusion: AAZTA-MG showed a high radiochemical yields for labelling with 68Ga (>95%),177Lu (>98%) and 111In (>98%) at high SA. The log D value of -3.7 for [68Ga]-AAZTA-MG and [177Lu]-AAZTA-MG indicates a highly hydrophilic character of the complexes. Stability test showed overall high stability in solution with some decomposition in human plasma for 68Ga labelled compound and transchelation towards DTPA for 177Lu. IC50 value of 10.0 nM was determined for AAZTA-MG, which indicates a high affinity binding for the CCK2 receptor with no significant differens for the corresponding natGa and natLucomplexes. Specific cell uptake after 60 min incubation resulted to be >7.5% for [68Ga]-AAZTA-MG in A431-CCK2R cells and >9.5% for the 177Lu labelled counterpart, comparable to other DOTA-MG-analogs. μPET studies in nude mice xenografts revealed high selective accumulation in A431-CCK2R positive tumours of 68Ga-labelled AAZTA-MG (2.5 % ID/g in 1 h post injection), but also comparably higher blood levels as corresponding DOTA-analogs. Biodistribution in normal nude mice for 177Lu labelled compound showed a considerable intestinal (7.3% ID/g) and liver (1.5 % ID/g) uptake. Overall, AAZTA showed interesting properties as bifunctional chelator for peptides providing mild radiolabelling conditions for both 68Ga and trivalent metals having advantages of currently used DOTA. Studies are ongoing to further investigate in vivo targeting properties and stability issues and influence of spacer length on biodistribution.

OP102

Evaluation of configurationally restricted copper-64 labelled bis tetraazamacrocyclic as potential PET agents for CXCR4 expression in oncology imaging

G. S. Clemente, B. P. Burke, S. Nigam, C. Cawthorne, S. J. Archibald; University of Hull, Hull, UNITED KINGDOM.

Introduction: Chemokines are signalling proteins responsible for inducing cell migration. One of their receptors, CXCR4, is commonly over-expressed in several lines of cancer.(1) CXCR4 positive tumours generally have a higher degree of metastatic potential, triggering interest in this receptor as target for drug development and molecular imaging.(2) Following on from previous results published by our group showing the synthesis of novel configurationally restricted bis tetraazamacrocycles that act as CXCR4 antagonists, in which metal complexation enhances both binding affinity and receptor residence time, the radiolabelling with a positron-emitting isotope was attempted to evaluate prospective applications in PET.(3,4) Aim: The main goal of this work is to optimise the radiolabelling of the previously synthesised bis tetraazamacrocyclic with copper-64 (t1/2=12.7h) without the need of structural changes and achieving a radiotracer chemically identical to its characterised cold analogue. Full evaluation of the in vivo characteristics in wild type and CXCR4 over-expressing tumour-bearing mice is currently ongoing. Methods: Mono- and bis-copper versions of the bis tetraazamacrocyclic complex were synthesised by converting 64CuCl2, obtained in cyclotron through 64Ni(p,n)64Cu nuclear reaction, into 64Cu(OAc)2, pH 5.5, followed by complexation of the ligand using a range of temperatures, solvents and reaction times. Formation of the radiolabelled mono-copper complex was attempted by two different approaches: direct chelation of the macrocycle and transchelation with previously coordinated zinc, using stoichiometrically controlled reactions. Bis copper radiotracer was achieved via direct chelation of the non-radioactive mono-copper species. Reactions were followed by radioTLC/HPLC, reformulated and intravenously injected in both normal and CXCR4 over-expressing tumour bearing mice. In vivo competitive blocking studies are being carried out using the clinically licensed CXCR4 antagonist plerixafor (AMD3100). Results: After optimisation of the several radiolabelling approaches, yields above 95% and specific activities up to 9.5 GBq/μmol were achieved. In vivo μPET showed the expected affinity for the CXCR4 receptor.Conclusion: 64Cu radiolabelling of bis tetraazamacrocyclic was successfully achieved to perform in vivo biodistribution studies in CXCR4 over-expressing tumour-bearing mice. The long half-life of 64Cu and receptor residence time could offer improved tumour/background ratios, making it a potential candidate for CXCR4 mapping through PET imaging. Further studies are currently ongoing to fully validate and optimise in vivo properties. M. Palacios-Arreola et al., J Immunol Res, 2014, 2014, 1-8. 2. E. OP103

Efficient production of PET tracers on a preparative scale via copper-mediated radiofluorination under "minimalist" conditions

J. Zischler[1,2,3], B. D. Zlatopolskiy[1,3], P. Krapf[1,3], F. Zarrad[1,2,3], E. A. Urusova[1,3], E. Kordys[1,3], H. Endepols[1,3], B. Neumaier[1,2,3]; [1]University Clinic Cologne, Cologne, GERMANY, [2]Forschungszentrum Jülich GmbH, Jülich, GERMANY, [3]Max-Planck Institute for Metabolism Research, Cologne, GERMANY.

Objectives: Recently two novel methods for the copper-mediated aromatic nucleophilic radiofluorination of (mesityl)(aryl)iodonium salts (MAI) and aryl pinacol boronates (ArBPin) were published. Evaluation of these methods revealed that although both showed high efficacy in small scale experiments, they were inoperative for PET tracer production on a clinical scale. The aim of this work was the development of a versatile and practical procedure for the preparation of PET tracers in a practical scale via Cu-mediated radiofluorination. Methods: Cu catalysts were unstable under conventional strongly basic radiofluorination conditions. Therefore, $^{18}F^-$ was eluted from an anion exchange resin with only 0.06-0.1 mg K_2CO_3 in MeOH ("low base" conditions). After removal of MeOH the residual [^{18}F]KF/K_{222} or 18-crown-6 complex was redissolved in a solution of the appropriate Cu-salt and the corresponding ArBPin or iodonium salt precursor. The reaction mixture was heated for 20 min. Furthermore, the radiofluorination of iodonium salts under "minimalist" conditions (no addition of base and cryptand, no azeotropic drying) was examined. [^{18}F]Fluoride was eluted from the anion exchange resin with the corresponding (mesityl)(aryl)iodonium salt precursor in MeOH. The solvent was evaporated, the residue taken up in a solution of $(MeCN)_4CuOTf$ in DMF and heated. Results: [^{18}F]Fluorobenzene, 4-[^{18}F]fluoroanisole and 3-[^{18}F]fluorobenzaldehyde were obtained under "low base" conditions in RCCs of 26-56% (from MAI) and 41-64% (from ArBPin), respectively. Under "minimalist" conditions, the model compounds were prepared from MAI in RCCs of 78-90%. Protected 6-[^{18}F]fluorodopamine and 4-[^{18}F]fluorophenylalanine were obtained in 71-94% RCCs. Subsequent hydrolysis of the protected intermediates and HPLC isolation afforded the clinically relevant PET tracers in RCYs of 46 and 66%, respectively. Additionally, [^{18}F]DAA1106, a promising tracer for visualization of neuroinflammation, was efficiently prepared in 60% RCY. The specific activity of 4-[^{18}F]FPhe and [^{18}F]DAA1106 amounted to 109 GBq/μmol and 66 GBq/μmol starting from 49.5 and 2.4 GBq, respectively. Conclusion: A robust "low base" protocol for the efficient copper-mediated preparation of [^{18}F]arenes from diaryliodonium salts and aryl pinacol boronates was established. Furthermore, we developed a novel radiofluorination method that combines the advantages of "minimalist" approach to radiolabeling with the exceptional capabilities of copper mediated aromatic nucleophilic radiofluorination.

[18F]DPA-714 as a biomarker for an early detection with PET imaging of synovium inflammation in osteoarthritis model

S. Pesnel[1], F. Gimié[1], V. Meneyrol[1], G. Pottier[2], S. Bénard[1], R. Boisgard[2], F. Dollé[2], E. Jestin[1,3,4]; [1]GIP CYROI - RIPA, Sainte Clotilde, RÉUNION, [2]CEA, I2BM,SHFJ, IMIV UMR 1023 Inserm/CEA/Université Paris Sud /CNRS, Orsay, FRANCE, [3]INSERM, UMR1188 DéTROI, Sainte Clotilde, RÉUNION, [4]Université de la Réunion, Sainte Clotilde, RÉUNION.

Aim: The purpose of this study was to assess the [18F]DPA-714 as novel candidate PET tracer in osteoarthritis model. DPA-714 is a translocator protein (TSPO) ligand. TSPO has been recognized as a biomarker for inflammatory diseases. It has been already shown that TSPO ligands were promising radioligands for targeting arthritis in an mBSA-induced arthritis model in rats. Materials & Methods: Female Wistar rats received a single intra-articular injection of monoiodoacetate (MIA) in the right knee to induce osteoarthritis (OA) lesions and sterile saline in the left knee joint. The animals were scanned in vivo by microPET/CT at 7, 14, 21 and 28 days post-injection to assess the uptake of the tracer in the different stages of the disease. For PET imaging, animals were injected with 38 ± 5 MBq of [18F]DPA-714 and imaging started 45 minutes post-injection. In order to compare this tracer to the current tracers used in clinic: [18F]FDG and [99mTc]oxidronate, the same study was repeated with these 2 tracers. Histology study was performed to correlate the uptake of [18F]DPA-714 to the presence of TSPO and to assess the inflammatory process. Results: The OA lesions were clearly visible on the CT images from day 7 post-injection of MIA. For the 3 tracers the uptake was more important in the right knee compared to the left knee (control). An average increase in activity of 40% for the [18F]DPA-714, 8% for the [99mTc]oxidronate and 7% for the [18F]FDG at day 7 was observed. This uptake increased with the severity of the disease. The increase in activity was higher with the [18F]DPA-714 than with the [99mTc]oxidronate and [18F]FDG from day 7 to day 21. Conclusion: These preliminary results demonstrate that [18F]DPA-714 can be used to follow-up the inflammation in our OA model. Compared to the tracers used in clinic, this tracer allows a better visualization of the disease in the early stages of the disease. Currently a similar study is performed on another model of arthritis (rupture of anterior cruciate ligament in rats).

Liposomal corticosteroid treatment of experimental arthritis can be monitored non-invasively with radiolabeled anti-FAP antibodies

T. van der Geest[1], D. Gerrits[1], J. M. Metselaar[2,3], G. Storm[2,4], T. K. Nayak[5], A. Freimoser-Grundschober[6], C. Klein[6], B. Walgreen[7], M. M. Helsen[7], M. I. Koenders[7], P. Laverman[1], O. C. Boerman[1]; [1]Department of Radiology and Nuclear Medicine, Radboud university medical center, Nijmegen, NETHERLANDS, [2]Department of Targeted Therapeutics, MIRA Institute, University of Twente, Enschede, NETHERLANDS, [3]Department of Experimental Molecular Imaging, University Clinic and Helmholtz Institute for Biomedical Engineering, RWTH-Aachen University, Aachen, GERMANY, [4]Department of Pharmaceutics, Utrecht Institute for Pharmaceutical Sciences, Utrecht University, Utrecht, NETHERLANDS, [5]Roche Pharmaceutical Research and Early development, Innovation Center Basel, Basel, SWITZERLAND, [6]Roche Pharmaceutical Research and Early development, Innovation Center Zurich, Schlieren, SWITZERLAND, [7]Department of Experimental Rheumatology, Radboud university medical center, Nijmegen, NETHERLANDS.

Aim: Rheumatoid arthritis is a chronic autoimmune disorder involving joint inflammation eventually leading to cartilage destruction. Fibroblast activation protein (FAP) is highly expressed by fibroblast-like synoviocytes in arthritic joints. Therefore radioimmunoimaging with anti-FAP antibodies might be an attractive non-invasive imaging tool to monitor therapeutic interventions. Since treatment of arthritis often includes systemic or intra-articular administration of corticosteroids, we treated mice with collagen-induced arthritis (CIA) with prednisolone containing long-circulating liposomes (PLP-LCL) and investigated whether the efficacy of this treatment could be monitored with radiolabeled anti-FAP antibodies. Methods: CIA was induced in male DBA/1J mice. Mice were treated with a single injection of 10 mg/kg PLP-LCL, while the control group received empty LCL. To monitor the therapeutic effect, SPECT/CT images were acquired 24 h after injection of ^{99m}Tc-labeled HYNIC-conjugated anti-FAP antibody, 28H1, at 1, 4 and 9 days after treatment. After image acquisition, mice were dissected to determine radioactivity uptake in joints and uptake was correlated with the macroscopic arthritis score. Results. Treatment of CIA with PLP-LCL suppressed joint swelling. Already at one day after treatment the macroscopic arthritis scores were decreased with 50%. Scores further decreased to only 10% of the initial scores at 4 and 8 days post treatment. In contrast, macroscopic scores increased up to 600% in untreated mice at 8 days. ^{99m}Tc-HYNIC-28H1 showed strongly increased uptake in inflamed joints as compared to non-inflamed joints. Uptake of ^{99m}Tc-HYNIC-28H1 ranged from 1.5 %ID/g in non-inflamed joints to 22.6 %ID/g in severely inflamed joints. Most importantly, uptake of radiolabeled 28H1 in inflamed joints correlated with arthritis score (Spearman's ρ 0.67, $p<0.0001$) and increased with severity of arthritis. Conclusions. SPECT/CT imaging with the anti-FAP antibody specifically visualized arthritic joints and tracer accumulation correlated with the severity of the inflammation. We conclude that SPECT/CT with ^{99m}Tc-HYNIC-28H1 can be used to accurately and noninvasively, monitor the course of CIA in mice.

OP106

Tc-99m-CXCL8 SPECT to image disease activity in inflammatory bowel disease

E. Aarntzen, D. De Jong, R. Hermsen, J. Drenth, O. Boerman, W. Oyen; Radboudumc, Nijmegen, NETHERLANDS.

Aim: Inflammatory bowel diseases (IBD) are defined as chronic relapsing immune-mediated disorders of the gastrointestinal tract. IBD exacerbations are characterized by an extensive recruitment of immune cells into the intestinal wall, which may lead to severe tissue damage. The majority of activated neutrophils are CXCL8-receptor positive. Considering the chronic relapsing character of IBD, accurate and timely diagnosis of an exacerbation is pivotal for early adaptation of the treatment and reduction of the disease burden. The gold standard is endoscopic evaluation, but is invasive and associated with complications. We previously developed a Tc-99m-labeled CXCL8 preparation with good imaging characteristics of inflammation in preclinical models including colitis [Rennen et al. JNM, 2003] and a clinical study [Bleeker-Rovers et al. JNM, 2007]. Materials and methods: In this study, we investigate the accuracy of Tc-99m-CXCL8 SPECT to detect and localize disease activity in a prospective series of patients with IBD. A total of 30 patients (17 Crohn's disease, 14 Ulcerative colitis); disease episodes participated. Ninety-two matched segmental Tc-99m-CXCL8/histology pairs and 72 matched segmental endoscopy/histology pairs were studied. Imaging was performed after injection of 400 MBq Tc-99m-CXCL8 (protein dose: 5 μg/patient). Planar and SPECT acquisitions of the abdomen were performed at 30 min and 4 h after the injection. Results: Uptake of Tc-99m-CXCL8 in intestinal lesions was significantly increased during exacerbations, as compared to scans performed during follow-up, whereas uptake in bone marrow, spleen or liver remained constant. On a per patient basis, sensitivity was 95% (95%CI 77-99%) and 44% (95%CI 14-79. The positive predictive value (PPV) and negative predictive value (NPV) was 81% (95%CI 61-93%) and 80% (95%CI 28-99%). The sensitivity and specificity on a per segment basis for the detection of colitis inflammation was 82% (95%CI 68-92%) and 72% (95%CI 57-

84%), using histology as gold standard. The PPV and NPV was 74% (95%CI 60-85%) and 81% (95%CI 66-91%). False positive segments included 'faint uptake' in the ascending colon (4 patients), pseudopolyps in the transverse colon (1 patient) and terminal ileum that could not be confirmed by histology or endoscopy (1 patient). Conclusion: Tc-99m-CXCL8 SPECT provides a novel imaging technique to target neutrophil recruitment to the intestinal wall, which may be helpful to assess moderate to severe exacerbations of IBD. Further validation studies are warranted to potentiate Tc-99m-CXCL8 SPECT as a biomarker to scale up or step down treatment with immune modulating drugs in a personalized fashion.

OP107

Role of 18F-FDG PET/CT in the evaluation of response to antibiotic therapy in patients affected by infectious spondilodiscitis

F. Simone, **A. Niccoli Asabella**, D. Rubini, A. Notaristefano, F. Iuele, G. Rubini; Nuclear Medicine Unit, D.I.M., University of Bari "Aldo Moro", Bari, Italy, Bari, ITALY.

Aim: to evaluate the usefulness of 18F-FDG PET/CT to detect the early response to antibiotic therapy in patients affected by infectious spondilodiscitis and to compare the role of 18F-FDG PET/CT and MRI in post-treatment evaluation.Materials and Methods: 15 patients (12 M, 3 F), with mean age 65±13 years old, with typical clinical symptoms of Infectious Spondilodiscitis (pain, fever and increase of inflammatory indexes) and confirmed by blood culture or vertebral biopsy underwent within three day-interval a 18F-FDG PET/CT and Magnetic Resonance (MR) at "baseline" and after antibiotic therapy with Teicoplanine, Levofloxacine and Rifampicine. Semiquantitative parameters at 18F-FDG PET/CT "baseline" SUV max1, MTV1 and TLG1 and after therapy SUV max2, MTV2 and TLG2 of involved vertebrae were calculated. Follow-up period of at least three months was available for all patients.T-student test for paired groups was performed to compare baseline and after therapy 18F-FDG PET/CT semiquantitative parameters.Results: According to 18F-FDG PET/CT parameters all patients showed a response to antibiotic therapy. All patients were positive at "baseline" MR of the spine, while at follow-up, 7/15 patients showed MR signs of infection and were considered "positive", and 8/15 showed resolution of infectious condition and, therefore they were considered "negative". A statistical significant difference between 18F-FDG PET/CT "baseline" and after antibiotic therapy was found for all semiquantitative parameters: SUV max (t=5.8, p=0); MTV (t=2.66, p=0.02); TLG (t=4.53, p=0). The comparison between the "baseline" and "after treatment" 18F-FDG semiquantitative parameters showed a significative reduction of all parameters. This reduction was relevant also in patients with positive post-treatment MR. This bias is probably due to the tissue remodelling in the very immediate phase post-treatment, resulted positive at MR and negative at 18F-FDG PET/CT. Clinical follow-up of at least three months confirmed these results.Conclusions: 18F-FDG PET/CT is useful to detect the early response to antibiotic therapy in patients affected by infectious spondilodiscitis. 18F-FDG PET/CT semiquantitative parameters provide critical diagnostic information of the infectious process. 18F-FDG PET/CT should be considered as first-line exam in the diagnosis of spondilodiscitis while MR should be preferred for delayed evaluation.

OP108

The role of 18FDG-PET/CT for interim evaluation of therapy response in spondylodiscitis

P. Ghedini[1], C. Nanni[1], I. Petri[1], L. Zanoni[1], I. Grassi[1], S. Cambioli[1], D. Fiorenzo[2], S. Fanti[1]; [1]Nuclear Medicine, University Hospital S. Orsola-Malpighi, Bologna, ITALY, [2]Department of Diagnostic Imaging, University Hospital S. Orsola-Malpighi, Bologna, ITALY.

Aim: The aim of this study is to examine the role of the 18F-FDG-PET/CT in patients affected by spondylodiscitis and analyzing new possible parameters to early evaluate therapy response. Materials and Methods: We retrospectively enrolled 61 patients (21 female, mean-age 61) with diagnosis of spondylodiscitis. Among the 61 patients, 11 had tubercular, 1 fungal and 49 pyogenic spondylodiscitis. All patients underwent 18F-FDG-PET/CT baseline scan with determination of C-reactive protein (CRP) value and a second scan after 2-4 weeks of therapy. We analyzed SUV of both scans, delta-SUV (SUV1-SUV2/SUV1) in comparison with CRP levels during therapy. Furthermore we evaluated the volume of the infection, that we named "metabolic infection volume" (MIV) in the first and second scan. We selected a threshold of 50% of Lesion SUV1-2 for MIV definition. Delta-MIV (MIV1-MIV2/MIV1) were calculated and compared with SUV changes. Lesion-to-liver (LLR) ratio, lesion-to-mediastinal ratio (LBR), delta-LLR and delta- LBR after therapy were evaluated in every patients. Relationship between these different SUV and MIV parameters with therapy response and clinical outcome were investigated. Results: The mean SUV at diagnosis was 9,7+/-3,3. The mean CRP level at diagnosis was 2,9+/-2,8 mg/dl. SUV1 was not correlated with the CRP1 level at diagnosis (p=0.6) and SUV2 was not correlated with CRP2 (p=0.71). In responders patients, SUV2 and CRP2 were significantly lower than SUV1 and CRP1 ($p<0.001$ and $p<0.0001$ respectively). MIV2, LLR2 and LBR2 were also significantly lower than MIV1, LLR1 and LBR1 ($p<0.003$). ROC curves for delta-SUV showed a sensitivity of 87 % and a specificity of 82% with a cut-off of 33%. ROC curves for SUV2 showed a

sensitivity of 83% and a specificity of 46% with a cut-off of 5.0. ROC curves for CRP2 showed a sensitivity of 47% and a specificity of 82% with a cut-off of 0.71 mg/dl. ROC curves for delta-CRP showed a sensitivity of 82% and a specificity of 55% with a cut-off of 70%. OC curves for delta-LLR showed a sensitivity of 88% and a specificity of 87% with a cut-off of 30%. Delta-MIV correlate with delta-SUV. Conclusions: Delta-SUV provided a higher sensitivity and specificity in responders patients. SUV2 provided significantly lower specificity. SUVparameters performed better than CRP level. MIV, despite difficuties in its delineation, represented a possible useful parameter in infection with high metabolism grade. Finally, LLR provided a significantly higher specificity, with comparable sensitivity.

OP109

A Direct Comparison of 18F-FDG and 68Ga-DOTANOC PET/CT for Detection of Cardiac Sarcoidosis: Diagnostic Accuracy and Inter-observer Variability

L. C. Gormsen, A. Haraldsen, S. Kramer, W. Kim, P. Borghammer; Aarhus University Hospital, AARHUS C, DENMARK.

Aim: Cardiac sarcoidosis (CS) is a potentially fatal condition resulting in increased risk of sudden cardiac death. Overall survival in CS patients is substantially increased by corticosteroid therapy and correct diagnosis is therefore important. Unfortunately, no single test or imaging modality has acceptable diagnostic accuracy and the CS diagnosis is still based on insufficient clinical criteria. 18F-FDG PET/CT has previously shown some diagnostic promise, but is hampered by physiological glucose uptake in the myocardium. 68Ga-DOTANOC binds to somatostatin receptors on inflammatory cells in sarcoid granulomas. We compared the diagnostic accuracy of 68Ga-DOTANOC and 18F-FDG for diagnosing CS, and assessed inter-rater agreement among three readers. Materials and methods: 19 patients (7 female) with suspected CS were prospectively recruited in the trial. 18F-FDG (5 MBq/kg) and 68-Ga-DOTANOC (3 MBq/kg) scans were performed 60 and 90 minutes post injection, respectively, on a Siemens Biograph 64 scanner with <7 days between scans. Prior to 18F-FDG PET, participants were instructed to fast for >12 hours. PET/CT images were reviewed by three experienced nuclear medicine physicians. Studies were categorized as positive, negative, or inconclusive. In case of reviewer disagreement, final PET diagnosis was based on majority decision. To assess diagnostic accuracy of both PET tracers, we used the established reference standard based on CS criteria laid out by the Japanese ministry of Health and Welfare combined with clinical follow up. Inter-observer variability for both tracers was calculated using Fleiss kappa for multiple observers and trichotomous outcome. Results: Based on the reference standard, 3/19 patients suffered from CS, which was in line with the expected proportion. 10/19 18F-FDG scans were rated as inconclusive by consensus diagnosis rendering calculations of diagnostic accuracy impossible. In contrast, accuracy was 100 % for 68Ga-DOTANOC based on the consensus diagnosis among readers. Interestingly, Fleiss kappa was extremely poor for 18F-FDG PET (combined kappa 0.11, NS) showing that reviewers disagreed greatly in interpreting the images. Fleiss kappa was somewhat better for 68Ga-DOTANOC (0.36, p=0.001), which is fair agreement - but still demonstrates significant inter-rater disagreement. Conclusion: Despite relevant and recommended patient preparations, 18F-FDG PET/CT images of the heart were extremely hard to interpret for signs of CS resulting in disappointingly low concordance rates among reviewers and correspondingly poor diagnostic accuracy. By contrast, 68Ga-DOTANOC PET/CT had excellent diagnostic accuracy with the caveat, that inter-observer variability was significant. 68Ga-DOTANOC PET/CT looks promising as an alternative CS PET tracer with images preferably reviewed by multiple readers.

OP110

Comparison between ^{18}F-FDG PET/CT and ^{99m}Tc-HMPAO-labelled leukocyte SPECT/CT in 50 patients with suspected osteomyelitis

P. Ferro[1], G. Cusato[1], S. Fiorino[1], M. Spallino[1], C. E. Popescu[2], R. Sara[2], L. Conversano[2], M. Milella[2], C. Rossetti[2]; [1]Università Milano-Bicocca, Milano, ITALY, [2]Ospedale Niguarda, Milano, ITALY.

Aim:Early diagnosis is crucial for the management of bone infections and surrounding tissue involvement in suspected osteomyelitis. Several diagnostic tools are currently available , such as x-ray, CT, microbiological cultures, and serological tests. Nuclear Medicine could be useful, with ^{99m}Tc-HMPAO labelled leukocyte SPECT/CT (HMPAO-SPECT/CT) and ^{18}F-FDG PET/CT (FDG-PET/CT) scan.The aim of our preliminary study was to evaluate and compare the clinical value of HMPAO-SPECT/CT and FDG-PET/CT in the diagnosis of bone infections.Methods:We retrospectively analysed 50 patients (29 males, 21 females, age range 24-84 years) with suspected osteomyelitis who underwent both FDG-PET/CT and HMPAO-SPECT/CT.Clinical symptoms, serological tests (PCR values), CT scans and ongoing antibiotic therapy at the time of the studies were analysed.FDG-PET/CT and HMPAO-SPECT/CT were considered “positive” or “negative” on agreement of 3 independent observers on qualitative analysis of the images; SUV max was measured in each detected lesion and correlated to PCR levels.Final diagnosis of infection was based on microbiological culture, serological tests (PCR) and clinical

follow-up. HMPAO-SPECT/CT and FDG-PET/CT were compared with each other considering separately bone and soft tissue.Results:FDG-PET/CT showed higher values of sensibility (90 vs 44% in bone and 94 vs 59% in soft tissue), negative predictive values (NPV) (83 vs 53% in bone, and 85 vs 52% in soft tissue) and accuracy (88 vs 64% in bone and 88 vs 70% in soft tissue) than HMPAO-SPECT/CT. On the contrary HMPAO-SPECT/CT exams demonstrated better specificity (95 vs 83% in bone and 94% vs 73% in soft tissue) and positive predictive value (PPV) (93 vs 90% in bone tissue and 95 vs 89% in soft tissue) (p<0,006).In 14/50 patients (28%) FDG-PET/CT was positive whereas HMPAO-SPECT/CT was negative. All these 14 patients were under antibiotic therapy during investigations and their clinical history suggested a chronic process.We observed a correlation between SUV max and PCR values: SUV max was higher in patients with positive PCR levels (SUV max 2,45-12,72 corresponding to PCR 2,3-17,6 mg/dl).Conclusion:18F-FDG-PET/CT and 99mTc-HMPAO-SPECT/CT scans are a reliable support tool for clinical and serological data in the evaluation of patients with suspected osteomyelitis, providing additional information on anatomic localization and extent of the infection processes. Either in bone and soft tissue, FDG-PET/CT has proven to have higher sensibility, accuracy and NPV while HMPAO-SPECT/CT shows relatively higher specificity. 99mTC-HMPAO-SPECT/CT could be less effective in patients with chronic disease and suffered from the ongoing antibiotic therapy.

OP111

The added value of 18F-FDG PET for the staging of patients with invasive fungal infections

A. O. Ankrah[1,2], A. W. J. M. Glaudemans[1], E. F. J. de Vries[1], R. H. J. A. Slart[1,3], R. A. J. O. Dierrckx[1], M. M. Sathekge[2], H. C. Klein[4]; [1]Department of Nuclear Medicine and Molecular Imaging, University Medical Center Groningen, Groningen, NETHERLANDS, [2]Department of Nuclear Medicine, University of Pretoria, Pretoria, SOUTH AFRICA, [3]Biomedical Photonic Imaging Group, University of Twente, Enschede, NETHERLANDS, [4]Department of Psychiatry, University Medical Center Groningen, Groningen, NETHERLANDS.

^{18}F-FDG PET has proven added value in many malignant diseases, but its role in infectious diseases still has to be defined. It is important to correctly stage invasive fungal infections at an early time point to make proper clinical decisions, since fungal infections often occur in immunosuppressed patients, to whom the infection may be life-threatening.The aim of this study was therefore to determine the added value of ^{18}F-FDG PET compared with conventional imaging for the staging of patients with fungal infections.Materials and methods- All patients with a proven fungal infection who underwent a ^{18}F-FDG-PET/CT between October 2009 and December 2014 were retrospectively included. Fungal infection was proven by histology or cultures. All patient dossiers were checked for infection parameters, clinical history, and imaging procedures. All ^{18}F-FDG-PET/CT scans were performed on a Biograph mCT TOF system (Siemens) according to the EARL guidelines. All PET findings were compared to the findings based on all other imaging modalities combined in order to determine if ^{18}F-FDG -PET/CT could provide more information. The ^{18}F-FDG-PET findings were also correlated to the infection markers in the blood.Results- 9 males (32%) and 19 females (68%) between the ages of 6 months up to 75 years were included. All the patients were immunocompromised, mainly due to treatment of an underlying haematological malignancy (64%) or organ transplantation (21%). Indications for the scans included unexplained fever, determining the absence of fungal infections before proceeding with stem cell transplant and in some cases to determine other sites of fungal infections.In total, ^{18}F-FDG-PET revealed 107 fungal infection lesions, compared to 60 lesions detected by conventional imaging. The SUVmax of all lesions was heterogeneous, varying from 1.14 To 17.86 (mean 5.36) ^{18}F-FDG PET detected more lesions than conventional imaging in 19 (68%) patients. The majority of these patients had extra-thoracic disease. In 4 (14.2%) cases, ^{18}F-FDG-PET/CT noted disease activity where findings on other modalities were equivocal. In total, ^{18}F-FDG-PET/CT added diagnostic information in 23 patients (82%) which potentially could influence clinical decisions. No correlation was found between the infection parameters and ^{18}F-FDG-PET/CT findings.Conclusion- ^{18}F-FDG-PET/CT has significant added-value over conventional imaging in the initial evaluation of patients with invasive fungal infections. The main added value is in finding lesions outside the thoracic region. To our opinion, whole body ^{18}F-FDG-PET/CT accompanied by high-resolution CT scan of the chest should be the imaging modality of choice in (suspected) fungal infections.

Pixel-based Source Depth Measurement for Cerenkov Luminescence Imaging

L. Altabella[1], C. R. Gigliotti[1], F. Boschi[2], A. E. Spinelli[1]; [1]San Raffaele Scientific Institute, Milano, ITALY, [2]University of Verona, Verona, ITALY.

Aim: Optical tomography represents a challenging problem in optical imaging because of the intrinsically ill-posed inverse problem due to photon diffusion. Cerenkov luminescence

tomography (CLT) for optical photons produced in tissues by several radionuclides (i.e.: 32P, 18F, 90Y), has been investigated using both 3D multispectral approach and multiviews methods. Difficult in convergence of 3D algorithms can discourage to use this technique to have information of depth and intensity of source. For these reasons, we developed a faster 2D corrected approach based on multispectral acquisitions, to reconstruct source depth and its intensity. Methods: Monte Carlo simulations were developed using GAMOS plug-in for GEANT4, validated for Cerenkov optical photon production as well as optical photon transport. Experimental data were acquired using IVIS SpectrumCT (Perkin Elmert, USA). We scanned a capillary (1.0 mm diameter) filled with 0.5 MBq of 32P-ATP. Capillary was placed inside slices of chicken breast to simulate tissue scattering. We considered three thickness of chicken breast: 6, 9 and 11 mm. According to Beer Lambert law we can derive the unknown source depth, using a pixel-wise fit of several images acquired using different spectral filters from 560 nm to 660 nm with a pass of 20 nm. More precisely we fit radiance (p/sec/cm2/sr) in each location for all the images as function of different μeff that depends on the filter wavelength. Considering a two parameters linear fit of the intensity logarithm, corrected both for theoretical Cerenkov emission spectrum and for diffusive optical transport as implemented by Coquoz, we derived a pixel-based depth source map and a 2D depth corrected intensity source map. Results and conclusion: We obtained a pixel-based source depth reconstruction with a maximum error in source region of 10% for 6 mm source, and less than 3% for the deeper sources. Combining depth information and source intensity, we can recognize and discriminate source characteristics in terms of intensity. This is particularly interesting in animal model with several tumor masses. In these cases image acquired from animal surface can mislead for example in presence of deeper but more intense tumor. This work demonstrates that it is possible to obtain reliable information concerning the Cerenkov optical source using a 2D multispectral imaging approach. Further developments of this work consist of applying this method on in vivo studies.

OP113

Correcting for Patient Motion on a Solid State Multiple Pinhole Dedicated Cardiac Camera

S. Redgate[1], D. C. Barber[2], J. W. Fenner[2], A. Al-Mohammad[3], J. C. Taylor[1], M. B. Hanney[1], W. B. Tindale[1]; [1]Nuclear Medicine, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, UNITED KINGDOM, [2]Medical Physics Group (Cardiovascular Science), University of Sheffield, Sheffield, UNITED KINGDOM, [3]Cardiothoracic Directorate, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, UNITED KINGDOM.

Aim: Patient motion ≥13mm introduces artefacts into myocardial perfusion images[1]. Procedure guidelines recommend correction, which involves alignment of the projections prior to reconstruction. Multiple pinhole cardiac cameras acquire data at all angles simultaneously, presenting the potential for 3D motion correction. The aim of this study was twofold: a) to perform simulations to determine the magnitude and duration of motion that introduces significant motion artefacts on this system and b) to develop a technique for 3D motion correction and test this on patient studies. Materials and Methods: Phantom images were acquired in the centre of the field of view and offset in the X, Y and Z directions. These were used to simulate 5-20mm creep and step motion, with step durations of 30, 60, 90 and 180s. Qualitative assessment, through blinded reporting and quantitative assessment through calculation of the total perfusion defect (TPD) was performed to identify motion artefacts (TPD ≥5.5%). Motion correction was performed by reframing the list mode data into a series of 30s images, reconstructing each frame and then registering and summing these to produce a corrected image. This was validated on images with simulated motion and applied to images with no motion. Additionally, forty patient studies were assessed for motion and the motion correction algorithm was applied to studies with significant motion. Results: Qualitative analysis identified motion artefacts for ≥10mm motion. Quantitative analysis identified artefacts for ≥11mm 180s step motion and >15mm creep motion. No artefacts were identified for step motion with a 30s duration, confirming that this is a suitable reframing duration for motion correction. Motion correction visually removed 9/10 motion artefacts on the phantom simulations and reduced all the TPD values to ≤4%. When applied to images with no motion there was no difference between the original and motion corrected images or TPD values. Two patients (5%) were identified as having significant superior-inferior patient motion and motion correction improved the appearance of the anterior and inferior walls on these studies. This is a retrospective analysis, but arguably it might have changed patient management in a couple of cases. Conclusion: Patient motion ≥10mm magnitude and >30s in duration introduces significant motion artefacts into myocardial perfusion images acquired on a multiple pinhole cardiac camera. Motion correction, as described, successfully corrects for patient motion artefacts in this study. Correction of patient motion on this system has been shown to be technically feasible and accurate. 1. J Nucl Med,42(5) 4687-694

Partial volume correction of Image Derived Input Functions using a novel Single Target Correction Technique

J. C. Dickson[1], K. Erlandsson[2], H. Sari[2], S. Wan[1], A. Groves[2]; [1]University College London Hospital NHS Foundation Trust, London, UNITED KINGDOM, [2]University College London, London, UNITED KINGDOM.

Introduction: The move to non-invasive image derived input functions (IDIF) in PET has been hampered by difficulties correcting for partial volume effects (PVE) in the volumes of interest used to produce the input functions. We have previously attempted to use Rubidium-82 PET to quantify perfusion in colorectal cancer tumours [1]. In this paper we introduce a novel single target correction (STC) technique [2], and apply it to IDIF derived from dynamic Rubidium-82 PET images of the femoral arteries. Methods: Six patients with suspected colorectal cancer were involved in this study. Each had a dynamic Rubidium-82 PET scan and CT perfusion to assess tumour perfusion. To define a volume of interest for the IDIF and for partial volume correction, the femoral artery was segmented from the CT perfusion scan. The dynamic PET data was then registered to this VOI using a registration between the CT perfusion scan and the CT scan for attenuation correction that was acquired for PET. With segmented vessel and PET data in the same space, the STC partial volume correction (PVC) technique was applied to the PET data. In essence, the technique is an evolution of the Müller-Gartner method, which uses true volume extent and an estimate of the Point Spread Function (PSF) to correct the PET data. In this study we used an experimentally derived PSF of 11.4mm (FWHM). Changes to IDIF pre and post correction were assessed by measuring the change at peak, where spill-out factors are greatest; and in final PET frame where spill-in factors play a larger role. The effect on values of tumour K1 was also assessed. Results: The peak IDIF uptake went up on average by a multiple of 2.80 [Range: 2.12-3.43] when partial volume correction was applied. This is not unexpected given the PSF of Rubidium PET and the typical diameter of femoral arteries. In comparison, in the last frame where spill-in factors to the IDIF become more of an issue the uptake increased on average by a multiple of 1.40 (Range: 1.22-1.62] with corrections applied. As a consequence, K1 is reduced on average by 65.43% [Range: 34.37-79.67] after correction. Conclusions: PVC using a single target technique make substantial changes to the IDIF and estimated kinetic parameters. References: 1. Voxel-level dosimetry with a grid-based Boltzmann solver for patient-specific nuclear medicine dosimetry

J. Mikell[1,2], F. Mourtada[3], T. Wareing[4], **S. C. Kappadath**[1,2]; [1]UT MD Anderson Cancer Center, Houston, TX, UNITED STATES, [2]UT Graduate School of Biomedical Sciences, Houston, TX, UNITED STATES, [3]Christiana Care Health System, Newark, DE, UNITED STATES, [4]Varian Medical Systems, Pala Alto, CA, UNITED STATES.

Aim: MIRD assumes uniform uptake at the organ level and patient geometry based on anthropomorphic phantom geometry. Voxel-level dosimetry models are able to overcome these shortcomings and provide patient-specific dosimetry. Full radiation transport solutions that solve the linear Boltzmann transport equation (LBTE) under patient-specific conditions are considered to be more accurate. Deterministic grid-based Boltzmann solvers (GBBS) are full transport solutions to the LBTE in addition to Monte Carlo (MC) approaches. We have validated GBBS Attila v8.0.0 with MC DOSXYZnrc for beta and gamma sources in both homogeneous and heterogeneous medium with clinically acceptable uncertainties. The aim of this work is to implement GBBS for patient-specific voxel-level nuclear medicine dosimetry and compare its performance against MC. Materials and Methods: We investigated GBBS using single time-point quantitative SPECT/CT for 90Y-glass-microsphere HCC patient and 131I-NaI thyroid cancer patient with lung metastases. The gold standard for voxel-level dosimetry was MC. Tissue material and density were obtained from CT while activity distribution was from SPECT. For 90Y we calculated absorbed doses from only the 90Y beta spectra. For 131I we simulated the auger+conversion electrons, beta particle spectra, and gamma+x-ray spectra. To perform patient-specific GBBS, the required tetrahedral mesh geometry was generated adaptively using tetgen v1.5.0. To control the adaptation, a mesh-sizing function was generated based on the activity, material, and gradient of the material distribution. Mapping of material, density, and activity to tetrahedrons was done using the nearest voxel centroid to the tetrahedron centroid. The electron energy cutoff was 100 keV for 131I (200 keV for 90Y) while the photon energy cutoff was 1 keV. Quantitatively, we compared mean, minimum, maximum absorbed dose to tumors and normal tissues. Qualitatively, we compared dose-volume histograms (DVH) and line profiles through tumors. Results: GBBS for 90Y took 38s, while the I131 took 606s (208s for auger+conversion electrons, 94s for beta, and 304s for gamma+x-ray component). For 90Y the GBBS mean and maximum absorbed dose to tumor and normal liver were within 2.3% of MC. For total I131 the mean and maximum absorbed dose to tumors were within 4.3%; mean and maximum doses to left and right lung were within 3% and 7.6%, respectively. Line profiles of voxel-doses through

tumors and DVHs visually agreed well between GBBS and MC. Conclusion: GBBS with adaptive meshing provides patient-specific nuclear medicine dosimetry with accuracy comparable to MC and computation speeds suitable for routine clinical practice. Grant support NIH/NCI R01 CA138986.

OP116

FDG-PET/CT of Bronchial Carcinoma Under Neoadjuvant Chemotherapy: Background Based Adaptive Volume Metrics Outperform TLG and MTV in Predicting Therapy Response

I. A. Burger[1], R. Casanova[1], S. Steiger[1], P. Stolzmann[1], M. W. Huellner[1], P. Veit-Haibach[1], A. Soltermann[1], C. R. Schmidtlein[2]; [1]University of Zurich, Zurich, SWITZERLAND, [2]Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES.

Purpose: Tumor response assessment to chemotherapy using FDG PET metrics is gaining acceptance. The most common PET metric is maximum standardized uptake value (SUV_{max}). However, several studies have suggested that the metabolically active tumor volume (MTV) or the total lesion glycolysis (TLG) are superior for assessing tumor burden and probably also response to therapy. The optimal method for defining MTV and TLG is still controversial; initially all voxels with FDG activity above 42% of SUV_{max} were used. Recently we have suggested a method that adapts to the local background to determine the background subtracted lesion activity (BSL) and the background subtracted volume (BSV). It was the aim of our study to investigate the correlation between PET metrics and therapy response in non-small cell lung carcinoma (NSCLC). Patients and Methods: Forty-six NSCLC patients were retrospectively identified, the PET/CT data before and after neo-adjuvant chemotherapy were analyzed regarding SUV_{max}, MTV, TLG, BSL and BSV on both scans and the relative changes were calculated. The tumor regression grade (TRG) as an indicator of tumor response was assessed on H&E stained sections of the corresponding surgical specimens using a 4-tiered scale. TRG was correlated with the relative change of all PET metrics using Spearman rank test. Results: Both the change in tumor size and SUV_{max} did correlated with the TRG with $p = 0.038$ and $p < 0.001$, respectively. The PET volume metrics based on a fixed threshold of SUV_{max} did not correlate with TRG (TLG: $p = 0.389$ and MTV: $p = 0.420$). However, both background activity based PET volume metrics BSL and BSV significantly correlated with TRG ($p = 0.001$ for both). Conclusion: Volume based PET metrics using a fixed threshold (42% SUV_{max}) for delineation did not correlate with TRG. However tumor regression correlated well with SUV_{max} and both background based PET volume metrics BSL and BSV.

OP117

Automated organ segmentation in pre-clinical 4D PET/CT images

C. Maaß[1], J. Avelar Rivas[1], A. A. Attarwala[1], B. Abualhaj[1], S. Niedermoser[2], C. Wängler[3], G. Glatting[1]; [1]Medical Radiation Physics/Radiation Protection, Medical Faculty Mannheim, Heidelberg University, Mannheim, GERMANY, [2]Molecular Imaging and Radiochemistry, Department of Clinical Radiology and Nuclear Medicine, Medical Faculty Mannheim, Heidelberg University, Mannheim, GERMANY, [3]Biomedical Chemistry, Department of Clinical Radiology and Nuclear Medicine, Medical Faculty Mannheim, Heidelberg University, Mannheim, GERMANY.

Aim: Treatment planning in molecular radiotherapy relies on the estimation of time-activity curves [1]. To provide an optimal therapy, this estimation needs to be accurate and reproducible (observer independent).The aim of this work was (1) to implement an algorithm for the automated segmentation of relevant structures (tumour, organs at risk) in pre-clinical 4D PET/CT images and (2) to determine the optimal number of clusters.Materials and Methods: Biodistribution of 18F-SiFalin-PEG1-TATE [2] in six AR42J tumour bearing mice was obtained from a preclinical PET/CT (Bruker BioSpin MRI GmbH, Ettlingen, Germany). This tracer binds specifically to the somatostatin receptor subtype 2, which is overexpressed in neuroendocrine tumours.An in-house software for automated organ segmentation of 4D PET/CT images was implemented in MATLAB (R2014b, MathWorks, Natick, Massachusetts, USA). This algorithm clusters time-activity curves voxelwise using k-means. The optimal number of clusters depends on the region and was determined by minimising (1) the Calinski-Harabasz-criterion (ratio of within to outer cluster variances) and (2) the relative deviation (RD) between clustered and actual organ volumes. Clustered organ volumes were calculated by summing up all clusters within an organ.Reproducibility of the algorithm was tested by determining both the optimal number of clusters and the time-activity curves five times for tumour and kidneys (averaged over six mice).Accuracy of the algorithm was evaluated by comparing clustered organ volumes and manually drawn volumes to actual organ weights.Results: The mean numbers of optimal clusters were (1) 10±2 and 4±1 and (2) 7±3 and 9±2 for tumour and kidneys, respectively.RDs of the manually drawn and actual tumour and kidney volumes were (-1 ±54)% and (-17±14)%. RD of the clustered and actual volumes was for tumour and kidney (1) (-37±38)% and (-10 ±19)%, (2) (0±6)% and (3±4)%.Conclusion:Automated organ segmentation of 4D pre-clinical images is reproducible and observer independent. The optimal number of clusters is crucial and can be determined using the presented method (2). Thus, an accurate and automated determination of time-

activity curves is possible.Literatur:1.Glatting G, Bardies M, Lassmann M. Treatment planning in molecular radiotherapy. OP118

Does Reducing Reconstruction Voxel Volume / Increasing Matrix Size Improve Lesion Detectability? A phantom and clinical feasibility demonstration using next generation digital PET/CT

J. Zhang[1], K. Binzel[1], C. Wright[1], V. Nagar[1], P. Bardos[1], P. Maniawski[2], M. V. Knopp[1]; [1]The Ohio State University, Columbus, OH, UNITED STATES, [2]Philips Healthcare, Cleveland, OH, UNITED STATES.

Aim: The replacement of the photomultiplier with a solid state, digital photon counting detector is a technological leap that leads to higher photon counting rates, less dead time and improved dose response linearity. PET has traditionally used comparatively to CT and MRI smaller reconstruction matrix and thus larger voxel volumes. This study investigates if lesion detectability can be improved by larger matrix reconstruction of phantoms and in clinical oncologic PET/CT.Materials and methods: A Philips Vereos TF 64 digital PET/CT (Cleveland, OH) was used for NEMA and Jaszczak phantom acquisitions as well as in 20 clinical patients referred with suspected malignancies. Clinical whole body PET scans were acquired after average injection of 480 MBq 18F-FDG with 90s per bed position, 40% overlap and a 576mm FOV. Images were reconstructed in 144x144 matrix with voxel volume of 4 x 4 x 4 (64) mm3, 288x288 matrix with voxel volume of 2 x 2 x 2 (8) mm3 voxel volume, and 576x576 matrix with voxel volume of 1 x 1 x 1 (1) mm3. All three reconstructed image data sets were assessed by comparative analysis using two independent readers. Lesion detectability as well as confidence of diagnostic relevance was assessed, however only lesions of >2cm in unidimensional diameter on CT included. The phantoms were evaluated against the known parameters and the recovery coefficients calculated.Results: Image quality of all data sets and reconstruction volumes was classified as satisfactory. 48 lesions are included in this evaluation, all of them visualized on the largest reconstruction matrix. 11 lesions were only confidently detected on the 1 mm3 voxel reconstructed images. 13 lesions were first visualized on the 2 mm3 voxel and also seen on the 1 mm3 but not on the 4 mm3 voxel reconstructed images. Overall, readers consistently rated the 288 matrix images to be preferable over the 144 matrix images. The 576 matrix images were rated on average 38% more preferable than the 288 matrix images and equivalent to the 288 matrix in all remaining cases. The 1 mm3 voxel reconstructed phantom data presented consistently the best recovery coefficient.Conclusion: Larger matrix size / reduced voxel volume reconstruction substantially improved clinical lesion detectability and on phantom scans calculated recovery coefficients. The improved counting capabilities of the digital detector system appears to enable a consistent utilization of larger reconstruction matrix that was shown to improve lesion detection by substantially reducing partial volume effects.

OP119

A New Statistical Model For Quantifying Tumor Heterogeneity in Emission Tomography

J. Varga[1], A. Forgács[2,1]; [1]University of Debrecen, Debrecen, HUNGARY, [2]ScanoMed Ltd., Debrecen, HUNGARY.

Beside biological heterogeneity, the scatter of voxel values in a tumor volume is also influenced by partial volume effect (PVE) and noise. The smaller the object, the contribution of PVE is more significant. We propose a procedure to separately access the significance of biological heterogeneity. Methods: We estimate a homogeneous tumor volume that - after convolution with the PSF - would best approximate the observed distribution in a neighborhood of the tumor. We alternatingly estimate the tumor mask, and the tumor and background levels. We statistically test the null hypothesis that the variance inside the tumor volume in the difference image (observed - homogeneous distribution blurred) is fully explained by noise. An F-test is applied to the ratio of observed and expected variances (based on a reference area), with corrected degrees of freedom taking into account that neighboring pixels are correlated. First we tested the algorithm on 2-dimensional slices of simulated and phantom data. Our *simulation* data consisted of rings with 2 to 16 pixels external radius (4 mm/pixel), and internal radius half of that. Ring to background activity ratio was 4. Poissonian random noise with variation coefficient of 0.3, 1, 3, 10, and 30% was added to each, resulting in 40 simulated images. For the *phantom* PET studies we used (a) the IEC body phantom containing 6 fillable spheres (diameters: 10, 13, 17, 22, 28 and 37 mm). The sphere-to-neighborhood activity ratio was 10. (b) A special heterogeneous phantom consisted of seven 2 mL syringes, 2-3-2 of them filled with different concentrations of C-11, immersed in F-18-labeled water. 12 images were acquired through 60 min, resulting in “tumor” max / background ratios from 16 to 8. Results: The method failed to identify heterogeneity at 30% error level in case of the 4 smallest simulated rings (r=2⋯8 pixels), and at 10% error level just the smallest one; the rest showed significant departure from homogeneity. All but the smallest sphere resulted in p>0.05 (keeping the

hypothesis of homogeneity). The tumor-to-background ratio from the model showed degraded contrast recovery only for the 2 smallest spheres. The heterogeneous phantom showed strongly significant heterogeneity at all contrast levels. Discussion: Our model tests object heterogeneity separately from partial volume effect and noise; thus it should be applicable to smaller objects than direct measures of region variance. An additional benefit is a robust estimation of tumor activity level, offering an objective parameter for follow-up studies.

Relationship Between Coronary Artery Calcium Score and Coronary Flow Reserve in Patients Evaluated for Coronary Artery Disease: a Hybrid Rb-82 PET/CT Imaging Study

E. Zampella[1], P. Arumugam[2], R. Assante[1], D. Tout[2], V. Gaudieri[1], C. Nappi[1], T. Mannarino[1], M. Panico[3], S. Daniele[3], W. Acampa[3], M. Petretta[4], C. Tonge[2], A. Cuocolo[1]; [1]Department of Advanced Biomedical Sciences, University of Naples Federico II, Naples, ITALY, [2]Nuclear Medicine Centre, Central Manchester University Teaching Hospitals, Manchester, UNITED KINGDOM, [3]Institute of Biostructure and Bioimaging, National Council of Research, Naples, ITALY, [4]Department of Translational Medical Sciences, University of Naples 'Federico II', Naples, ITALY.

Aim: Limited data are available on the value of coronary artery calcium (CAC) to predict myocardial blood flow (MBF) impairment and coronary vasodilator dysfunction. We assessed the relationship between CAC score, hyperemic MBF and coronary flow reserve (CFR) in patients without known coronary artery disease (CAD) undergoing hybrid Rb-82 PET/CT imaging. Materials and Methods: We evaluated 637 (age 58±13 years) consecutive patients without a documented history of CAD referred to myocardial perfusion imaging due to presence of multiple cardiac risk factors or risk assessment before general surgery. All patients were studied by vasodilator stress Rb-82 PET/CT and CAC scoring. The CAC score was measured according to the Agatston method. Resting and hyperemic MBF and CFR were automatically quantified. Patients were stratified into four groups based on their CAC score (0, 0.01-99.9, 100-399.9 and ≥400). Perfusion measurements were compared across levels of CAC score using one-way analysis of variance (ANOVA). The Spearman correlation coefficient was assessed between continuous CAC score and MBF or CFR. Univariable and multivariable logistic regression analyses were used to determine the variables associated with reduced (<2) CFR. Results: Patients had a global resting MBF of 1.18±0.39 ml/min/g. During hyperemia, MBF increased to 2.74±0.80 ml/min/g ($p<0.001$ vs. resting). CFR averaged 2.46 ±0.73. CAC score was 0 in 305 (46%) patients. Of those with CAC >0, the score was 0.01-99.9, 100-399.9 and ≥400 in 21%, 15% and 18% of patients, respectively. Global CAC score showed significant inverse correlation with hyperemic MBF and CFR (both $p<0.001$). No correlation was found between CAC score and baseline MBF ($p=0.611$). At ANOVA, among the four CAC groups, hyperemic MBF (2.97, 2.69, 2.74 and 2.23 ml/min/g) and CFR (2.67, 2.44, 2.38 and 2.00) significantly decreased (both $p<0.001$) with increasing CAC levels. Differently, a comparable global resting MBF among the four CAC groups was observed ($p=0.287$). At univariable analysis age ($p<0.001$), diabetes ($p<0.001$), family history of CAD ($p<0.05$), hypertension ($p<0.05$) and CAC score ($p<0.001$) displayed an inverse relationship with CFR. At multivariable analysis only age ($p<0.001$), diabetes ($p<0.001$) and CAC score ($p<0.05$) were independently associated with reduced CFR. Conclusions: In patients without known CAD there is a significant relationship between hyperemic MBF and CFR, and the extent of CAC. Noteworthy, diabetes and CAC score independently predict a CFR reduction. These results suggest that CAC score provides incremental information about CFR over established CAD risk factors in patients with suspected CAD.

OP121

Low-dose relative and quantitative myocardial blood flow imaging using 82Rb-PET

C. M. Hoff, E. Dul, L. P. Tolbod, H. J. Harms, K. Bouchelouche, J. Frøkiær, J. Sørensen; Aarhus University Hospital, Department of Nuclear Medicine & PET-Centre, Aarhus, DENMARK.

Aim: Relative and absolute measures of myocardial blood flow (MBF) are derived from a single 82Rb PET/CT scan using list mode data to extract static, gated and dynamic PET series. However, due to the short half-life of 82Rb (76s), high doses of 82Rb (>1100 MBq) are used in order to maximize image quality of the static images. Such high doses challenge scanner dead time performance and require a large eluate volume (20-40 mL) to be infused into the patient. The aim of the current study was to examine MBF with a low dose (LD) 82Rb protocol compared to the institution's standard

higher dose (HD) protocol.Methods: Nineteen patients referred to 82Rb PET were included in the study. Patients were examined during rest and stress with repeated LD and HD dose Rb-PET. We excluded four patients due to motion artifacts. Mean HD dose was 1137 MBq (range 1065-1187 MBq) and mean LD dose 347 MBq (range 269-449 MBq). Regional and global rest and stress MBF values, total perfusion deficit (TPD), ejection fraction (EF) and %-perfusion using the 5-segment model were calculated using commercially available software QPET (Cedars Sinai).Results: Mean segmental MBF (±SD) at rest was 1.09±0.32 and 1.18±0.30 mL/g/min, p=0.001 at LD and HD, respectively. At stress MBF was 2.30±1.00 and 2.48±1.17 mL/g/min, p=0.0007 at LD and HD, respectively. There was good correlation between LD and HD segmental MBF (LD=0.85xHD+0.14, R2=0.9, p<0.001). Mean global MBF at rest was 1.09±0.29 and 1.18±0.28 mL/g/min, p=0.14 at LD and HD, and at stress 2.26±0.96 and 2.43±1.14 mL/g/min, p=0.08 at LD and HD, respectively. Again good correlation between LD and HD global MBF. (LD=0.86xHD+ 0.13, R^2=0.9, p=0.02).Mean TPD with HD patients was 1.86±2.57% and 2.44±2.71% with LD patients. Correlation between LD and HD TPD was LD=0.92xHD+0.73, R2=0.77, p=<0.0001. Mean percentage perfusion with HD was 75.4±7% and 71.7±7.6% with LD patients. Correlation between LD and HD %-perfusion was LD=0.90xHD+3.79, R^2=0.69, p<0.0001. Mean EF with HD patients was 65±10% and 61±11% in LD patients with a good correlation. (LD=0.93xHD+0.85, R2=0,76, p=0,001).Conclusion: Excellent correlation between reduced dose and standard dose was found for absolute MBF. Correlation was still good for EF, TPD and %perfusion with LD being roughly 1/3 of the institutions standard dose. However, due to the increased image noise at LD, relative measures exhibited more scatter, potentially decreasing sensitivity.

OP122

Attenuated Coronary Flow Reserve Early after Implantation of a Bioresorbable Vascular Scaffold: one-month results of the VANISH-trial

W. Stuijfzand, R. Driessen, P. Raijmakers, A. Lammertsma, A. van Rossum, Y. Appelman, J. Lemkes, M. van Leeuwen, N. van Royen, P. Knaapen; VU University Medical Center, Amsterdam, NETHERLANDS.

Background: The bioresorbable vascular scaffold (BVS) may facilitate restoration of normal coronary physiology after resorption of the scaffold. Conversely, early after BVS implantation the mean luminal area is decreased in comparison with conventional metal stents due to bigger strut thickness which may impact coronary flow reserve (CFR). Therefore, a randomised clinical trial of BVS vs. metal drug eluting stent (DES) was initiated, utilizing positron emission tomography (PET) perfusion imaging to assess (hyperemic) myocardial blood flow (MBF) and CFR over a three year period (VANISH-trial). These are the one-month results of the ongoing VANISH-trial to investigate MBF and CFR early after BVS vs. DES implantation. Methods: Sixty patients (45 men (75%), 55 ± 7 years) with a documented single vessel type A or B1 lesion, either stable or unstable angina without biochemical signs of myocardial infarction, were included in this single blind randomized clinical trial. Patients were randomized to implantation of a DES or BVS (Xience Prime or ABSORB, respectively) in a one-to-one fashion. Approximately 1 month after percutaneous coronary intervention patients underwent $H_2{}^{15}O$ PET to assess (hyperemic) MBF and CFR. Results: Lesions were predominantly located in the LAD (n=36, 60%) and less frequently in the RCA (n=14, 23%) or Cx (n=10, 17%). One patient refused PET perfusion at 1 month follow-up (DES arm). Mean rest and hyperemic MBF of the treated vascular territory were 0.99 ± 0.26 and 3.18 ± 0.79 $mL{\cdot}min^{-1}{\cdot}g^{-1}$, respectively. MBF of the treated myocardial territory during rest and hyperemia of DES was comparable with the BVS arm (0.96 ± 0.24 vs. 1.02 ± 0.28 $mL{\cdot}min^{-1}{\cdot}g^{-1}$, p=0.38, and 3.33 ± 0.77 vs. 3.04 ± 0.80 $mL{\cdot}min^{-1}{\cdot}g^{-1}$, p=0.16, respectively). CFR of the treated territory was significantly lower in the BVS arm compared to DES (3.09 ± 0.94 vs. 3.57 ± 0.85, p<0.05). No differences in (hyperemic) MBF and CFR were documented in remote areas between treatment arms. Conclusions: CFR is slightly attenuated one month after implantation of a BVS compared with a DES, which may be related to the increased dimensions of bioresorbable scaffold material as compared with metal.

OP123

Measurement of left ventricular volumes and function using oxygen-15 labelled water gated positron emission tomography: comparison with cardiovascular magnetic resonance imaging

R. S. Driessen, J. Van Timmeren, W. J. Stuijfzand, M. T. Rijnierse, I. Danad, P. G. Raijmakers, A. M. Beek, A. C. Van Rossum, A. A. Lammertsma, H. J. Harms, M. C. Huisman, P. Knaapen; VU University Medical Center, Amsterdam, NETHERLANDS.

Measurement of left ventricular volumes and function using oxygen-15 labelled water gated positron emission tomography: comparison with cardiovascular magnetic resonance

imagingBackground: Positron emission tomography (PET) myocardial perfusion imaging is used for the diagnosis of coronary artery disease (CAD). Diagnostic and prognostic information, however, benefits from an assessment of left ventricular (LV) volumes and function. Recent developments in PET technology have fulfilled the prerequisites for [^{15}O]H_2O PET-derived LV function and dimensions. The aim of this study was to explore the feasibility of evaluating LV function by [^{15}O]H_2O PET using cardiovascular magnetic resonance imaging (CMR) as the reference technique.Materials and methods: Fifty-seven subjects with a varying degree of LV volumes and function were studied. LV end-diastolic volume (LVEDV), LV end-systolic volume (LVESV), and LV ejection fraction (LVEF) were assessed using both ECG-gated first-pass dynamic [^{15}O]H_2O PET and CMR. Intraclass correlation coefficients (ICC) were determined for intraobserver and interobserver variabilities.Results: PET derived LVEDV was comparable with CMR (206 ± 71 vs. 212 ± 68 mL, respectively; P = 0.13). However, LVESV was lower for PET (113 ± 67 vs. 127 ± 70 mL; P < 0.01), resulting in a higher LVEF (49 ± 14 vs. 44 ± 14%; P < 0.01). Correlations between PET and CMR for LVEDV, LVESV, and LVEF were 0.93, 0.91, and 0.87, respectively (P < 0.01 for all). Interobserver ICC for LVEDV, LVESV and LVEF was 0.97, 0.97 and 0.91, respectively. Intraobserver ICC was 0.99, 0.98 and 0.85 for LVEDV, LVESV and LVEF, respectively.Conclusion: It is feasible to assess cardiac functional data using gated dynamic [^{15}O]H_2O PET within the context of a routine quantitative myocardial perfusion study, without increasing radiation exposure or study duration. Good correlations with CMR and excellent reproducibility were found across a widerange of LV volumes and functions. However, PET slightly underestimated LVESV, yielding an augmented LVEF as compared with CMR.

OP124

Gated PET-measured cardiac synchrony correlates with QRS duration.

L. Juárez-Orozco[1], R. H. J. A. Slart[1], R. A. Tio[1], H. Boersma[1], R. A. Dierckx[1], A. Gonzalez-Monroy[1], F. Iñarra-Talboy[2], E. Alexanderson[2]; [1]University Medical Center Groningen, Groningen, NETHERLANDS, [2]Instituto Nacional de Cardiología "Ignacio Chávez", Mexico City, MEXICO.

BACKGROUND: Gated PET myocardial perfusion represents a modern technique with state-of-the-art software for assessment of stress myocardial blood flow (sMBF) and perfusion reserve (MPR). Additionally, it offers the possibility to evaluate ventricular mechanical synchrony of contraction through the Entropy (E) measurement. Interestingly, synchrony has been previously studied although no current gold standard technique is available. The standard 12-derivation EKG is considered useful to assess ventricular electrical synchrony through the evaluation of the QRS complex. Its prolongation (>120ms) has been considered in as criteria for guiding resynchronization therapy. The present study aims to evaluate the relationship between PET-derived ventricular E and the EKG-measured QRS duration when sMBF and traditional cardiovascular risk factors are taken into account. METHODS: We retrospectively included 70 patients (54% males) who underwent a rest and adenosine stress dynamic and 8-frame gated 13N-ammonia PET scan without prior history of myocardial infarction. A standard 12-lead resting EKG was acquired for every patient at the time of the scan. Demographic variables included gender, age, hypertension, type 2 diabetes mellitus, dyslipidemia and smoking. MPR was calculated as the ratio between sMBF and rest myocardial blood flow. Entropy was expressed as a percentage inversely proportional to the uniformity of the ventricular contraction. The QRS complex duration as the dependent variable was dichotomized as normal or prolonged (cutoff 120 ms) and analyzed with a multiple stepwise binary logistic regression model. Statistical analysis was performed using SPSSv.20. RESULTS: Our population had a mean age of 63±10 years. There were 68% of patients with hypertension, 60% with dyslipidemia, 14% with diabetes mellitus and 54% with family history of cardiovascular disease. We documented a mean sMBF=2.09±0.64, mean MPR=2.65±0.83 and mean E=43.8±8.9%. The logistic regression showed Entropy as a significant predictor for an enlarged QRS complex (b=0.116 SE=0.050, OR=1.123 95% [1.018, 1.239], p=0.020). CONCLUSION: Gated PET derived phase Entropy, as a measure for ventricular synchrony, is related to the finding of a prolonged QRS complex in the standard EKG when sMBF and coronary risk factors are taken into account. This suggests that PET derived mechanical synchrony assessment may be useful in further risk stratification. Further research into its role for therapeutic is selection needed.

OP125

Stress-induced Systolic Dysfunction and Subendocardial Ischemia in Left Ventricular Hypertrophy Patients With Preserved Maximal Blood Flow in Ammonia PET

R. Sciagra, H. Castagnoli, F. Cipollini, R. Calabretta, S. Passantino, I. Olivotto; University of Florence, FLORENCE, ITALY.

Aim: Left ventricular (LV) ejection fraction (EF) decrease in stress gated PET reveals ischemia. Patients with hypertrophic cardiomyopathy (HCM) have abnormalities in myocardial blood flow (MBF) due to microvascular dysfunction, but whether these cause ischemia is uncertain. Owing to increased wall thickness, subendocardial ischemia has been suspected, but this could remain undetected if epicardial MBF is

maintained. We assessed whether there is a relationship between LVEF decrease and abnormalities in subendocardial MBF despite preserved maximal MBF in LV hypertrophy patients.Materials and Methods: We studied 15 LV hypertrophy (maximum wall thickness 17 ± 5 mm) patients undergoing rest and stress (dipyridamole) 13NH3 gated PET because of suspected HCM. Gated PET images were analyzed using QGS, MBF was assessed using the PCARD module of PMOD software and a 17 segments scheme. Segmental endocardial and epicardial MBF were evaluated using 13NH3 parametric mapping. Transmural perfusion gradient (TPG) was defined as endocardial MBF/epicardial MBF.Results: In all patients stress MBF was > 1.85 mL/min/g tissue and myocardial flow reserve > 2.5. There were 10 patients with unchanged or increased LVEF after stress (G 1), and 5 with LVEF decrease (G 2). Entire wall resting and stress MBF were not different between the two groups (rest G 1: 0.85 ± 0.22 vs. rest G 2: 0.89 ± 0.11; stress G 1: 2.72 ± 0.46 vs. stress G 2: 2.65 ± 0.54; all NS), so resting endocardial (G 1: 0.83 ± 0.23 vs. G 2: 0.80 ± 0.11; NS) and epicardial MBF (G 1: 0.67 ± 0.24 vs. G 2: 0.64 ± 0.17; NS), and resting TPG (G 1: 1.31 ± 0.26 vs. G 2: 1.32 ± 0.28; NS). Under stress, epicardial MBF remained comparable (G 1: 1.79 ± 0.56 vs. G 2: 1.82 ± 0.59, NS), but endocardial MBF was lower in G 2 (G 1: 2.26 ± 0.66 vs. G 2: 2.03 ± 0.40, $p < 0.0001$) and TPG became significantly different: G1: 1.36 ± 0.36 vs. G 2: 1.22 ± 0.42, $p < 0.02$. The proportion of segments with lower endocardial than epicardial MBF under stress was significantly higher within G 2 than within G 1 patients (36% vs. 16%, $p< 0.001$).Conclusion: In patients with LV hypertrophy suspected of HCM, but with apparently preserved stress MBF, an abnormal LVEF response in stress gated PET was accompanied by decreased stress endocardial MBF, a finding that supports the notion of isolated subendocardial ischemia.

OP126

AQUA-5: Four Software Tools for 15O-Water PET Myocardial Perfusion Quantification Exhibit Good Intraobserver Reproducibility

S. V. Nesterov[1,2], K. Yoshinaga[3], Y. Tomiyama[3], C. Han[1], R. Sciagrà[4], V. Berti[4], P. Knappen[5], I. Danad[5], J. M. Knuuti[1]; [1]Turku PET Centre, Turku, FINLAND, [2]Institute of Evolutionary Biochemistry and Physiology, RAS, St. Petersburg, RUSSIAN FEDERATION, [3]Hokkaido University Graduate School of Medicine, Sapporo, JAPAN, [4]Nuclear Medicine Unit of the University of Florence, Florence, ITALY, [5]Departments of Nuclear Medicine and PET Research, of VU University Medical Center, Amsterdam, NETHERLANDS.

AIM. 15O-labelled water is considered the gold standard for myocardial blood flow (MBF) quantification with PET. Several software tools (SW) enable the quantification; however, there are still no exhaustive cross-comparison studies for these SW, needed to standardize the approach. In the AQUA-5 project, we aimed to investigate several clinically important issues, and as an initial step, we aimed to evaluate the intraobserver reproducibility of MBF and myocardial flow reserve (MFR) using existing SW. METHODS. Five tools-Carimas, CardiacVUer, HOQUTO, PMOD, and Siemens In-House Software-were studied using dynamic PET scans (a hybrid 64-row Discovery VCT PET/CT scanner) from 91 clinical patients. 15O-labelled water (900-1100 MBq) was injected at rest; a stress scan was performed using adenosine (140μg/kg/min). Experts used one of the tools each to analyze global and regional (LAD, LCx and RCA) MBF and MFR twice with at least one week interval. We applied a custom linear mixed model for the repeated measures to produce the two agreement metrics-intraclass correlation coefficient (ICC) and difference between the values from the models-calculated pairwise. Differences below 20% of median values with corresponding ICCs above 0.75 witnessed to good reproducibility. RESULTS. MBF-rest and stress-was measured in mL/min/g, MFR and ICC were unitless. CARIMAS. Global rest MBF (rMBF) - 0.00±0.07, ICC=0.95; stress MBF (sMBF) - 0.04±0.37, ICC=0.94; MFR - 0.05±0.38, ICC=0.91. Regional rMBF values ranged from 0.01±0.06 to 0.01±0.12, ICC: 0.90-0.97; regional sMBF: 0.01±0.45-0.13±0.41, ICC: 0.92-0.94. Regional MFR: 0.01±0.47-0.10±0.39, ICC: 0.85-0.93. CARDIAC VUER. Global rMBF - 0.00±0.05, ICC=0.97; sMBF - 0.01±0.15, ICC=0.98; MFR - 0.00 ±0.21, ICC=0.96. Regional rMBF: 0.00±0.06-0.01±0.05, all ICC values were 0.97; regional sMBF: 0.00±0.19-0.02±0.17, ICC: 0.97-0.98. Regional MFR: 0.00±0.21-0.01±0.24, ICC: 0.95-0.96. HOQUTO: Global rMBF - 0.05±0.31, ICC=0.66; sMBF - 0.18±0.97, ICC=0.58; MFR - 0.01±0.95, ICC=0.96. Regional rMBF: 0.05 ±0.34-0.96±8.56, ICC: 0.00-0.69; regional sMBF: 0.04 ±1.33-0.18±1.27, ICC: 0.56-0.67. Regional MFR: 0.02 ±1.10-0.15± 1.38, ICC: 0.46-0.54. PMOD: Global rMBF - 0.00±0.07, ICC=0.97; sMBF - 0.09±0.46, ICC=0.83; MFR - 0.04±0.38, ICC=0.90. Regional rMBF: 0.00 ±0.08-0.01±0.09, ICC: 0.94-0.98; regional sMBF: 0.06 ±0.43-0.11±0.55, ICC: 0.81-0.89. Regional MFR: 0.00 ±0.40-0.06± 0.45, ICC: 0.88-0.90. SIEMENS IN-HOUSE SW: Global rMBF - 0.09±0.15, ICC=0.85; sMBF - 0.02±0.29, ICC=0.94; MFR - 0.15±0.36, ICC=0.93. Regional rMBF: 0.04±0.08-0.11±0.18, ICC: 0.81-0.95; regional sMBF: 0.01±0.32-0.03±0.32, ICC: 0.93-0.96. Regional MFR: 0.10±0.36-0.17± 0.40, ICC: 0.93-0.94. CONCLUSION. The intraobserver reproducibility was good in four out of the five studied tools for measuring MBF with 15O-water PET.

Spill-over effect of radioactivity from right ventricular cavity on septum in cardiac PET ^{15}O-water study

C. Han; Turku University Central Hospital and University of Turku, TURKU, FINLAND.

Purpose: In heart, ventricular septum separates the left and right ventricles(LV and RV), implying that the spill-over effects from both sides should be considered in PET studies. However, in cardiac PET perfusion analysis, the effect from right ventricular radioactivity is not always corrected, leading the loss of accuracy of modelling results in septum. This study investigates the bias in perfusion estimation without RV spill-over correction, based on human 15O-water studies and simulated data.Methods: Two 1-tissue compartment models for ^{15}O-water study(Iida et al. 1989), with and without RV spill-over correction (LV Model and LV_RV Model), have been implemented in Carimas (a PET data analysis package developed in Turku PET Centre, Finland http://www.turkupetcentre.fi/carimas). In simulation study, time-active curves (TAC) from left (LV) and right ventricular cavities were taken from typical ^{15}O-labelled water clinical studies. In LV_RV Model, the myocardial ROI TAC was expressed as: ROI(t)=Va_lv*LV(t)+Va_rv*RV(t)+alpha*C(t), where Va_lv and Va_rv are spill-over fractions from LV and RV, respectively, and alpha is perfusable tissue fraction. 100 ^{15}O-water PET perfusion patient data were analyzed using two models.Results: In patient data, septal perfusion was found to be reduced 17.3% without RV spill-over correction, meanwhile, lateral segments had very slight effect by RV radioactivity (0.9%). In simulation study, RV was found to affect significantly the perfusion estimation and this effect becomes bigger for higher perfusion values and larger Va_rv. When ground values of Va_rv=0.1, 0.15, 0.2, 0.25ml/ml, for ground flow value of 0.98 ml/g/min (as rest condition), estimated flow values with LVModel were 0.94(-13%), 0.85(-20%), 0.78(-27%) and 0.72(-33%) ml/g/min, respectively; for ground flow value of 3.2 ml/g/min (as stress condition), estimated values with LVModel were 2.66(-17%), 2.34(-27%), 2.07(-36%) and 1.84(-43%) ml/g/min, respectively. Meanwhile, estimated flow values from LV_RVModel were very close to ground values (error<2%).Conclusions: Based on patient data and simulation, this study confirms that spill-over effect from RV leads to severe underestimation of perfusion in septum, unless correction is applied in the analysis tool.

Do.MoRe: Treatment of Bone Metastases

OP134

Optimization of imaging following 223Ra administration in targeted alpha-emitting radionuclide therapy of bone metastases.

N. Benabdallah[1], M. Bernardini[2], C. de Labriolle Vaylet[3], D. Franck[1], A. Desbrée[1]; [1]IRSN, Fontenay aux Roses, FRANCE, [2]Hôpital Européen George Pompidou, Paris, FRANCE, [3]Hôpital Trousseau, Paris, FRANCE.

Purpose: With a growing demand of alpha-emitting radiopharmaceuticals, especially Xofigo® (223RaCl2) which is used in the treatment of metastatic bone disease, the optimization of dosimetry becomes necessary.

Indeed, in Europe, as stated on the council directive 2013/59/euratom, exposures of target volumes for radiotherapeutic purposes shall be individually planned taking into account that doses to non-target volumes and tissues shall be as low as reasonably achievable. To personalize the dosimetry, patient images shall be used. Nevertheless, less than 2% of the 223Ra emissions are from photons. Therefore, the purpose of this study was then to investigate the possibility of imaging 223Ra. Methods: The experiments were conducted at the Hopital Européen Georges Pompidou with an Infinia Hawkeye 4 gamma camera, equipped with a medium-energy collimator. Imaging parameters, such as sensibility, spatial resolution and energy spectrum, were determined using several physical phantoms with a source of 6 MBq of 223Ra. Bone metastases were modeled with a NEMA Body Phantom to investigate image degradation based on the concentration of 223Ra. Results: The acquired energy spectrum allowed to visualize several photon peaks: at 85, 154 and 270 keV. Camera sensitivity measured from the phantom study was 102.3 cps/MBq for the 85 keV ± 20 %, 89.9 cps/MBq for the 154 ± 20 % window and 65.4 cps/MBq for the 270 ± 10 % window. The spatial resolution (full-width at half-maximum) was respectively 1.7, 1.9 and 1.8 cm for the three energy windows. SPECT/CT images of NEMA Body Phantom without and with attenuation have permitted to determine the best reconstruction parameters. Conclusion: This study has demonstrated that it is possible to obtain clinically relevant information from images of 223Ra. All these results will be valuable to analyze biodistribution imaging of the radiopharmaceutical in the patient body and go further in the reconstruction of patient images in order to personalize the dosimetry.

OP135

Progress of blood capacity under Radium-223 treatment

C. Körber, N. Körber-Hafner; Nuclear Medicine Fulda, Fulda, GERMANY.

AIM OF STUDY: Since some months Radium-223 (Xofigo, Bayer Pharma AG, Berlin, Germany) is a rationale for the treatment of castration-resistent metastatic prostate cancer (1) The relevance of the irradiation on blood building is not yet well investigated and could be a reason for the decline of blood cells. We therefore investigated this effect on the blood levels under therapy. METHOD: We have treated 10 patients so far and investigated the blood levels of erythyrocytes, leucocytes and thrombocytes under therapy, at the beginning and the end of Radium-223 infusion as well as in all cycles of injection. We compared the blood levels according to the level at the start point. Furthermore other possible side effects we evaluated. Statistical analyses were conducted with Statistica 10.0 (StatSoft). Two-tailed P values of less than 0,05 were considered to indicate statistical significance. RESULTS: The time interval of investigation was between February 2014 and February 2015. No severe side effects as nausea or vomiting could be ruled out. The levels of leucocytes reduced between injection 1 and 2 (mean ± SD) 5,6 to 4,6 ($p<0,08$), between injection 1 and 3 $p<0,1$, between injection 1 and 4 $p<0,01$, between injection 1 and 5 $p<0,13$, between injection 1 and 6 $p<0,3$. Similar results were found for the parameters of erythrocytes and thrombocytes, revealing a significant decline of blood cells between injection 1 and 4, but no significant reduction of the blood building capacity regarding injection 1 and 6. DISCUSSION: The treatment of castration-resistent metastatic prostate cancer is a save treatment option without severe side effects as shown. The reduction of the blood building regarding erythrocytes, leucocytes and thrombocytes are only significant between the injection 1 and 4, but the blood levels from start and end point after 6 injections show no significant reduction. No participant of the treatment group had to be excluded. Literature: Parker C. et al., Alpha Emitter Radium-223 and survival in metastatic prostate caner, N Engl J Med 2013;369:213-223.

OP136

Feasibility and efficacy of 223Ra-dichloride in treatment of bone metastases in patients with castration-refractory prostate cancer (mCRPC)

s. mazzarri[1], G. Boni[1], E. Borsò[2], L. Galli[3], A. Farnesi[4], F. Betti[1], L. Antonacci[1], A. Traino[5], S. Ricci[4], D. Volterrani[1]; [1]Regional Center Of Nuclear Medicine, University Hospital Of Pisa, pisa, ITALY, [2]Division of Nuclear Medicine, Sant'Andrea Hospital of La Spezia, La Spezia, ITALY, [3]Oncology Division, University Hospital of Pisa, pisa, ITALY, [4]Oncology Division,University Hospital of Pisa, pisa, ITALY, [5]Health Physics Unit, Section of Medical Physics, University Hospital, Pisa, Italy, pisa, ITALY.

Aim: To present the Tuscany single-centre experience about the employing of the novel therapeutic radiopharmaceutical 223Ra-dichloride in the treatment planning of patients with mCRPC. Method:Thirteen patients were treated from August 2013 to date. Five patients have been enrolled in the Bayer Clinical Study 16216 and 8 have been treated as routine application. Patients (age 67±8.4 yrs, median PSA 149.5 ng/mL, excluding one case of neuroendocrine differentiation) received 223Ra-dichloride 50 kBq/kg i.v. on day 1 every 28 days for a maximum of 6 cycles. Pre-treatment evaluations were made using CT in order to exclude visceral metastases, and bone scan. Patients have been evaluated at every cycle with

complete blood chemistry (including serum ALP, PSA and LDH), pain VAS score, quality of life questionnaire (FACT-p), and analgesic consumption. The last group of patients started the cure in March 2015. Results: At the current time-point 13 patients received 72 cycles of 223Ra-dichloride. No problems in vial manipulation, dose preparation and administration occurred. A multidisciplinary team has followed patients during both screening and treatment period. Only 3 cycles have been delayed (2 due to blood toxicity, 1 due to drug's manufacturing hitches) and 3 patients discontinued the treatment (2 because of non reversible blood toxicity and anorexia, and 1 because of hepatic disease progression). Regarding valuable clinical data, bone marrow toxicity resulted in G3 anemia in 2 patients, G2 neutropenia in 2 patients, and G1 thrombocytopenia in 1 patient. Anorexia G3 occurred in 3 patients, while no case of diarrhoea was observed. Biomarkers response showed median ALP decline of -50% and median LDH decline of -5%. We observed mean PSA decline of -15%. One patient who presented with superscan at baseline received 223Ra-dichloride 5 cycles before hepatic progression, showing ALP levels decline of -89%, LDH -44% and PSA -48%. According to VAS score and FACT-p, most of patients had bone pain relief and reduced pain drugs intake. Conclusion: Single-centre experience shows the feasibility and efficacy of radiometabolic therapy with 223Radium-dichloride in patients with mCRPC. Multidisciplinary careful evaluation of bone marrow toxicity and gastrointestinal adverse events must be carried out to optimize individual compliance. Palliative effect allows decreasing pain drugs consume. The mild toxicity could permit the use of 223Ra- dichloride in combination with other treatments.

OP137

Metastatic control probability in patients with prostate cancer metastatic to bone treated ^{186}Re-HEDP

A. M. Denis-Bacelar[1], A. Divoli[2], S. Chittenden[2], Y. Du[2], G. D. Flux[2]; [1]Institute of Cancer Research, London, UNITED KINGDOM, [2]Royal Marsden Hospital, London, UNITED KINGDOM.

Aim: The metastatic control probability model can be used to estimate the impact of relevant factors on response to treatment. Disease burden is of particular interest in patients with castration-resistant prostate cancer (CRPC) metastatic to bone, where the number and volume of bone lesions varies for each patient. The aim of this study was to determine the metastatic absorbed dose necessary to obtain a metastatic control probability of 0.9 in patients treated with molecular radiotherapy. Materials and Methods: A cohort of 22 patients treated with 5 GBq of ^{186}Re-HEDP from a phase II clinical trial was considered. Absorbed dose distributions were obtained using the Qrius^{TM} dosimetry toolkit from quantified co-registered sequential SPECT scans of the thorax and pelvis. Bone lesions were outlined using volume-dependent thresholds obtained from phantom studies. Tumour control probabilities (TCP) and biological effective doses (BED) were calculated for each lesion using the linear-quadratic model. Radiobiological parameters for prostate cancer cells of α=0.12, α/β=1.5, clonogenic cell density of 10^7 cm^{-3} and a repair half-time of 1.5 h were assumed for all patients. The metastatic control probability (MCP) was determined as the product of the TCP to each lesion. The metastatic absorbed dose (the mean of the absorbed doses delivered to all lesions) necessary to achieve an MCP of 0.9 was then determined from the delivered absorbed dose distribution. Results: A total of 379 metastatic bone lesions were outlined, with a median of 11 per patient. The mean total volume of lesions was 228 ml (range 17 - 913 ml). The mean lesion volume per patient ranged from 6 ml to 57 ml. The range of metastatic absorbed doses delivered was 8 - 32 Gy. The metastatic absorbed dose to obtain an MCP of 0.9 ranged from 93 Gy to 589 Gy (mean 219 Gy). Conclusion: Preliminary results show that the metastatic absorbed doses required to achieve a high metastatic cure probability changes significantly within the patient cohort studied. This indicates the effect of the heterogeneous distribution of absorbed doses delivered to multiple lesions, whereby the MCP is heavily influenced by lesions with the lowest uptake.

OP138

A DOTA conjugated Zoledronic acid derivative: A novel bone targeting theranostic compound

M. Meckel[1], R. Bergmann[2], W. Mohnike[3], M. Miederer[4], F. Roesch[1]; [1]University of Mainz, Mainz, GERMANY, [2]Helmholtz Zentrum, Dresden-Rossendorf, GERMANY, [3]Diagnostisch Therapeutisches Zentrum, Berlin, GERMANY, [4]University Hospital, Mainz, GERMANY.

Aim of the study: Zoledronic acid proofed to have a high affinity to calcified tissues and is commonly used in the treatment of osteoporosis and bone metastases. A conjugate of zoledronic acid with a macrocyclic chelator, labeled with ^{68}Ga and ^{177}Lu, opens new possibilities in bone targeted radionuclide imaging and therapy. Endoradiotheraphy with ^{177}Lu-labelled macrocyclic bisphosphonates could have great potential subsequent to PET examinations utilized with ^{68}Ga-labelled analogous in the treatment of painful skeletal metastases, following the *theranostics* concept. Methods: We synthesized a DOTA zoledronic acid conjugate (DOTAM^{ZOL}) and labelled it with the PET-nuclide ^{68}Ga, and the therapy nuclide ^{177}Lu. The new bone targeting compound was evaluated in *in vivo* small animal PET and SPECT and in *ex vivo* organ distribution studies against [^{18}F]NaF, ^{223}RaCl$_2$ and other

DOTA bisphosphonates in healthy Wistar rats, followed by first human applications in metastatic patients. Results: The new ligands reached a RCY of 80 to 90% in 15 min with ^{68}Ga. After resin purification the purity of the [^{68}Ga]DOTAM^{ZOL} was higher than 98%. The tracers showed low uptake in soft tissue, a fast renal clearance and a high accumulation in bone (SUV_{Femur} = 5.4±0.6). Labelling with ^{177}Lu resulted in quantitative yields. [^{177}Lu]DOTAM^{ZOL} showed a superior target to background ratio compared to $^{223}RaCl_2$. First applications in bone metastatic patients revealed high accumulation in metastatic lesions. Conclusions: The novel bone targeting compound DOTAM^{ZOL} showed a promising uptake profile and a high target to background ratio. The *theranostic* approach seems to be a promising concept for the management of bone metastases in future.

OP139

Dosimetry Results of Lu-177-DKFZ-PSMA-617 Treatment in Castration Resistant Prostate Cancer Patients

N. Yeyin[1], A. Mohammad[1], **L. Kabasakal**[1], E. Demirci[2], A. Aygun[1], M. Ocak[3], T. Toklu[4], H. Tanyildizi[1], N. Selcuk[4]; [1]Department of Nuclear Medicine, Cerrahpasa Medical Faculty, Istanbul University, istanbul, TURKEY, [2]Department of Nuclear Medicine, Sisli Etfal Training and Research Hospital, istanbul, TURKEY, [3]Department of Pharmaceutical Technology, Pharmacy Faculty, Istanbul University, istanbul, TURKEY, [4]Department of Nuclear Medicine, Yeditepe University Medical School, istanbul, TURKEY.

Aim: The unique expression of PSMA provides an excellent target for prostate cancer imaging and therapy using Ga-68 and Lu-177 labeled PSMA ligands. Lu-177-DKFZ-617 PSMA ligand seems to be a promising tracer for radionuclide therapy in patients with progressive prostate cancer. However, there are no published data regarding the radiation dose given to the normal tissues for the systemic therapy of Lu-177-DKFZ-617 PSMA ligand. The aim of the present study was to estimate the radiation doses in patients who underwent radiomethabolic therapy. Methods and materials : The study composed of 9 patients with progressive disease who underwent Lu-177 PSMA therapy with a mean age of 62 ±5.7 years. All patients had prior PSMA PET imaging and had intense tracer uptake at the lesions. Patients received a mean of 5.4±1.5 GBq, ranged from 3.3 GBq to 7.4 GBq Lu-177-PSMA. To evaluate bone marrow absorbed dose 2 cc blood samples were withdrawn in short variable times (3, 15, 30, 60, 180. minutes and 24, 48, 120. hours) after injection. Further more whole body images were obtained at 4, 24, 48 and 120 hour after injection and in order to quantify the activity taken up in the body, kidneys, liver, right parotid and left parotid, and over lesions. The geometric mean of anterior and posterior counts were determined through ROI analysis, after that background subtraction and attenuation correction were applied using patients Ga-68-PSMA PET/CT images taking into account. Organ thickness, body thickness and Hounsfield unites from Computed Tomography scan. OLINDA/EXM dosimetry program was used for curve fitting, residence time calculation and absorbed dose calculations. Results: Calculated absorbed dose of bone marrow, left kidney, right kidney, left parotid, right parotid and total body were 0.08±0.0.03, 2.12 ±0.66, 1.95±0.78, 2.88±1.83, 2.79±1.32, (Gy/3.7GBq) respectively. For the liver, left and right lacrimal glands and whole body radiation doses were 0.6±0.2, 6.2±3.9, 6.4±3.4 and 0.1 ±0.04 (Gy/3.7 GBq) respectively. The estimated lesion doses were ranged from 3.05 to 47.7 GY/3.7 GBq with a mean of 12.6±12.8 Gy/3.7GBq. Conclusions : Our first results suggested that Lu-177 DKFZ-PSMA-617 therapy is a safe method, which can be given in 3 to 4 cycles of 7.4 GBq. The target organ seems to be the parotid glands rather than kidneys and bone marrow. The lesion radiation doses are within acceptable ranges however there is a substantial individual variance so patient dosimetry seems to be mandatory.

OP140

Peptide Radioligand Therapy (PRLT) Using Lu-177 Labeled DOTAGA-PSMA Inhibitor Yields Objective Responses in Metastatic Castrate-resistant Prostate Cancer

H. R. Kulkarni[1], A. Singh[1], C. Schuchardt[1], I. Klette[1], H. J. Wester[2], R. P. Baum[1]; [1]THERANOSTICS Center for Molecular Radiotherapy and Molecular Imaging, Bad Berka, GERMANY, [2]Pharmaceutical Radiochemistry, Technical University Munich, Munich, GERMANY.

Aim: We present the first clinical results assessing objective response after therapy with Lu-177 DOTAGA-PSMA inhibitor (Lu-177 PSMA) in patients with metastatic castrate-resistant prostate cancer (mCRPC).Methods: Peptide radioligand therapy (PRLT) with Lu-177 PSMA was performed in 56 patients, administering a total of 131 cycles. Ga-68 PSMA PET/CT (contrast-enhanced CT scan) was used for patient selection as well as follow-up after 2 and 4 therapy cycles. The mean administered activity of Lu-177 PSMA per cycle was 5.7±0.8 GBq, median 5.8 GBq. Post-therapy response after 2 or 4 cycles could be assessed until now in 31 patients. The results were analyzed using a prospective patient database (338 items/patient).Results: According to molecular imaging criteria, partial remission was observed in 14 (44 %) patients, correlating with the fall in PSA after therapy. The disease remained stable in 7 (22 %) patients. Progressive disease after initial response was noted in 3 (9.6 %) patients.

Median time to progression after the first PRLT in initial responders was 13 months (range 4 - 11). Thus, the number of responders was 24/31 patients (78 %). 7 patients (22 %) with extensive metastastes did not respond to therapy and died with a median time of 10 months after the first therapy cycle. Morphological response (partial remission according to RECIST) was observed in 6 patients, and stable disease in 15 patients. All symptomatic patients reported significant improvement in pain and quality of life after therapy. The treatment was well tolerated by all patients without any significant adverse effects (especially no dry-eye-dry-mouth syndrome) or alterations in any of the laboratory parameters or of renal function (as determined by Tc-99m MAG3/TER and serial creatine and GFR measurements).Conclusion: Peptide radioligand therapy (PRLT) utilizing the small molecule Lu-177 DOTAGA-PSMA inhibitor is efficacious, not only in terms of symptomatic improvement, but also for reducing the tumor burden. PRLT was well tolerated in all patients, i.e., without hematological, salivary or renal toxicity.

OP141

Quantifying the Effect of Peptide Amount on the Biologically Effective Dose for Therapy using Lu-177 Labeled PSMA Ligands

P. Kletting[1], C. Schuchardt[2], H. Kulkarni[2], M. Sayeg[2], S. Wiesalla[2], G. Winter[1], A. Singh[2], R. Baum[2], A. Beer[1]; [1]Ulm University, Deparment of Nuclear Medicine, Ulm, GERMANY, [2]Zentralklinik Bad Berka, THERANOSTICS Center for Molecular Radiotherapy and Molecular Imaging (PET/CT), ENETS Center of Excellence, Bad Berka, GERMANY.

Peptide radioligand therapy (PRLT) using Lu-177 labeled PSMA ligands is a promising therapy option for patients with prostate cancer. The effect of peptide amount on the biodistribution and absorbed dose has been observed in animal studies and in patients [1-2] for PRLT, but was never systematically investigated and quantified for PSMA ligands. The aim of this work is to quantify the impact of PSMA peptide amount on the biologically effective dose (BED) for critical organs and the tumor using a physiologically based pharmacokinetic model. Methods: Included were 5 patients suffering from metastasized prostate cancer. The administered activity was 5.7±1.3 GBq (labelled with 160±16 μg) Lu-177 PSMA ligand. Based on 4-6 [0.5, 3, 24, 48, (72), 120 h] conjugated planar whole-body scans, time-dependent whole-body, organ and tumor activities were determined. A physiologically based pharmacokinetic (PBPK) model was developed using SAAM 2. Relevant biological mechanisms such as blood flow, transport in the interstitial space, specific binding, internalization, release of activity from cell and renal clearance were included in the model. The model parameters were fitted to the time activity data of the patients or were taken from the literature. For the simulation study the model was implemented in Matlab/Simulink. The degree of binding sites saturation and the BED of the tumor and critical organs were calculated using the estimated model parameters for different amounts of peptide. Results: The model describes the data well. Standard deviations and correlation matrixes are adequate. The estimated values for tumor perfusions (0.01-8 ml/g/min) and receptor concentrations (18-2200 nmol/L) showed high variation. However, kidney receptor concentrations (21±12 nmol/L) were in the same order of magnitude for all patiens. The simulation study using these parameters showed that for moderately or poorly perfused tumors small amounts of peptide led to considerably lower saturation of binding sites compared to kidney and salivary glands. Therefore, the BED for a moderately perfused tumor for a limiting kidney dose of 10 Gy was 2.3 -fold higher when increasing the amount from 16 nmol to 256 nmol. Conclusions: Saturation of binding sites in kidney and salivary glands is reached with considerably lower amounts of peptide than in many tumors. Therefore, optimizing the amount of peptide (or preloading) with PSMA ligands might considerably improve the ratio of tumor-to-salivary and tumor-to-kidney BED. [1] Kletting et al. 2012 Med. Phys. 18F-fluorodeoxyglucose PET/CT and Dynamic Contrast-Enhanced MRI as prognostic indicators in Malignant Pleural Mesothelioma (the SWAMP trial)

D. O. Hall[1], I. D. Lyburn[1], J. Searle[1], C. E. Hooper[2], N. A. Maskell[3]; [1]Cobalt Health, Cheltenham, UNITED KINGDOM, [2]Worcester Royal Hospital, Worcester, UNITED KINGDOM, [3]University of Bristol, Bristol, UNITED KINGDOM.

Aims: The South West Area Mesothelioma and Pemetrexed (SWAMP) trial was carried out to assess the role of various

biomarkers in monitoring treatment in Malignant Pleural Mesothelioma (MPM). This included ^{18}F-fluorodeoxyglucose positron emission tomography with computed tomography (FDG PET/CT) and dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI). This paper assesses the prognostic ability of baseline volumetric PET/CT and DCE-MRI. Materials and Methods: 73 patients were recruited, 58 received chemotherapy, 15 were included in the comparator arm. Patients had FDG PET/CT and DCE-MRI on the same day at a single institution. PET/CT studies were carried out on a Philips Gemini system, and DCE-MRI was carried out on a Philips Open MRI scanner. Follow up was for at least 12 months. The PET studies were assessed using volumetric analysis including all areas with SUV > 2.5. Metabolic Tumour Volume (MTV) was calculated. The DCE-MRI enhancement images were assessed, and an ROI was drawn at over a central tumour slice. The integrated area under the enhancement-time curve in the first 90s was calculated (IAUC90). Kaplan-Meier analysis was carried out for PET MTV and DCE-MRI IAUC90. Results and conclusions: Overall Survival (OS) was significantly longer for MTV below median than above ($p<0.001$), 481 days (IQR 266-709 days), compared with 266 days (IQR 177-456 days). OS was generally longer for IAUC90 below median than above, 458 days (IQR 233-689 days) compared with 274 days (IQR 204-498 days) though the difference wasn't significant at the 5% level ($p=0.08$). Adding IAUC90 to MTV gave no significant change in prognosis. Baseline FDG PET/CT was predictive of OS. Baseline DCE-MRI (iAUC90) was not predictive of OS. However, DCE-MRI results were promising, and would be worth further study.

OP144

Respiratory-gated FMISO-PET/CT detects tumor hypoxia with higher sensitivity in non-small cell lung cancer

S. Watanabe[1], **S. Okamoto**[1], T. Shiga[1], T. Inoue[2], K. Hirata[1], K. Magota[1], K. Nishijima[3], Y. Kuge[3], H. Shirato[2], N. Tamaki[1]; [1]Department of Nuclear Medicine, Hokkaido University Graduate School of Medicine, Sapporo, JAPAN, [2]Department of Radiation Medicine, Hokkaido University Graduate School of Medicine, Sapporo, JAPAN, [3]Central Institute of Isotope Science, Hokkaido University, Sapporo, JAPAN.

Objective: More appropriate therapeutic strategies are required for the tumor hypoxia evaluated by PET. However, respiratory motion during PET imaging introduces quantitative inaccuracies in non-small cell lung cancer (NSCLC). For the exact targeting to hypoxic area in NSCLC in radiation therapy, respiratory gating (RG) on the hypoxic PET may be a good tool. The aim of this study was to investigate the usefulness of RG on 18F-fluoromisonidazole (FMISO) PET image quantification for hypoxia. Methods: FMISO-PET/CT was performed in 13 patients with pretreatment NSCLC. PET images were scanned by integrated PET/CT scanner at 4 hours after FMISO injection. The respiratory signal was obtained using a pressure sensor integrated in an elastic belt placed around the patient's abdomen. The respiratory cycle was divided into 5 phases, corresponding to about 6 minute/phase accumulation in our protocol. We used the 3rd phase for analysis which is equivalent to expiration phase. Non-gating images (NG) were reconstructed with median 6 minutes of acquired PET data, adapting to RG images. Differences in SUVmax, tumor to muscle ratio (TMR), tumor to blood ratio (TBR) and hypoxic volume (HV) between RG and NG images were analyzed. We defined hypoxia as the area with TBR ≥ 1.50. Results: In RG images, SUVmax, TMR and TBR increased in 10 patients comparing to those in NG images. RG images analysis demonstrated significant increase comparing to NG images for SUVmax (RG: Median 1.90, Range 0.72 - 4.89), (NG: 1.71, 0.64 - 4.92), ($p = 0.008$), TMR (RG: 1.58, 0.53 - 3.54) (NG: 1.43, 0.46 - 3.65) ($p = 0.011$), and TBR (RG: 1.39, 0.50 - 3.90) (NG: 1.31, 0.45 - 3.92) ($p = 0.006$). Measurements in RG images showed increase of up to 22.0% in SUVmax, 23.7% in TMR and 22.0% in TBR from NG images. The hypoxia was observed in 3 patients with NG images, and increased to 5 patients with RG images. HV in RG was also significantly larger than that in NG (RG: 9.9 mL, 0.1 - 53.1 mL) (NG: 9.2 mL, 0.0 - 52.5 mL) ($p = 0.022$). HV increased in all 5 patients from NG images to RG images. Conclusions: FMISO-PET with RG demonstrated higher sensitivity of hypoxic evaluation. RG might be useful tool for the exact targeting to hypoxic area in NSCLC for the radiation therapy.

OP145

Predictive value of intratumoral metabolic heterogeneity features for early treatment failure of tyrosine kinase inhibitor in patients with EGFR mutated NSCLC

S. Ha, S. Park, S. Lee, J. Paeng, B. Keam, T. Kim, D. Kim, D. Heo; Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF.

Aim: Intratumoral heterogeneity has been associated to treatment failure and patient prognosis. We hypothesized that intratumoral metabolic heterogenetiy measured by textural analysis on pretreatment [F-18] fluoro-deoxyglucose positron emission tomography/computed tomography has predictive value in targeted therapy in patients with non-small cell lung cancer (NSCLC)Materials and methods: NSCLC cases with activating EGFR mutation treated with tyrosin kinase inhibitor (TKI) were retrospectively reviewed. Eight selected textural features (TFs) were explored for predictive value in test set

(n=161) and applied in validation set (n=21) for survival analysis. Recursive partitioning method was used to find the optimal cutoff value and Harrell's C index was used to calculated predictive value.Results; All the 8 TFs had significantly increased harzard ratio (HR) for progression free survival (PFS) in univariate analysis (e.g. local entropy: HR 6.41, 95% confidential interval [CI] 2.80-14.68). Multivariate analysis with initial stage, performance status (PS), and metabolic volume showed independent predictive value of TFs (HR 4.86, 95% CI 1.97-11.98 by local entropy). TFs had incremental predictive value of early TKI failure compared to stage and PS (C-index 0.596 vs. 0.662, P=0.024, by local entropy).Conclusion: TFs for intratumoral metabolic heterogeneity are significant predictive factors for TKI treatment in EGFR mutant NSCLC patients. These TFs could be used for companion diagnostic markers for identification of a risky population of early EGFR TKI failure. Correlation study to genomic alteration should be needed in future.

OP146

Correlation of metabolic information on PET/CT and tissue expression of HIF-1α and CD68$^+$ macrophages in surgically treated NSCLC

E. Lopci[1,2], F. Grizzi[1], L. Toschi[1], D. Rahal[1], L. Olivari[3], F. Marchesi[1], D. Qehajaj[1], N. Cortese[1], G. Finocchiaro[1], S. Mattioli[2], M. Roncalli[1], S. Fanti[4], A. Santoro[1], A. Chiti[1]; [1]Humanitas Clinical and Research Hospital, Rozzano (Milano), ITALY, [2]Alma Mater Studiorum University, Bologna, ITALY, [3]University of Milan, Milano, ITALY, [4]University Hospital S. Orsola-Malpighi, Bologna, ITALY.

Purpose: It is largely recognized that tumour hypoxia hampers the efficacy of chemo- and radio-therapy, and negatively affects the outcome of different cancers. Herein we investigate the role of FDG-PET parameters in surgical treated Non-Small Cell Lung Cancer (NSCLC), by comparing the imaging findings with the tissue expression of hypoxia inducible factor (HIF-1α) and the amount of CD68$^+$ macrophages. Materials and Methods: A series of 29 patients with up-front resectable NSCLC (stage IA-IIIA; M:F=22:7), who underwent FDG-PET examination prior to surgery, was enrolled consecutively in the study. PET images were visualized on a GE Advanced 4.6 workstation and used to define semi-quantitative and quantitative parameters: SUV_{max}, SUV_{mean}, metabolic tumour volume (MTV) and total lesion glycolysis (TLG=MTV*SUVmean). Surgical histological specimens were analyzed and for each patient two consecutive 2μm-thick sections were treated with antibodies raised against HIF-1α (R&D Systems, Milan, Italy) and CD68 (Dako, Milan, Italy) following a standardized immunohistochemical protocol. The immunoreactivity was semi-quantitatively evaluated and the obtained scores compared with imaging findings. Results: Immunohistochemical staining on NSCLC demonstrated an up-regulated expression of HIF-1α in 17 out of 29 (60%) specimens. The intensity of immunoreactivity was categorized as follows: weak (score 1) in 8 cases, moderate (score 2) in 5 cases, and high (score 3) in 4 cases. When compared to PET data, SUV_{max}, SUV_{mean} and TLG resulted significantly correlated to the intensity of HIF-1α expression ($p<0.05$). More specifically, score 2 demonstrated the highest semi-quantitative and quantitative values compared to score 1, consistent with low hypoxia level, but also to score 3: this latter result appears more likely related to the increased presence of tumour necrosis and expression pattern heterogeneity associated to higher levels of hypoxia. CD68$^+$ macrophages were consistently present in all of the investigated specimens, confirming their functional role in tumour hypoxia. Conclusions: Although our findings need to be extended in a larger series of NSCLCs, the present study shows a direct association between FDG-PET parameters and the tumor expression of HIF-1α . Moreover, macrophages are found as the most representative immune cell population, being present at high densities in all the investigated specimens.

OP147

Correlation between circulating tumor biomarkers and positron-emission tomography in advanced non-small cell lung cancer

G. Ferrarazzo[1], F. Bongioanni[1], C. Genova[2], M. Massollo[3], G. Karalis[4], E. Rijavec[2], F. Biello[2], G. Barletta[2], S. Coco[2], A. Alama[2], A. Truini[2], I. Vanni[2], G. Sambuceti[1], F. Grossi[2], **S. Morbelli**[1]; [1]Nuclear Medicine Unit, IRCCS San Martino - IST, University of Genoa, Genoa, ITALY, [2]Lung Cancer Unit, IRCCS San Martino - IST, Genoa, ITALY, [3]Nuclear Medicine Unit, Galliera Hospital, Genoa, ITALY, [4]PET/CT Alliance Medical, Istituto Salus, Genoa, ITALY.

Background: Circulating tumor cells (CTCs) and plasma circulating-free DNA (cfDNA) are promising candidates as non-invasive prognostic markers in malignant diseases. 18-fluorodeoxyglucose positron emission tomography/computed tomography (18FDG-PET/TC) has a well-recognized diagnostic and prognostic value in non-small cell lung cancer (NSCLC). Very little is known about the mutual relationship between circulating biomarkers (CTCs and cfDNA) and 18FDG-PET/CT indicators in NSCLC. Methods: Peripheral blood samples from 28 patients affected by advanced/metastatic NSCLC were collected before starting first-line chemotherapy. CTCs were isolated by size using a filtration-based device (ScreenCell) and then identified and enumerated; cfDNA was isolated from plasma (QIAamp DNA Blood Mini Kit, Qiagen) and quantified by qPCR method using human

telomerase reverse transcriptase (hTERT). All patients underwent 18FDG-PET/TC (Biograph 16 Siemens) at baseline. Maximum diameter (dmax) of the primary lesion (T), dmax of the greater lymph nodal (N), and metastatic (M) lesions were measured. Similarly, maximum and mean standardized uptake value (SUVmax, SUVmean) and size-incorporated SUVmax (SIMaxSUV) were computed for T, N and M, respectively; SIMaxSUV was calculated with the following formula for T, N, and M: SIMaxSUV= SUVMax*dmax. Presence (B+) and absence (B-) of metabolically active bone lesions (bone mets) were recorded. The association among CTCs, cfDNA and 18FDG-PET/CT-derived parameters was evaluated through multivariate analysis. T-test was performed to evaluate the difference in CTCs and cfDNA in B+ and B- groups, respectively. Results: Twenty-eight patients were evaluated; median age was 66 years (range: 51-80); male/female ratio was 18/10; 15 patients were current smokers, while 11 were former-smokers and 2 were never-smokers. Histo-types were grouped as it follows: adenocarcinoma= 22; squamous cell carcinoma= 5; not otherwise specified NSCLC= 1. Nine patients out of 28 had metabolically active bone lesions. Median CTC count was 7 CTCs/3ml (range: 0-47 CTCs/3ml), while median HTERT copy number was 109.0 (range: 16.7-1405-5). At multivariate analysis, SUVmax of T was the only variable independently associated with cfDNA (p=0.036). No correlations were highlighted between CTCs and all the other PET-derived parameters. A trend towards significance between high HTERT and the presence of metabolically active bone lesions was observed (p=0.058). Conclusions: Our data demonstrate that the expression of cfDNA is correlated with the metabolic activity of the primary tumor lesion. Since SIMaxSUV was not correlated with HTERT, it appears that the expression of cfDNA depends from tumor metabolism rather than its burden. Further analyses on 18FDG-PET/TC-derived metabolic tumor volume are ongoing.

OP148

Density cut off value for metastatic mediastinal and hilar lymph nodes in lung cancer patients

P. Flechsig, P. Frank, D. Rath, C. Kratochwil, H. Kauczor, U. Haberkorn, F. Giesel; University Hospital Heidelberg, Heidelberg, GERMANY.

Purpose:Lung cancer often co-exits with chronic lung diseases such as COPD, and mediastinal lymph nodes may be positive with FDG-PET due to inflammatory disease alone. Nevertheless, FDG-PET is the primary imaging modality used for staging patients with lung cancer, including nodal status. The purpose of this study is to evaluate if density measurements by means of Volumetric CT histogram analysis can improve the characterization of lymph nodes in staging of patients with lung cancer.Materials and Methods:248 lymph nodes of 159 patients aged 41-78 years (87 male, median age 57) diagnosed with lung cancer were investigated. Native FDG-PET/CT (Biograph 6 PET/CT) was performed prior to surgery/biopsy as part of clinical staging. Analysis of lymph nodes was done on the basis of FDG-uptake (SUVmax) and Volumetric CT histogram analysis. These findings were correlated to the gold standard of histopathology.Results:130 positive and 118 negative histological proven lymph nodes were successfully analyzed by Volumetric CT histogram. Histological positive lymph nodes presented a significantly higher median CT HU value ($p < 0.05$, Fig. 1). The incidence of malignancy was 82% above a cut off value of 20HU, the incidence of benign findings was 91% below a cut off value of 20HU. In subgroup analyses, density analyses failed to differentiate between different malignant tumour entities (Adeno CA, Adenosquamous CA, NET, SCLC, other).Conclusion:As an additive value for the preoperative N-staging in lung cancer patients a possible cut off value of 20HU might divide mediastinal lymph nodes of FDG-equivocal patients into affected and not-affected ones. Nevertheless, density analyses cannot differentiate between different tumour entities.

OP149

Comparison of predicted FEV1 and observed FEV1 post lung surgery Using lung Perfusion scintigraphy

V. Rangarajan, N. Purandare, A. Agrawal, S. Shah, S. Nag, P. Ranganathan, C. S. Pramesh; Tata Memorial centre, Mumbai, INDIA.

Aim: To study the correlation between predicted FEV1evaluated by lung perfusion and actual post -operative values of FEV1 in patients undergoing surgery for lung cancer. Materials & Method: This was IRB approved prospective study of patients undergoing lung surgery(lobectomy/pneumonectomy) who were referred for pre-operative prediction of post-operative pulmonary function by lung perfusion scintigraphy using 99mTc MAA. All patients underwent surgery within 2 weeks of the 99m Tc MAA study. Post-operative spirometry study was conducted 4-6 months after surgery. A sample size of 50 was estimated and data collected over 18 months. The estimation of post-operative FEV1 was calculated using actual preoperative FEV1 and percentage perfused lung using a software that divides both lungs into 3 equal zones - anterior and posterior and counting using geometric mean. On the basis of type of planned surgery popFEV1 was calculated as percentage and absolute value. Pearson's correlation coefficient was used to evaluated the relationship between the popFEV1 by lung perfusion scintigraphy and post-operative actual FEV1 measured by spirometry. Agreement

between the 2 methods was analyzed by Bland -Altman method. Results - 50 patients were included in the study. The age range was 32-77 years, males were 39 and 11 were females.50% had upper lobe, 26% had lower lobe, 6% had middle lobe, 12% had main bronchus involvement and 4% others. Histologically 42% were adenocarcinoma, 16% NET, 36% squamous carcinoma and others 6%. The correlation between PPOFEV1 lung perfusion scintigraphy and measured actual post-operative FEV1 by spirometry showed a statistically significant correlation, R=0.847. The correlation coefficient was higher at 0.930 for pneumonectomy patients against 0.792 for lobectomy. The Pearson's correlation coefficient is significant at the 0.01 level (2-tailed). The agreement analysis using Bland-Altman method showed a mean difference between the 2 methods of evaluation of pulmonary function was 0.0558 (mean) with standard deviation 0.284. Conclusion - The current method of quantification using geometric mean and planar method is exceptionally good for predicting lung function after pneumonectomy, however post - lobectomy the planar method is just optimal for prediction. SPECT and CT based segmentation improves the prediction post lobectomy as well. Preoperative FEV1 estimation using lung perfusion is a reasonably good predictor of actual post operative FEV1 in patients undergoing surgery for lung cancer.

OP150

The Relationship between Staging and SUVmax in Non-Small Cell Lung Cancer

H. KAYA[1], **T. Balci**[2], H. KOMEK[3], M. CENGIZ[4]; [1]DicleUniversity Medical Faculty, DIYARBAKIR, TURKEY, [2]Firat University Medical Faculty, ELAZIG, TURKEY, [3]Diyarbakir State Hospital, DIYARBAKIR, TURKEY, [4]Dicle University Medical Faculty, DIYARBAKIR, TURKEY.

Introduction: In this study, we aimed to determine the relationship between the stage of the disease and the maximum standard uptake value (SUVmax), one of the most important quantitative parameters of PET imaging for tumors, in non-small cell lung cancer (NSCLC).Materials and Methods: Seventy three patients with histopathological diagnosis of NSCLC (27 adenocarcinomas, 29 squamous cell lung carcinoma, 17 unclassified subtypes) to whom PET/CT scan was performed between July 2009 to July 2011, were evaluated retrospectively.F-18 fluoro-2-deoxy-D-glucose (FDG) of 370-555 MBq (10-15 mCi) was injected via a peripheral vein of the patients at least 4 hours fasting period and blood glucose levels under the 150 mg/dl and 45-60 minutes following injection PET/CT imaging was performed of the body areas between the vertex and the third upper part of the thigh.In addition to the visual evaluation of the PET/CT images, SUVmax in the tumor tissue and mediastinal lymph nodes was determined. FDG uptake of the lymph nodes, distant metastasis and tumor were assessed by the PET / Ct and they were recorded to make staging according to tumor, node, metastasis (TNM) staging system (Phase I, II, III, IV). The cut-off value for SUVmax was considered as 2.5.The relationship between the NSCLC subtypes and SUVmax were determined by Spearman's correlation test.Results: The patients with an average age of 61.36 ± 9.6 years (32 to 83 years old), 10 women (13.7%) of them, included in the study.Distribution of patients according to the stage was as follows; stage I: 14 patients (19.2%), stage II: 12 patients (16.4%), stage III: 20 patients (27.4%), Stage IV: 27 patients (37%).SUVmax values according to the stage was determined as; Stage I: 11.6 ± 4.6, Stage II: 13.5 ± 6.4, Stage III: 12.6 ± 4.8, Phase IV: 17.5 ± 8.6.In NSCLC subtypes, a significant correlation between SUVmax and the stage was revealed ($r = 0.319$, $p = 0.006$).Conclusion: Due to positive relationship between the increase in SUVmax and tumor stage, we believe that it could help clinicians in order to make a prediction about the patient's prognosis.

Size doesn't matter: predictive value of new quantitative analysis for differential diagnosis of primary hyperparathyroidism lesions vs. thyroid nodular disease in parathyroid scintigraphy

A. V. Koljevic Markovic[1,2], M. Jankovic, G. Pupić[1], R. Džodić[1]; [1]National Cancer Research Center Serbia, Belgrade, SERBIA, [2]Faculty of Electrical Engineering, University of Belgrade, Belgrade, SERBIA.

Aim: The problem of segmentation and recognition of parathyroid lesions in the presence of concomitant thyroid nodular disease is present in conventional SPECT/CT investigations as well as in gamma camera imaging. Aiming to improve specificity of parathyroid scintigraphy in concomitant thyroid nodular disease, we developed a new processing method in ROI time/activity data analysis. MM: Total of 53 patients, median age of 57(19-80) years, with clinical diagnosis hyperparathyroidism (PHPT) and ultrasound positive report of nodular or multinodular goiter, underwent preoperative, dual- tracer: 99m Tc-pertecnetat and 99mTc-MIBI, double- phase scintigraphy by EANM guidelines (2009). Specially designed software we developed examined ROI time/activity changes in the form of grid with different, optional sizes, up to maximal resolution (1, 5mm). We correlated our findings with PTH levels, histology

results and conventional scintigraphic findings: subtraction and visual interpretation of planar images of neck and mediastinum in oblique sections, according to ultrasound PTA localization and delayed scans in one hour interval. Results: Parathormone (PTH) was increased in the group: median 120,2 pg/ml (range 70- 658pg/ml).Following histopathology: a) thyroid - benign: adenoma folliculare, colloides and cystica: 45(83%)pts ; malignancy: 8 (10%)pts- papillary 7 pts and one for medullary; b) parathyroid - autonomy (PTA) 53(70,2%): solitary: 44 patients, hyperplasia: 8 pts- 7/8 patients with two lesion and 1/7 had all four lesions and one PT carcinoma;.c.) median PTA volume was 760(55-6125)mm^3. Standard findings (subtraction, oblique planar scans and delayed phase) in total of 63 lesion (in 53 pts) had 10 FN (mostly in hypeplasia PTA), and PPV was 81%. Using specially designed software, thyroid TACs represented, as expected, exponentially declining curves but parathyroid lesions had typical uptake pattern in the form of late phase peak, independent to PTA volume and/or PTH levels. The thyroid gland washout was up to 28% in normal, adenoma or thyroid carcinoma tissue. A new processing method for a PTA had PPV 97%. Conclusion: Application of new imaging data quantification, we developed, was effective in small parathyroid lesions concomitant to thyroid nodular disease, complementary used with standard protocols. This novelty could be implemented in various nuclear medicine hybrid imaging investigations, following pathological metabolism, in ROI sizes up to maximal resolution.

OP152

A prospective comparative study of parathyroid dual-phase scintigraphy, dual-isotope subtraction scintigraphy, 4D CT, and ultrasonography in primary hyperparathyroidism

M. Krakauer[1], B. Wieslander[1], P. S. Myschetzky[1], A. Lundstrøm[1], T. Backer[1], C. H. Sørensen[2], W. Trolle[2], B. Nygaard[3], F. N. Bennedbæk[3]; [1]Gentofte Hospital, Helleup, DENMARK, [2]Rigshospitalet, Copenhagen, DENMARK, [3]Herlev Hospital, Herlev, DENMARK.

Purpose: Preoperative localization of the diseased parathyroid gland(s) in primary hyperparathyroidism (PHP) allows for minimally invasive surgery. This study was designed to establish the optimal first-line preoperative imaging modality. Methods: 91 patients were studied consecutively in a prospective head-to-head comparison of dual isotope (Tc-99m Sestamibi vs. I-123) subtraction parathyroid scintigraphy (PS), dual-phase PS, 4D CT, and ultrasonography (US). Surgery, histological confirmation, and postoperative normalization of Ca^{++} and PTH was the reference standard. Results: Ninety-seven hyperfunctioning parathyroid glands (HPG) were identified by the reference standard. Sensitivity and specificity for subtraction PS, dual-phase PS, 4D CT, and US was 93%, 65%, 58%, 57% and 99%, 99.6%, 86%, 95%, respectively. Inter-rater agreement was excellent for subtraction PS (κ=0.96) while only fair for 4D CT (κ=0.34). Pinhole imaging and subtraction of late images (the latter especially in case of a nodular thyroid gland) increased the sensitivity of subtraction PS. SPECT/low-dose CT did not increase sensitivity but aided in the exact localization of the HPGs. Of 7 negative subtraction PS studies 4D CT and US was able to locate 3 and 1 additional HPGs, respectively. Conclusions: Dual isotope pinhole subtraction PS has higher diagnostic accuracy compared to dual-phase PS, 4D CT, and US as a first-line imaging study in PHP. In case of a negative scintigraphy or suspicion of multiglandular disease 4D CT and/or US is recommended as a second-line modality. However, diagnostic algorithms should be adapted in accordance with local availability and expertise.

OP153

Comparison of 99mTc-sestamibi/123I subtraction SPECT/CT and combined 99mTc-sestamibi/123I sub-traction SPECT/CT with planar pinhole image in hyperparathyroidism

V. Tunninen[1], P. Varjo[1], M. Seppänen[2]; [1]Satakunta Central Hospital, PORI, FINLAND, [2]Turku University Hospital, Turku, FINLAND.

Introduction. ^{99m}Tc-sestamibi/^{123}I subtraction SPECT/CT is a valuable tool for localization of parathyroid adenomas. The aim of this study was to evaluate whether the review of additional planar pinhole image improves the outcome of ^{123}I/^{99m}Tc -sestamibi subtraction SPECT/CT in parathyroid scintigraphy. Subjects and Methods: Parathyroid scintigraphy with ^{99m}Tc (750MBq) and ^{123}I (20MBq) was performed for 59 patients with hyperparathyroidism (55 pHPT, 4 sHPT). Two simultaneous ^{99m}Tc /^{123}I acquisitions were performed (SPECT/CT and anterior planar pinhole imaging). Two anonymized image sets were generated to compare SPECT/CT and combined SPECT/CT+Pinhole planar images (^{99m}Tc-sestamibi,^{123}I, and subtraction images). Each quadrant in relation to the thyroid gland (and other, referring to ectopic localization) was classified as negative or positive with the confirmation of histologic analysis as the reference standard. A McNemar test was performed to compare the sensitivities and specificities between the image sets. Results. There were 68 adenomas confirmed by histology in 59 patients. Fifty-two patients had solitary adenomas, six patients had double adenoma, and one patient had four hyperplastic glands. Sixty-two and sixty-six adenomas were correctly visualized by SPECT/CT (six false positive) and SPECT/CT+Pinhole (four false positive), respectively. The sensitivity and specificity were

slightly higher with SPECT/CT+Pinhole than with SPECT/CT (97,06% vs. 91,18% and 98,24% vs. 97,36%, respectively. p = 0,7237). False-positive rate was 8,82% with SPECT/CT, and decreased to 5,71% with SPECT/CT+Pinhole.Conclusion. This study indicates that the use of additional pinhole image with ^{99m}Tc-sestamibi/^{123}I subtraction SPECT/CT increases both sensitivity and specificity of parathyroid scintigraphy. Although the difference was not statistically significant, the use of additional pinhole imaging is useful especially in cases where SPECT/CT remains negative. The use of additional planar pinhole image with ^{99m}Tc-sestamibi/^{123}I subtraction SPECT/CT is thus recommended in selected cases.

OP154

Value of 18F-Choline PET-CT in the assessment of primary hyperparathyroidism comparing with 99mTC-Sestamibi SPECT-CT

M. Beheshti[1], **L. Imamovic**[1], G. Spaun[2], M. Steinmair[1], K. Emmanuel[2], V. Alibegovic[3], C. Pirich[4], W. Langsteger[1]; [1]PET-CT Center Linz, St. Vincent's Hospital, Linz, AUSTRIA, [2]Department of Surgery, St. Vincent's Hospital, Linz, AUSTRIA, [3]Department of Clinical Pathology, St. Vincent's Hospital, Linz, AUSTRIA, [4]Nuclear Medicine & Endocrinology, Parcelsus Medical University, Salzburg, AUSTRIA.

Aim: In this prospective study we compared the accuracy of 18F-Choline (FCH) PET-CT with 99mTC-Sestamibi SPECT-CT for preoperative detection of parathyroid adenoma in patients with primary hyperparathyroidism. METHODS: Both 99mTC-Sestamibi SPECT-CT and FCH PET-CT were performed in 25 consecutive patients with biochemical evidence of primary hyperparathyroidism. At least one abnormal 99mTc-Sestamibi and FCH focus corresponding to a parathyroid gland or ectopic parathyroid tissue in each imaging modality was considered as positive finding. Twenty patients with positive findings in at least one imaging modality underwent surgical exploration and the results of imaging modalities were verified with histopathologic findings as the standard of truth. RESULTS: All patients showed biochemical evidence of primary hyperparathyroidism with a mean serum calcium level of 2.7 ± 0.4 mmol/l and parathormone (PTH) level of 178.5 ± 165.8 pg/ml. Intraoperative PTH monitoring showed significant drop in PTH level in all patients. In patient-based analysis, FCH PET-CT was able to detect parathyroid adenoma in 84% of patients (21/25) while 99mTC-Sestamibi SPECT-CT was positive in 52% of patients (13/25). The mean serum calcium and PTH levels of patients with negative imaging modalities were 2.66 ± 0.05 mmol/l and 123.05 ± 18.0 pg/ml. In a lesion-based analysis in 20 patients who underwent surgical exploration, the detection rate of FCH PET-CT was 87% (21/24) comparing with 50% (12/24) detected by 99mTC-Sestamibi SPECT-CT. CONCLUSION: In this prospective study, FCH PET-CT showed promising results to be a potential functional imaging modality - clearly superior to 99mTC-Sestamibi SPECT-CT - in the detection and localization of parathyroid adenoma in patients with primary hyperparathyroidism.

OP155

Tc-99m MIBI-scintigraphy for malignancy risk assessment of hypofunctionning thyroid nodules

K. Rösel, C. Schneider, C. Kobe, M. Dietlein, A. Drzezga, **M. C. Schmidt**; University Hospital of Cologne, Department of Nuclear Medicine, GERMANY.

Aim: In Germany with its borderline iodine supply patients with hypofunctionning thyroid nodules (HTN) as assessed by pertechnetate scintigraphy have a malignancy risk of about 1.7 - 3 %. Fine needle aspiration cytology is used for futher evaluation being inconclusive in about 20%. Tc-99m-MIBI scintigraphy can be used for malignancy risk assessement of HTN. We wanted to test its clinical usefulness.Methods: Between 2007 and 2010 108 patients with one HTN were retrospectively identified from our institutional database who had undergone Tc-99m-MIBI-scintigraphy and subsequent surgery. Histopathology served as golden standard. Tc-99m-MIBI images were grades as following: Match = HTN and MIBI with a concordant lower uptake as the surrounding thyroid tissue; Isointense Uptake = MIBI uptake in the HTN equal to surrounding thyroid tissue; Mismatch = MIBI uptake higher than surrounding thyroid tissue. Results: 98 patients had a benign and 10 a malignant histology. Patients with benign nodules had 34 Match, 11 isointense and 51 Mismatch findings. Patients with malignant nodules had 8 Mismatch and 2 isointense findings the latter being explained by papillary microcarcinomas. The negative predictive value of Tc-99m-MIBI scintigraphy was 96% and the positive predictive value 14%. Fine needle aspiration biopsy being performed in 77 patients missed 6 malignant nodules. Conclusions: Tc-99m-MIBI scintigraphy can serve as an additional technique for malignancy risk assessment of hypofunctionning thyroid nodules. Though the majority of Mismatch findigs represent benign thyroid nodules the likelihood of malignancy increases in this group. A negative Tc-99m-MIBI scintigraphy has a high likelihood of a benign finding justifying a conservative

management. Though small in number, Tc-99m-MIBI may miss papillary microcarcinomas.

OP156

Role of real time ultrasound elastography in diagnosing hyper functional thyroid nodules and predicting treatment response

V. Stebner[1], M. Ruhlmann[1], R. Görges[1], J. Farahati[1], D. Simon[2], A. Bockisch[1], S. Rosenbaum-Krumme[1], J. Nagarajah[3]; [1]Department of Nuclear Medicine, Medical Faculty, University Duisburg-Essen, Essen, GERMANY, [2]Department of General and Visceral Surgery, Bethesda Hospital, Duisburg, GERMANY, [3]Department of Radiology, Memorial Sloan Kettering Cancer Center, New York, NY, UNITED STATES.

Background/AimUltrasound based real-time elastography (USE) is increasingly studied in clinical setting primarily for detection of suspicious thyroid nodules with controversy results. However, the role of USE for diagnosis of scintigraphically hyper functional thyroid nodules is still unclear. In this study we investigated the detection capability of USE for benign thyroid nodules and analyzed additionally, if USE is able to predict radio-iodine treatment (RIT) response in those patients.The first part of the study included 134 hyper functional thyroid nodules of 101 consecutive patients. The following attributes of the nodules were analyzed: stiffness with the USE using scores of Rago (3 item score) or Asteria (5 item score) and ultrasound criteria using TIRADS. The second part of the study included 73 hyper functional thyroid nodules (51 unifocal, 7 bifocal, 15 multifocal) of 73 consecutive patients prior to RIT. The following attributes of the nodules were analyzed before RIT: stiffness with the USE using scores of Rago (1 = soft, 2 = medium, 3 = hard), classical ultrasound criteria like echogenicity and perfusion, thyroid scintigraphy and TSH level in blood. Approximately four months after RIT the therapy response was evaluated by thyroid scintigraphy and TSH level in blood. Therapy response was defined as normalized TSH level and thyroid scintigraphy without hyper functional nodules.94 of the exmined thyroid nodules (70%) were rated as hard (suspicious for malignancy) and 41 nodules (30%) as soft (not suspicious) with a specificity of 30%. The scoring systems of Rago and Asteria showed no significant difference. Applying the TIRADS criteria 44 nodules (33%) had a higher risk for malignancy (33 nodules TIRADS 4a, 11 nodules TIRADS 4b). Combining USE and TIRADS 32 nodules (24%) were categorized as suspicious (intersection of hard nodules that are categorized as TIRADS 4a or 4b).RIT was successful in 66 nodules (responder) and not successful in 7 nodules (non-responder). In the group of responders 21 nodules were rated as “soft”, 12 nodules as “medium” and 33 nodules as “hard”. Regarding the non-responder 4 nodules were rated soft and 3 nodules hard. There was no statistic significant correlation between USE score and therapy response.ConclusionUSE cannot reliably identify scintigraphically hyperfunctional thyroid nodules as benign nodules. Its accuracy in the assessment of at least “hot” thyroid nodules is to be questioned. USE cannot predict therapy (non-) response of RIT of hyper functional thyroid nodules and has therefore no influence on therapy planning.

OP157

Cancer Risk After Medical Exposure to 131I in Benign Thyroid Diseases

I. CILLERO ETXEBESTE, A. MENDIOLA, P. SANTESTEBAN, M. MITXELENA, I. ARIAS-CAMISON, G. RIOS, F. RODRIGUEZ; FUNDACIÓN ONKOLOGIKOA, SAN SEBASTIAN, SPAIN.

OBJECTIVE: The objective of this study was to evaluate the incidence of cancer in patients treated with ^{131}I for benign thyroid disease. MATERIAL AND METHODS: This is a retrospective study in which a total of 1511 patients , residents in Guipúzcoa (Spain), were included from 1995 to 2011. All of them had received a radioiodine treatment (RAI) for Grave’s disease, autonomously functioning nodules (AFN), multinodular goiter (MNG) or treatment refractory hyperthyroidism. The administered ^{131}I dose was calculated on the basis of the thyroid’s volume, 24h uptake of ^{131}I and clinical examination. The dose range was 185-740 MBq. The observed variables were: reason for ^{131}I treatment, administered activity of ^{131}I, thyroid absorbed dose, other organ groups that concentrate ^{131}I, time since exposure and pathological anatomy examination. We reviewed the most sensitive organs for radiation-induced oncogenesis including salivary glands, breast, kidney, bladder, pancreas, stomach and thyroid. Lymphoma and leukemia’s incidence in these patients was also studied. Incident cancer cases were identified from Guipúzcoa’s Cancer Registry. Standardized incidence rate (SIR) was estimated as an approach to cancer risk. RESULTS: This study included 1217 women and 294 men. The median age was 58.37. The follow-up period of these patients ranged from 1 to 16 years. Thyroid cancer was diagnosed in 10 patients during the follow-up period. .All patients who developed a thyroid cancer were men. Among these 10 patients, the average ^{131}I was 573.5Mbq. Five of these patients were treated for AFN whereas the other five patients suffered from MNG. None of these patients were treated for Grave’s disease. Pathological examination revealed a prevalence of papillary tumour (6/10) two patients presented follicular tumour, one present medullary thyroid carcinoma and one leiomyosarcoma. Three patients died of thyroid cancer. Among these 3 tumours one was a papillary tumour, one was leiomyosarcoma and one

was medullary carcinoma. SIR was 4.3 (CI: 0.86-0.71) which is similar to Gipúuzcoa's general population. CONCLUSION: The incidence of thyroid cancer in these series was not significantly different from its incidence in the general population. There is no demonstrable increase of risk overall after ^{131}I administration in our study.

OP158

Contribution of SPECT/CT in extrathyroid radioiodine uptake in patients with differenciated thyroid cancer.

J. Villanueva Curto, A. Sainz-Esteban, A. Cobo Rodríguez, C. Gamazo Laherrán, M. Ruíz Gómez, M. Gónzalez Selma, M. Alonso Rodríguez, R. Olmos García; HOSPITAL CLÍNICO UNIVERSITARIO DE VALLADOLID, Valladolid, SPAIN.

Aim:To asses the contribution of SPECT/CT performed after treatment with 131I in patients with differentiated thyroid cancer (DTC) in the localization and characterization of extrathyroid uptakes detected in the whole body scintigraphy (WBS).Methods:We include 40 patients (31 women, mean age: 57±18 years) with DTC (35 papillary, 2 follicular and 3 indiferentiated). After an hipoiodine diet, a WBS and a SPECT/CT were performed 6-9 days after the administration of a therapeutic dose of 131I (mean dose: 4.2 ± 0.8 GBq) and 4 weeks after withdrawal of hormonal replacement treatment (21) or stimulation with recombinant TSH (19). Scintigraphy findings were correlated with radiology, histology or follow-up.Results:In 11 patients, WBS and SPECT/CT did not show any extrathyroidal uptake. In the remaining 29 patients, 44 foci were detected. Three foci were only detected in SPECT/CT, 2 of them were metastases in cervical adenopathies and one a bronchiectasis. Of the 41 foci detected in both techniques, 12 were metastases (9 cervical adenopathies and 3 distant metastases), and 29 were false positives. SPECT/CT improved the localization of all of them, dismissing 26 false positives in salivary glands (3), bowel (7), kidney (1), thymus (5), breast (1), bronchiectasis (4), and contamination (5). In 3 patients, in spite of the improvement of localization, SPECT/CT did not correctly characterize three foci that were at final diagnosis a bronchiectasis, a renal and an ovaric cysts.Conclusions:SPECT/CT improved the localization and characterization of extra thyroid uptakes detected in WBS, dismissing false positives. In a small percentage of patients, new focus were detected in SPECT/CT, with no changes in the staging of patients.

18F-FDG PET/CT: Is SUV reliable to evaluate the adrenal glands normal metabolic behavior?

I. Rodrigues, A. Martins, J. Pereira, R. Domingos, S. Carmona, L. Oliveira; Joaquim Chaves Saúde – Nuclear Medicine Department, Lisbon, PORTUGAL.

Aim: To compare normal adrenal glands (AG) SUVmax obtained in two different time points, using two reconstruction methods, in order to evaluate SUV reliability to evaluate AG normal metabolic pattern.Materials and methods: This retrospective study included 56 AG of 28 patients [13M/15F; mean age: 61,4 ± 12,9 years] with glycemic values below 120mg/mL and without adrenal disease (excluded by clinical history, recent image and laboratory tests). The technical procedure consisted of the administration of 18F-FDG followed by a rest period and hydration. Two PET/CT studies were performed [Biograph 6 TrueView PET/CT, Siemens]: a whole body study from the base of the skull to the mid-thigh (WB) (Δinjection-acquisition= 94,4 ± 15,9 minutes) and a delayed abdominal image (DAI) (Δinjection-acquisition= 180,6 ± 24,1 minutes). The CT study was acquired with low dose protocol for attenuation correction and anatomical localization. The processing included the visual analysis of the tomographic studies and the calculation of SUVmax in AG in the WB and in DAI by two different iterative reconstruction methods: 1) SUVmax_2D [8 subsets, 4 iterations, matriz 168x168] SUVmax_3D [21 subsets, 3 iterations, matriz 336x336]. Statistical analysis was performed using paired t-Student test.Results: In initial images, the mean SUVmax_2D (2,00 ± 0,40) are not statistically different (p=0,168). In DAI SUVmax_3D (2,20 ± 0,48) is higher than SUVmax_2D (1, 96 ± 0,52) (p=0,001). Comparing the mean SUVmax_2D of AG in initial and delayed images, the differences found with both reconstruction methods were not statistically different, although both reconstruction methods showed a different tendency: there is a slight mean SUVmax decrease (-2,48 %) for SUVmax_2D and a slight SUVmax increase (5,26 %) for SUVmax_3D.Conclusion: Small differences in reconstruction methods can happen when hardware and/or software is upgraded and this can significantly change the normal AG SUV calculation. This change can be non-homogeneous as verified in this work - we have documented no significant AG SUV change in the initial WB images and a significant SUV change on the DAI, using two reconstruction methods. This aspect conducted to an apparent different metabolic behavior of normal AG during time - although the differences were not statistically significant, a slight increase or slight decrease in AG SUV was documented during time as different reconstruction methods were used.

Partial Volume Correction of Amyvid and FDG PET data using the discrete iterative Yang technique

J. C. Dickson[1], K. Erlandsson[2], M. Lehmann[2], M. Modat[2], N. Burgos[2], A. Groves[2], J. Schott[2]; [1]University College London Hospital NHS Foundation Trust, London, UNITED KINGDOM, [2]University College London, London, UNITED KINGDOM.

Introduction: Partial volume effects can severely compromise both visual and quantitative PET, particularly in the populations referred for dementia PET imaging. Atrophy and cortical thinning can lead to apparent reductions in tracer uptake that are purely an effect of anatomical features, which compromises the ability of the PET study to accurately map underlying physiological processes. To overcome these issues, partial volume correction (PVC) techniques can be applied. In this study we introduce the "discrete iterative Yang" (diY) technique, and look at the improvement in tracer uptake in a cohort of Amyloid and FDG PET studies. Methods: A mix of twenty-two patients and age-matched controls were involved in this study. All subjects had Amyvid PET, FDG PET, and a recent T1 weighted MR study. T1 data were co-registered to FDG PET and 18F-Amyvid data before being segmented and parcellated into volumes using the Niftyseg algorithm [1]. PET data were then up-sampled to the MR voxel size before PVC was applied using the diY technique. In essence the technique involves the PET image being represented as a piecewise constant image, which is convolved with the system point spread function. The ratio of the original and convolved images is used as correction factors that are applied to the PET image. The regional mean values are estimated iteratively. After a few iterations of this process, the PET image can be considered to be partial volume corrected. Once the correction had been applied, the visual and quantitative changes to the PET distributions were assessed pre and post correction. Results: Of the 22 subjects, 13 had a scan negative for amyloid deposits. After PVC, global grey-matter SUVr in these subjects decreased by an average of 12.2% (95%CI: 8.7-15.7) due to a reduction of spill-in from non-specific white matter uptake. In Amyloid positive patients, SUVr increased by 26.7% (95%CI: 22.17-31.26%) by reducing spill-out from cortical grey matter. Similarly in control FDG studies SUVr in cortical grey matter increased by 26.3% (95%CI: 25.22-27.41) after the application of the PVC. Visually there was better contrast between grey and white matter areas on Amyloid PET, and FDG PET with abnormalities better differentiated with diY PVC applied. Conclusions: Partial volume correction using diY improves quantitative accuracy, and offers better differentiation between normal and abnormal studies.

Prognostic and predictive values of initial 18FDG PET features using random forest classifier: Application to patients after chemo-radiotherapy for oesophageal cancer

P. Desbordes[1,2], R. Modzelewski[3,1], S. Vauclin[2], P. Vera[3,1], I. Gardin[3,1]; [1]QuantIF LITIS - EA4108, University of Rouen, Rouen, FRANCE, [2]Dosisoft, Cachan, FRANCE, [3]Henri Becquerel Center, Rouen, FRANCE.

Aim: Many features can be extracted from 18FDG PET images to describe cancer. We propose a machine learning technique based on a Random Forest (RF) classifier to select features having a prognostic or predictive value among a large amount of different characteristics.Materials and methods: 65 features are extracted from medical records (age, stage ⋯) and PET images: classical features (SUV, Metabolically Tumor Volume (MTV) ⋯), 1st order features (skewness, entropy ⋯) and texture parameters from texture matrices: Gray Level Cooccurrence Matrix (GLCM), Gray Level Zone Length Matrix (GLZLM) and Gray Level Difference Matrix (GLDM). Patient classification is performed using RF algorithm with 2000 decision trees, firstly without any Feature Selection (FS), and secondly with a FS. The selection is performed in 2 steps. First, a correlation analysis is done using the Spearman method to keep uncorrelated features. They are compared two by two and are considered as correlated if the Spearman coefficient (sp) verified $|sp| \geq 0.8$ and $p < 0.05$. Next, the RF algorithm is applied on the remaining features to find the most relevant features using the importance index. The RF classifier has been applied to a database of 66 patients with an oesophageal cancer treated by radio-chemotherapy (CRT). The classification accuracy has been evaluated using the Out-Of-Bag (OOB) error.Results: When the RF classifier is applied to the 65 initial features, OOB error reaches 33.3% and 25.8% for prognostic and predictive studies respectively. The FS strategy improves the classification accuracy, to reach an OOB error of 22.7% and 22.7% respectively. The Spearman analysis revealed that none of the clinical data are correlated with PET characteristics, neither for correlation (GLCM), Cluster Shade (CS, GLCM) Busyness (GLDM) and Zone Percentage (ZP, GLZLM). Twelve groups of correlated features can be created leading to 31/65 features selected. The best 3 prognostic features are MTV, correlation (GLCM) and the Nutritional Risk Index (NRI), whereas the best 3 predictive features are MTV, ZP and correlation (GLCM).Conclusion: ML technique, such as random forest classifier, is an interesting tool to find the

most relevant among a large amount of features, to classify patients. A FS is mandatory to improve the classification accuracy. In case of oesophageal cancer, MTV and texture parameters appear as relevant feature and improve predictions.

OP162

Biomathematical modeling approach to predict clinical SUVR in amyloid PET imaging towards efficient radioligand discovery and development

Y. Arakawa[1], M. Shidahara[1], Y. Nai[2], S. Furumoto[2], C. Seki[3], N. Okamura[1], M. Tashiro[2], M. Tashiro[2], Y. Kudo[1], K. Yanai[1], K. Gonda[1], H. Watabe[2]; [1]Tohoku University School of Medicine, Sendai, JAPAN, [2]CYRIC, Tohoku University, Sendai, JAPAN, [3]National Institute of Radiological Sciences, Chiba, JAPAN.

Aim: Purpose of the study is to develop a new methodology to predict clinical SUVR of amyloid PET radioligands by extending biomathematical modeling, which was previously proposed by Guo et al. [1]. Methods: 6 amyloid radioligands, [11C]PIB, [11C]BF-227, [11C]AZD2184, [18F]FACT, [18F]Flobetapir and [18F]AZD4694 were explored in this study. For each tracers, time-activity curves (TACs) were generated using one-tissue compartment model with arterial plasma input function and calculated kinetic parameters (K1, k2 and BPND). By biomathematical modeling simulation, K1, k2 and BPND values were derived using lipophilicity (logP), apparent volume (Vx), free fraction in plasma (fP), free fraction in tissue (fND), dissociation constant (KD) and density of Amyloid β (Bavail) [1]. Lipophilicity was using ClogP (chemoffice ver. 2012, Hulinks Inc.), moriguchi logP, MlogP (dproperties, Affinity Science corp.). Vx was also computed using dproperties. Both fP and fND were calculated by relational expressions among logP, fND and fP. Regression lines of logP vs. fND and fND vs. fP. were derived from three publications, Guo et al. [1], Summerfield et al. [2] and Wan et al.[3]. KD was obteined from publications. Bavail was fixed at 3nM for healthy control (HC) and 50nM for severe Alzheimer Disease (AD) patient. Predicted SUVRs of HC and AD were then obtained by dividing the summed TACs of the target region over that of the reference region. The predicted SUVRs of HC and AD for each tracer were then compared with previously reported in vivo SUVRs of HC and AD groups respectively. The correlations between predicted and reported SUVRs were compared for 6 combinations of logP and regression line (ClogP-Guo, ClogP-Summerfield, ClogP-Wan, MlogP-Guo, MlogP-summerfield and MlogP-Wan). Results: Good correlations between predicted SUVR(y) and in vivo SUVR(x) were observed in the case of MlogP-Summerfield ($y = 1.05 x + 0.04$, $r2 = 0.70$) and MlogP-Wan ($y = 2.67 x - 1.42$, $r2 = 0.70$). On the other hand, poor correlation was observed in case of ClogP-Guo ($y=0.59x+0.36$, $r2=0.38$). Conclusion:Proposed methodologies (MlogP-Summerfield and MlogP-Wan) were able to predict SUVR with good correlation against in vivo SUVRs for 6 amyloid tracers, showing potential to be applied to other amyloid radioligands. Reference: [1] J Nucl Med. 2009, 50(10):1715-23. [2] J Pharmacol Exp Ther, 2006; 316:1282-90 [3] J. Med. Chem. 2007, 50:4606-15

OP163

Correlation of SUV and tumor to blood standard uptake ratio (SUR) with the metabolic uptake rate derived from quantitative dual time point measurements.

F. Hofheinz[1], J. van den Hoff[1], A. Lougovski[1], K. Ego[2], H. Amthauer[2], I. Apostolova[2]; [1]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, GERMANY, [2]Clinic of Radiology and Nuclear Medicine, University Hospital, Magdeburg, GERMANY.

Aim: Determination of tumor SUV is widely used for quantitative assessment of tumor metabolism in FDG-PET. However, the SUV approach has several well known limitations compromising its ability to act as a surrogate parameter of glucose consumption. Recently, we have shown that SUR overcomes most of these limitations as long as FDG kinetics in the target structure can be considered irreversible [1,2]. Excellent linear correlation of SUR and Km from Patlak analysis was found using dynamic imaging of liver metastases. However, due to the perfectly standardized uptake period used for SUR determination and the comparatively short uptake period these results are not directly applicable to clinical whole body examinations, in which the uptake periods often vary considerably. Therefore, the aim of this work was to investigate the correlation of SUR and Km in clinical whole body scans, where Km was approximated by Ks derived from dual time point (DTP) measurements [3]. Methods: DTP FDG-PET/CT was performed in 76 consecutive patients with histologically proven NSCLC. In the PET images the primary tumor was delineated with an adaptive threshold method. For determination of the blood SUV the aorta was delineated manually in the attenuation CT. The aorta ROI was transferred to the PET image. Blood SUV was computed as the mean value of the aorta ROI. SUR values were computed as ratio of tumor SUV and blood SUV. SUR values were scan-time-corrected to 60 min p.i. as described in [2]. Metabolic uptake rate Ks was computed similar to the procedure in [3]. The correlation of SUV and SUR with Ks was investigated. Results: There was highly significant correlation of SUR and Ks (R^2=0.9). However, the correlation coefficient appeared somewhat lower than previous results obtained from dynamic imaging and standardized uptake times (R^2=0.96 [1]). As expected, SUV showed

markedly lower correlation with Ks than SUR (R^2=0.76). Conclusion: Our results show that in clinical whole body PET the correlation of uptake values with the metabolic trapping rate can be improved notably by blood normalization and scan-time-correction. Furthermore, the high correlation of SUR with Ks indicates that for histologically unambigous tumor lesions DTP do not provide added value in comparison to the SUR approach. Introduction: 99mTc Trodat Brain SPECT is a powerful tool in diagnosis and evaluation of patients with Parkinsonism. However the unavailability of finite resolution and lack of anatomic details makes the interpretation of scans difficult. With the advent of the Fanbeam ultra high resolution collimator (FBUHR), the resolution and sensitivity has increased multifold. Aim: 1. To prove if use of Fanbeam Collimator improves inter-observer agreement within Nuclear Medicine Physicians in regards to interpretation of ^{99m}Tc-TRODAT scans. 2. To compare image quality of FBUHR and Low Energy High Resolution (LEHR) collimator in ^{99m}Tc-TRODAT imaging. Materials and Methods:-^{99m}Tc Trodat scans acquired over a period from January 2014 to April 2015 were included in the study. • 40 scans - 20 from each FanBeam and LEHR were made anonymous, randomised and were given to three nuclear medicine physicians A, B, C, who interpreted them individually as normal and abnormal, the scan quality was interpreted as good and average or poor.• The data was analysed between 3 groups, Group I included A and B, II included B and C, III included A and C. Using Kappa(k) analysis in terms of agreement, <0 suggesting that less than chance agreement, 0.01-0.20slight, 0.21-0.40fair, 0.41-0.60moderate, 0.61-0.80substantial, and 0.81-0.99 almost perfect agreement, 1 is perfect agreement and 0 is exactly what would be expected by chance. Result: Our data indicate that the imaging outcome expressed by the inter-observer agreements and quality of scans has an excellent test reproducibility and correlates with imaging quality and disease severity. In overall evaluation, we found Moderate Agreement in all 3 groups I, II, III with kappa 0.46, 0.525, 0.421 respectively for scan quality and Moderate agreement in group I and III, and Substantial Agreement in the group II for diagnosis of Parkinsonism. Individually, the FBUHR shows kappa value of 0.48, 0.49, 0.56 and LEHR shows -0.041, 0.062, -0.086 in groups I, II, III respectively for Scan Quality which shows moderate agreement in all 3 IOA groups for FBUHR, and less than chance agreement or slight agreement for LEHR Collimator. These findings suggest that ^{99m}Tc-TRODAT BRAIN SPECT imaging using FBUHR is useful and feasible for imaging Parkinsonism with more accuracy than LEHR. Conclusion: The image quality was consistently rated better with the use of FBUHR as compared to the LEHR collimator. This translated in an improved interobserver agreement across scans with the use of FBUHR, resulting in better scan interpretation.

Standardized uptake values of 99mTc-MDP SPECT bone scans - a novel method for absolute SPECT/CT quantification

W. He, W. Zhai, W. Yu; Huadong Hospital, Shanghai, CHINA.

Objectives : To investigate the variation of SUV values in 99mTc-MDP bone scans using SUV SPECT hybrid reconstruction based quantitative methods. Methods: 535 patients (mean age 63.07) without bone metastasis which has been diagnosed by CT and MRI were enrolled in this study ,and they were divided into four groups : 100 cervical vertebra cases , 161 thoracic vertebra cases, 172 lumbar vertebra cases and 102 pelvis cases. To generate SUV-calibrated images, the raw SPECT data was reconstructed using the software 'SUV-SPECT' (HERMES MEDICAL SOLUTIONS). Corrections were applied for CT attenuation, Monte Carlo-modeled scatter correction, resolution recovery, scaling for injected dose and radioactive decay. The units of counts-per-voxel were scaled to activity per unit volume (Bq/cc) based on previously performed phantom calibration work to allow for SUV measurements. The reconstructed images were analyzed using a constrained threshold-based volume of interest approach to automatically calculate the uptake in the bony structures. SUVmax by body weight was recorded in the derived volume. All the values were measured twice to verify consistency.95% medical reference range SUV was generated .Results : The mean SUVmax of cervical vertebra group was 9.78±3.07 (ranging from 5.00 to 17.27), thoracic vertebra8.81 ±2.17(ranging from 5.11 to 12.82),lumbar vertebra 9.64 ±2.48 (ranging from 5.81 to 15.58)and pelvis(ranging from 5.72 to 16.99). The repeated results were consistent.Conclusions : This method is accurate, easy-to-use and robust, providing absolute quantification in SPECT/CT,

which promises to be widely used in primary diagnosis and evaluation of therapy response.

Development of Motion Correction Methods for Cardiac PET Imaging

T. Noponen[1,2], R. Klén[1,3], T. Kokki[1,2], J. Teuho[1], K. Thielemans[4], J. Koikkalainen[5], E. Hoppela[1], H. Sipilä[1], J. Lötjönen[5], M. Teräs[1], J. Knuuti[1]; [1]Turku PET Centre, Turku University Hospital and University of Turku, FINLAND, [2]Department of Nuclear Medicine, Turku University Hospital, FINLAND, [3]Department of Mathematics and Statistics, University of Turku, FINLAND, [4]University College London, London, UNITED KINGDOM, [5]Knowledge Intensive Services, VTT Technical Research Centre of Finland, FINLAND.

Introduction: In cardiac PET, pulsatile and respiratory motion may cause severe artifacts. Especially when imaging few millimeter targets such as coronary plaques, cardiac tumors or focal inflammations without any motion correction, a few centimeter physical movement of the heart can impair an image quality significantly. In this project, dual gating and motion correction methods for cardiac PET were developed and their technical features were studied. Material and methods: Respiratory gating methods based on spirometry and impedance measurements were developed and tested with cardiac MR and PET imaging. Additionally, three motion correction methods were implemented for cardiac PET/CT imaging. In the first method, dual-gated data from PET images were only used to compensate respiratory and pulsatile motion. In the second method, the respiratory motion correction was implemented by using respiratory gated CT images and pulsatile motion by using solely PET data (CT-PET based method). In the third method, dual-motion correction was carried out by using CT based motion models (CT only method). These techniques were tested using phantom and patient data. Furthermore, the optimal number of dual-gates for cardiac PET was studied. Results: Spirometry based respiratory gating method was found to be feasible in both cardiac MRI and PET studies. The amplitude of spirometry signal correlated well with the respiratory induced movement of heart. Impedance based respiratory gating method worked well especially in time-based gating. The motion correction did not succeed, when only PET data were used for motion modeling. However, CT-PET based and CT-only methods were able to correct respiratory and pulsatile motion efficiently in both phantom and patient studies. The motion was reduced in the patient study from 19 to 9 mm and in the phantom study from 15 to 5 mm. Additionally, the optimal number of dual gates for cardiac PET was found to be 24. Conclusions: Using our dual-gating approach and motion-correction methods, both respiratory and pulsatile motions can be reduced significantly in cardiac PET imaging.

Long-term Prognostic Value of Stress Myocardial Perfusion Imaging and Coronary Computed Tomography Angiography: a Meta-analysis

V. Cantoni[1], R. Green[1], W. Acampa[2], M. Petretta[3], G. De Matteis[1], B. Russo[1], T. Mannarino[1], M. Salvatore[4], A. Cuocolo[1]; [1]Department of Advanced Biomedical Sciences, University of Naples Federico II, Naples, ITALY, [2]Institute of Biostructure and Bioimaging, National Council of Research, Naples, ITALY, [3]Department of Translational Medical Sciences, University of Naples 'Federico II', Naples, ITALY, [4]IRCCS SDN, Naples, ITALY.

Aim: Although stress myocardial perfusion imaging (MPI) by single photon emission computed tomography and coronary computed tomography angiography (CCTA) should be considered complementary, as the anatomical data provided by CCTA differ from the functional information obtained by stress MPI, in clinical these two imaging modalities are alternatively used. Thus, we performed a meta-analysis of published studies, including patients with suspected or known coronary artery disease (CAD), to compare the long-term predictive value for adverse cardiac events of stress MPI and CCTA.Material and methods: An English literature search was performed using the PubMed, Cochrane, Web of Science, and Scopus database to identify articles published between January 2000 and June 2014. To harmonize the predictors of interest, a study was included if all of the following criteria were met: 1) reported a prospective or retrospective analysis of subjects with suspected or known CAD referred for stress MPI to search inducible ischemia or CCTA to detect significant stenosis; 2) provided the unadjusted and/or adjusted hazard ratio (HR) at Cox regression analyses of dichotomous abnormal versus normal perfusion at MPI or coronary stenosis ≥50% luminal narrowing at CCTA; 3) provided primary data on clinical outcomes for adverse events with a follow-up ≥2.5 years; 4) included ≥100 patients.Results: Total of 20 articles (10 MPI and 10 CCTA) were finally included, recruiting 22, 280 patients (13,484 in MPI and 8,796 in CCTA studies). The pooled HR for the occurrence of the primary end point was lower (P=0.04) for MPI (HR 2.60, 95% confidence interval, CI, 2.06-3.29) compared to CCTA (HR 5.70, 95% CI 2.68-12.1). Among the included publications, 4 MPI and 4 CCTA

studies reported the HR for the occurrence of hard events (nonfatal myocardial infarction or cardiac death). The pooled HR was comparable (P=0.11) for MPI (HR 2.75, 95% CI 2.11-3.59) and CCTA (HR 5.34, 95% CI 2.46-11.60) studies. The HR for the occurrence of a combined end point including revascularization was reported in 5 MPI and 6 CCTA studies. The pooled HR was higher (P=0.002) for CCTA (HR 8.27, 95% 3.77-18.14) compared to MPI (HR 2.84, 95% CI 1.68-4.79).Conclusion: CCTA appears more predictive than MPI when coronary revascularization is included in the end point. On the other hand, no differences exist in the prognostic effectiveness of MPI and CCTA for the occurrence of hard events.

OP168

Clinical utilization of submillisievert stress only myocardial perfusion imaging and concurrent coronary artery calcium score: A single institutional experience of a novel cardiac SPECT camera using cadmium zinc telluride (CZT) semiconductor technology

J. Liu, E. Hasche, J. Kilian, H. Dixson, B. Elison, C. Bui, H. Tie, R. Dunn, C. Smillie, Q. Chiam, K. Lee; Bankstown-Lidcombe Hospital, Bankstown, AUSTRALIA.

Aim: To investigate the clinical impact of ultralow dose stress only myocardial perfusion imaging (ULDSO-MPI) and concurrent coronary artery calcium score (CACS) on patients with low pre-test probability for ischaemic heart disease while achieving submillisievert radiation exposures. Material and methods: 120 consecutive patient referrals for ULDSO-MPI with concurrent CACS on the Discovery NM/CT 570c camera (GE Healthcare) were studied. ULDSO-MPI was performed using 100MBq (0.8mSv) Tc-99m sestamibi and 10 minute cadmium zinc telluride (CZT) - SPECT acquisition. CACS was performed using low dose (0.8mSv) prospective ECG gated CT acquisition and adaptive statistical iterative reconstruction (ASIR). CACS CT was synergistically used for SPECT attenuation correction. Outcomes were obtained in 103/120 patients based on cardiology outpatient clinic letters. Results: Technically satisfactory studies were obtained in all patients. Total (ULDSO-MPI+CACS) radiation dose was 1.61±0.11mSv (mean ±SD). All 47 patients with zero CACS had a normal MPI result, and 94 %(44/47) were subsequently discharged from COPCs (defined as no scheduled COPC appointment within the next 12 months). 38/103 patients were started on more aggressive medical therapy. Statistical analysis using Wilcoxon rank sum (Mann-Whitney U) test demonstrated that the patient group started on more aggressive medical therapy was associated with significantly higher CACS (mean CACS = 253) when compared with the group of no change to medications (mean CACS = 28, $p < 0.0001$). Meanwhile, the patient group with ongoing follow up was associated with significantly higher CACS when compared with the discharge from clinic group ($p < 0.001$). Conclusion: Ultralow dose stress only imaging with calcium score is clinically useful and is associated with a very low total radiation dose (1.6 mSv). MPI assesses the short term while the CACS assesses the long term risk for developing ischaemic heart disease. Concurrent zero CACS and normal MPI aid subsequent patient discharge from the COPCs (94% discharge rate). Abnormal CACS leads to more aggressive medical therapy, particularly as the calcium score risk level rises.

OP169

Detection of myocardial ischemia using artificial neural network: different characteristics from conventional defect scoring methods

K. Nakajima[1], S. Matsuo[1], K. Okuda[2], K. Yokoyama[3], H. Bunko[4], S. Kinuya[1], L. Edenbrandt[5]; [1]Kanazawa University Hospital, Kanazawa, JAPAN, [2]Kanazawa Medical University, Uchinada, JAPAN, [3]Matto Ishikawa Central Hospital, Hakusan, JAPAN, [4]Kanazawa Cardiovascular Hospital, Kanazawa, JAPAN, [5]University of Gothenburg, Gothenburg, SWEDEN.

Purpose. Although induced ischemia has been evaluated using stress myocardial perfusion imaging with visual and quantitative scoring methods, a new approach using artificial neural network (ANN) to detect ischemia was developed and its characteristics to identify abnormality were examined. Methods. Patients with coronary artery diseases were selected from 3 hospitals. Mean age was 70±10 years (male 61%) and all patients underwent coronary angiography (0-, 1-, multi-vessel disease (MVD): 25, 29, 52 cases). Patients with old myocardial infarction (OMI, 27%) and coronary revascularization (30%) were included. The training database for the ANN system included normal and perfusion defects, and was classified by experienced physicians, in which 1051 patients (M/F=498/553) were included. Quantification of defects by summed stress/rest/difference scores (SSS, SRS, SDS) were used as a reference, and the normal database using Japanese Society of Nuclear Medicine working group was installed (cardioREPO software). The gold standards were expert consensus of well-experienced nuclear physicians and coronary stenosis of ≥75% or ≥50%. ANN identified abnormal areas and probability (ANN values) in the stress map (ANN stress defect) and difference map between rest and stress (ANN ischemia). Diagnostic accuracy of ANN was compared to conventional visual consensus and scoring methods. Results. The ANN stress

defect value was higher in the consensus defect group than in the no-defect group (0.92±0.11 vs. 0.25±0.32, P<0.0001), and the ANN ischemia was higher in the ischemia group than in the no-ischemia group (0.70±0.40 vs. 0.004±0.032, P<0.0001). Area under the curve with receiver-operating characteristics curve analysis (AUC-ROC) showed comparable diagnostic accuracy between ANN and the scoring methods (0.97 vs. 0.98 for stress defect, and 0.88 vs. 0.94 for ischemia, both P=NS). When diagnostic accuracy was examined with neither OMI nor revascularization they were also comparable (ROC-AUC: ANN ischemia 0.93, ANN stress defect 0.97). The relationship between ANN and scores were not linear, and the ANN increased in the range of SSS and SDS of 0 to 6 rapidly, reaching plateau (nearly 1.00) in the higher score level. Even when coronary stenosis was used as the gold standard of abnormality in patients with neither OMI nor revascularization, sensitivity, specificity and accuracy did not differ significantly among visual consensus, scoring method and ANN methods. Conclusion. ANN provided comparable diagnostic accuracy to the expert interpretation for detection of ischemia even including patients with MVD, OMI and revascularization. The different characteristics from the scoring could provide good adjunctive diagnostic suggestions in clinical practice.

OP170

Nuclear Cardiac Imaging Versus Fractional Flow Reserve in Diagonal Side Branch Ostial Stenosis After Left Anterior Descending Crossover Stenting

S. Fukuzawa, S. Okino, J. Maekawa, S. Ichikawa, N. Kuroiwa, K. Yamanaka, T. Igarashi, M. Inagaki; Funabashi Municipal Medical Center, FUNABASHI, JAPAN.

Background: Although angiographic stenosis of a side branch ostium is frequently observed after stent implantation in a main vessel, the clinical advantages of treating these lesions using complex interventional strategies remain unclear, and such interventions may increase the subsequent risk of adverse clinical events. In addition, these lesions cannot be properly evaluated by conventional coronary angiograms. Objectives: The aim of this study was to compare fractional flow reserve (FFR) and ischemic burden with nuclear cardiac imaging in jailed ostial diagonal lesions after main left anterior descending artery (LAD) crossover stenting. Methods: 38 patients with LAD lesions treated by main LAD crossover single stenting were consecutively enrolled. After successful stenting, FFR was measured at the jailed diagonal side branch. Additional interventions were not performed at the same procedure except TIMI 3 flow of side branch. Intracoronary pressure measurements to determine FFR of the jailed side branch are increasingly performed during coronary angioplasty. Furthermore, one-day stress-rest Tc-99m sestamibi nuclear imaging protocol was used for all patients after procedure within 2 weeks. Results: Among 18 side branches with > 75% diameter stenosis, 6 (33%) had FFR ≤ 0.75, and among 20 side branches with ≤ 75% diameter stenosis, one (5%) had FFR ≤ 0.75 after stent implantation in main vessels. Nuclear study demonstrated inducible ischemic burden (>10%) in only one case of all patients. On the other hand, 26 (68%) patients showed no ischemic area. Clinical follow-up was performed in all patients. Mean duration was 28±9 months. During the follow-up period, one patient of the inducible ischemia underwent side branch stenting and 2 patients underwent TLR because of main stent restenosis. No stent thrombosis was observed in these patients. Conclusion: The finding of the current study is that there is a discrepancy between angiographic percent diameter stenosis and FFR in jailed side branch lesions. Furthermore, nuclear imaging demonstrated that almost of the patients with inadequate FFR of side branch had mild (<10%) ischemic burden and good prognosis.

OP171

In vivo validation of gated myocardial SPECT imaging for quantification of small hearts: comparison with cardiac MRI

C. Kondo, E. Watanabe, M. Momose, K. Fukushima, K. Abe, N. Hagiwara, S. Sakai; Tokyo Women's Medical University, Tokyo, JAPAN.

Aim:In patients with small hearts, defined as an end-systolic volume (ESV) of ≤20 ml calculated using the Quantitative Gated SPECT (QGS) program for gated myocardial perfusion imaging, underestimation of ESV and overestimation of ejection fraction (EF) are frequent and have limited reliability. A newly developed cardiac software, cardioREPO (cREPO, previously named EXINI heart), using novel active shape modeling and volume-dependent edge correction algorithm for left ventricular (LV) delineation, effectively reduces the effects on ESV and EF of a small heart documented on digital phantom experiments (Nakajima K, EJNMMI 2013). The aim of this study was to validate cREPO in vivo for measuring LV volumes and EFs of both small and normal-sized hearts compared with cardiac MRI (CMR). Materials and Methods: We performed stress 99mTc-MIBI SPECT and gated CMR within 30 days interval for 33 patients (mean age, 66 yrs; 19 male) with known or suspected coronary artery disease. Post-processing of resting SPECT data using both QGS and cREPO

provided EF, end-diastolic volume (EDV) and ESV. These results were compared with corresponding data from CMR measured independently by experts in a totally blinded fashion. The following data are expressed as mean±SD (range). Results:The study subjects had body surface area of 1.67±0.17 m2 (1.32-1.98 m2) and consisted of 15 small and 18 normal-sized hearts. CMR gave EFs, EDVs and ESVs of 61%±4% (52%-70%), 127±27 ml (85-191 ml) and 52±17 ml (27-91 ml). QGS gave these values of 68%±10% (43%-86%, p<0.0001 vs CMR), 72±20 ml (42-119 ml, p<0.0001 vs CMR) and 25 ±14 ml (8-66 ml, p<0.0001 vs CMR). cREPO also gave values of 70%±4% (61%-77%, p<0.0001 vs CMR), 87±21 ml (50-131 ml, p<0.0001 vs both CMR and QGS) and 26±8 ml (12-55 ml, p<0.0001 vs CMR). Bland Altman plots showed the deviations (mean±1.96SD) of QGS from CMR of EF, EDV and ESV were 7%±16%, -55±28 ml and -27±23 ml, respectively, and the values of cREPO from CMR were 9%±10%, -41±29 ml and -26±26 ml, respectively. The magnitude of the overestimation of EF by QGS compared with CMR strongly correlated with given EF values (r=0.80, p<0.0001), but no significant correlation was seen with cREPO (r=-0.09, p=0.62). Thus, cREPO provided relatively constant overestimation of EFs by 9% from CMR within the range of EFs in both small and normal-sized hearts. Conclusion:The active shape modeling and volume-dependent edge correction program effectively reduced overestimation of EF of a small heart in vivo.

OP172

Diabetes Mellitus independently determines PET-derived systolic function

L. Juárez-Orozco[1], R. J. J. Knol[2], R. A. Tio[3], S. Lazarenko[2], R. H. J. A. Slart[3], F. M. van der Zant[2]; [1]Rijksuniversiteit Groningen, Groningen, NETHERLANDS, [2]Medical Center Alkmaar, Alkmaar, NETHERLANDS, [3]University Medical Center Groningen, Groningen, NETHERLANDS.

Type 2 diabetes mellitus (DM) has an important role in the development of coronary artery disease (CAD) and may influence systolic function by disturbance of coronary vasculature dilatory capacity. Myocardial perfusion PET is the current reference technique for quantitative evaluation of myocardial blood flow (MBF) and for assessment of the myocardial perfusion reserve (MPR). Moreover, PET can accurately determine systolic function through the left ventricle ejection fraction (LVEF). The present study aimed to evaluate a suspected relationship between DM and systolic function when accounting for MPR and additional cardiovascular risk factors. METHODS: We retrospectively included, with a prospective analysis, 591 patients without previous myocardial infarction, referred for dynamic and gated rest and adenosine stress 13NH3 myocardial perfusion PET between 2012 and 2014. Six patients were excluded for incomplete quantitative perfusion, expressed by MPR, or systolic function expressed by resting LVEF. Clinical records were retrieved for demographic data. MBF and MPR were obtained from the PET data using the SyngoMBF software package. DM was operationalized as a dichotomous variable for presence or absence of the disease. After distribution evaluation of the continuous predictors we performed a bootstrapped multiple linear regression analysis for gender, age, hypercholesterolemia, hypertension, smoking habit, DM and MPR as independent variables and LVEF (expressed as a percentage) as the dependent variable for the model. The statistical analysis was performed using SPSSv.21. P-values ≤ 0.05 were considered statistically significant. RESULTS: Our population (mean age of 66.3±10 years) was composed by 293 males and 297 females. Of these, 16% (94) were smokers, 57.1% (336) had hypertension, 37.6% (221) had hypercholesterolemia, 33.8% (199) had a positive family history for CAD and 15.2% (83) were known with DM. A mean global MPR of 2.17±0.57 and mean LVEF 65.7%±12.2 was measured. Consecutively, multiple linear regression analysis showed a statistically significant relation for age B=6.986 S.E.=1.013 95%CI [5.115, 8.929], p=0.001, MPR B=2.081 S.E.=0.908 95%CI [0.442, 3.713], p=0.021, and the presence of DM B=-3.108 S.E.=1.288 95%CI [-5.674, -0-668], p=0.016. CONCLUSION: There is a significant relationship between DM and PET-derived systolic function in patients without a previous myocardial infarction which persists when accounting for the significant relationship that age and global MPR (along with clinically relevant risk factors) have with LVEF. Our study underlines the importance of DM as a risk factor for deteriorating systolic function. This warrants the need for further research into elucidating the integration of DM and MPR in early clinical decision-making.

OP173

Are myocardial perfusion reserve and LVEF modified by diabetes mellitus? A cardiac PET study.

L. Juárez-Orozco[1], R. H. J. A. Slart[1], R. A. Tio[1], H. H. Boersma[1], A. Ayala-German[2], L. Walls-Laguarda[2], R. A. Dierckx[1], E. Alexanderson[3]; [1]University Medical Center Groningen, Groningen, NETHERLANDS, [2]Universidad Nacional Autónoma de México, Mexico City, MEXICO, [3]Instituto Nacional de Cardiología “Ignacio Chávez”, Mexico City, MEXICO.

Diabetes mellitus (DM) constitutes a chronic degenerative disease with an elevated risk of cardiovascular events. State-of-the-art techniques such as PET myocardial perfusion scanning have

demonstrated that myocardial perfusion reserve (MPR), as well as the left ventricle ejection fraction (LVEF), offer predictive value for adverse cardiovascular events in the setting of coronary artery disease (CAD). Moreover, MPR in spared myocardium (MPR-sm) has shown to be related to systolic function in CAD patients. The present study aimed to evaluate whether the relationship between quantitative perfusion assessed by MPR-sm and LVEF is modified by the presence of diagnosed DM. Methods. We retrospectively included, with prospective analysis, 178 patients (124/54 men/women) who were referred to a PET perfusion scan for known or suspected CAD. There were 60 patients with previously diagnosed DM who were matched to non-diabetic controls (118 patients) according to age, gender, BMI, and size of previous infarction (when present). Other cardiovascular risk factors were comparable. All of the patients underwent a 2-phase (rest and adenosine stress) [13N] Ammonia gated myocardial PET scan. SyngoMBF and QPS-QGS software were utilized for reconstruction and interpretation of the scans. The areas of previous infarction were excluded manually to account for the MPR-sm. After the univariate analysis, we performed a linear regression analysis utilizing the general linear model for LVEF using MPR-sm, DM, and pairing variables. An interaction considering MPR-sm and DM was manually entered in a second step. A p-value<0.05 was considered significant for derived coefficients. Results. Mean age for the diabetic and non-diabetic groups was 66±9 and 65±9 respectively. There was cumulative frequency of 93 (57.8%) with dyslipidemia, 104 (64.6%) with hypertension, 71 (44.1%) of smokers, and 77 (43%) with a previous MI. The univariate analysis for LVEF as the dependent variable revealed a trend towards significance for DM (p=0.06) and a high significance for the MPR-sm (p=0.001). MPR-sm was found to be significant predictor variable for LVEF (p=0.001) while DM resulted not to be significant (p=0.49). The interaction for predictors was performed manually without yielding significance. Conclusion. The presence of DM in patients with known or suspected CAD is not a modifier for the strong relationship between MPR-sm and LVEF. The independent correlation between DM and MPR-sm with LVEF suggest that a possible direct effect of DM on LVEF is outweighed by the effect of MPR-sm. Further studies for gaining insight on the impact of DM in the perfusion-function relationship are warranted.

OP174

Coronary Artery Calcium and Coronary Flow Reserve by Hybrid Rb-82 PET/CT Imaging in Non-diabetic and Diabetic Patients With Normal Myocardial Perfusion

R. Assante[1], P. Arumugam[2], E. Zampella[1], V. Gaudieri[1], C. Nappi[1], T. Mannarino[1], D. Tout[2], M. Larobina[3], B. Russo[1], W. Acampa[3], M. Petretta[4], C. Tonge[2], A. Cuocolo[1]; [1]Department of Advanced Biomedical Sciences, University of Naples Federico II, Naples, ITALY, [2]Nuclear Medicine Centre, Central Manchester University Teaching Hospitals, Manchester, UNITED KINGDOM, [3]Institute of Biostructure and Bioimaging, National Council of Research, Naples, ITALY, [4]Department of Translational Medical Sciences, University of Naples 'Federico II', Naples, ITALY.

Aim: We assessed the relationship between coronary artery calcium (CAC) and coronary flow reserve (CFR) in non-diabetic and diabetic patients with normal stress myocardial perfusion imaging.Materials and Methods: We evaluated 541 consecutive patients (441 non-diabetic and 100 diabetic patients) without a documented history of CAD and normal myocardial perfusion imaging at vasodilator stress Rb-82 PET/CT imaging. The CAC score was measured according to the Agatston method. Resting and hyperemic myocardial blood flow (MBF) and CFR were automatically quantified. Patients were stratified into two groups based on their CAC score (0-99.9 and ≥100). The Spearman correlation coefficient was assessed between continuous CAC score and MBF or CFR values. Univariable and multivariable logistic regression analyses were used to determine the variables associated with reduced (<2) CFR.Results: Among non-diabetic patients, 330 (75%) had CAC <100 and 111 (25%) ≥100, while in diabetic patients 65 (65%) had CAC <100 and 35 (35%) ≥100 ($p<0.05$). CFR was reduced in 54 (16%) non-diabetic patients and in 19 (29%) diabetic patients with CAC <100 ($p<0.05$). In both non-diabetic and diabetic patients, CAC score was inversely correlated with hyperemic MBF ($r=-0.15$ and $r=-0.26$, respectively, $p<0.05$) and CFR (r -0.19 and $r=-0.23$, respectively, $p<0.05$). On the contrary, there was no correlation between CAC and baseline MBF in both non-diabetic and diabetic patients. In non-diabetic patients, univariable analysis demonstrated that age ($p<0.001$), hypertension ($p=0.05$) and CAC score ($p<0.001$) displayed an inverse relationship with CFR, while multivariable analysis indicated that age ($p<0.05$) and CAC score ($p<0.05$) were independently correlated with reduced CFR. In diabetic patients, age ($p<0.05$) and CAC score ($p<0.05$) displayed an inverse relationship with CFR. However, at multivariate analysis only CAC score ($p<0.05$) resulted as independent predictor of reduced CFR in diabetic patients.Conclusions: In diabetic and non-diabetic patients with normal stress myocardial perfusion there is an inverse correlation between CAC score and both hyperemic MBF and CFR that remain also after adjusting for age and conventional cardiovascular risk factors. In diabetic patients without known CAD a reduced CFR could help to identify early structural alterations of the arterial wall.

^{18}F-FDG PET-CT and Radiotherapy Planning in Lung Cancer - Technical aspects and benefits from metabolic radiotherapy planning

J. Pinto[1], L. Vieira[1], D. Faria[2], J. Vale[3], G. Fonseca[3]; [1]Lisbon School of Health Technology, Lisbon, PORTUGAL, [2]Hospital Lusíadas Porto, Oporto, PORTUGAL, [3]Júlio Teixeira S.A – Radioterapia, Oporto, PORTUGAL.

Introduction:18F-FDG positron emission tomography/ computed tomography (PET-CT) has become an integral component of lung cancer staging because it improves the detection of nodal and distant metastases and significantly alters patient man¬agement. PET is more sensitive than computed tomography (CT) for staging, delineation of the extent of malignancy and for the identifi¬cation of distant metastatic disease. The use of Positron Emission Tomography - Computer Tomography (PET-CT) for target volume delineation in radiation treatment planning allows the combination of the anatomical features of CT with the metabolic evaluation provided by PET.The aim of this study is to compare the definition of planning target volume (PTV) using CT versus 18-FDG PET-CT, the impact on the radiotherapy planning and technical implications on daily routine PET-CT procedures in a Nuclear Medicine Department.Material and methods: A total of 20 patients diagnosed with lung cancer of both genders, with ages between 35-85 years old, underwent three-dimensional conformal radiotherapy (3D CRT). In all the patients a CT scan and an 18-FDG Whole Body PET/TC, complemented with additional segmental late images for radiotherapy planning were performed. The delineation of the GTVs was performed by independent observers based on CT only vs PET-CT images. The PTV was created using the same margins for both GTV volumes. PTV was chosen because is the volume used for radiotherapy treatment planning and that influences the patient treatment. Both volumes were compared.Results: Our preliminary results show larger CT-based PTVs, compared with the PET-CT-based PTVs. The average total PTV from the CT and PET-CT scans was 129.87 cm3 and 66,39 cm3 respectively ($p < 0.05$). An average reduction of 38% in size was observed when PET-CT-based PTVs were used.Conclusion: The use of 18-FDG PET-CT allows a better identification of the metabolic disease in Lung cancer patients. In the CT scan radiooncologist while delineating planning volumes tend to include tissue non metabolic active increasing the GTV and as consequence, the PTV. An increase of planning volume may lead to alterations in the treatment schemes and increase in patient comorbidities.

Influence of attenuation correction methods in the renal scintigraphy with 99mTc-DMSA

A. I. Santos[1], **A. Amaro**[2], E. Carolino[2], H. Silva[2], L. Vieira[3], T. F. Vaz[2]; [1]Hospital Garcia de Orta, Almada, PORTUGAL, [2]Escola Superior de Tecnologia da Saúde de Lisboa, Lisbon, PORTUGAL, [3]Escola Superior de Tecnologia da Saúde de Lisboa & Instituto de Biofísica e Engenharia Biomédica, Faculdade de Ciências, Universidade de Lisboa, Lisbon, PORTUGAL.

Introduction: The estimate of relative renal function (RRF) through scintigraphy with dimercaptosuccinic acid labelled with Technetium-99 metastable (99mTc-DMSA) may be influenced by kidney depth (KD), due to attenuation by surrounding soft tissue. The KD is rarely determined and considered for RRF estimate, so other methods are applied to circumvent this problem, namely through calculation of the geometric mean (GM) or by application of empirical formulae. Aim: Identify the influence of different attenuation correction (AC) methods on RRF estimate determined by scintigraphy with 99mTc-DMSA. Materials and methods: Thirty-one patients underwent the same acquisition protocol of 99mTc-DMSA scintigraphy. Two independent Technologists performed the image processing, changing the method applied for RRF determination, namely: Raynaud method, Taylor method, Tonnesen method, GM and without any method of AC (WAC). Each exam was processed three times in the same conditions. To identify the influence of the different AC methods on RRF estimate was applied the Friedman test and to evaluate the association and significance between KD and the variables age, weight and height was used Pearson correlation test. Results: Statistically significant differences were found between the different methods ($p<0.001$), except the comparisons between WAC/Raynaud, Tonnesen/GM and Taylor/GM ($p=1.000$), for both kidneys. A strong positive correlation was found between weight and all the methods of KD estimation. Conclusion: Regarding the three methods of KD calculation (Raynaud, Taylor, Tonnesen), the Taylor method is the closest to the GM. The choice of the AC method influences significantly the quantitative parameters of RRF, that way the method selected should be used wisely and standardized for each department in order to allow comparisons throughout time.

OP185

The role of the Nuclear Medicine Technologists in Cyclotron related Research & Development

P. Costa[1], L. Cunha[2], L. F. Metello[2]; [1]Nuclear Medicine Department, ESTSP.IPP & CADCTR, Vila Nova de Gaia, PORTUGAL, [2]Nuclear Medicine Department, ESTSP.IPP & CADCTR & IsoPor SA, Vila Nova de Gaia, PORTUGAL.

Introduction: Nuclear Medicine is a highly dynamic field, based on synergies between several different scientific fields such as Physics, Chemistry, Biology and Engineering, among others. Over the last decade, several areas of Nuclear Medicine have been particularly active in terms of research. Some examples are developments made in Instrumentation, Image Processing, Therapeutic Applications, Radiopharmacy and Radionuclide Production. It is undeniable that modern research requires multidisciplinary cooperation and collaboration. In this context, advanced practice adequately based on proper education and training of Nuclear Medicine Technologists (NMT) should involve active participation in R&D applied projects. Aim: Using as example one of the fields already mentioned (Radiopharmacy and Radionuclide Production) this paper aims to describe and exemplify the possible role of the Nuclear Medicine Technologist in cyclotron-centered R&D processes. Methods: Examples of research & development projects on Radiopharmacy and Radionuclide Production will be shown, describing the role of the NMT, but also analyzing the interactions with other professionals from the different fields of scientific knowledge needed for the specific requisites of projects being mentioned. Results/Conclusions: Based on our own experience and activity in the field of cyclotron-centered research for Radiopharmacy and Radionuclide Production (including activities at distinct levels in different projects regarding, but not limited to, the development of targetry applied solutions - concerning the targets themselves and all that it is related - the practical methods and solutions to transport the produced activity and/or the recovery, the synthesis and/or purification and distinct processing of radiopharmaceutical products and sub-products, etc.) we consider that multidisciplinarity is indeed a mandatory aspect in research & development processes, at the same time that only highly-educated NMTs might play a "real role" in this specific field essentially due to its versatility and "natural" capacity to integrate basic and applied research, always without losing the focus on the practical questions to be solved/answered and the final applicability of research results, while permanently complying with all the best practices and measures concerning radiation protection, so assuring a safe environmental conditions for themselves as for the remaining health professionals, the members of the public eventually around and the environment itself.

OP186

Occurrence and Characterisation of Perfusion Defects on $^{13}NH_3$ Myocardial PET/CT Due to Side Branch Occlusion After Ramus Descendens Anterior Stenting

H. Kan, R. J. J. Knol, S. V. Lazarenko, M. Wondergem, N. J. Hoogvorst, F. M. van der Zant; MCA, Alkmaar, NETHERLANDS.

Aim: Coronary stenting is frequently accompanied by occlusion of side branches of the targeted coronary artery. This has been shown to induce small reversible or persistent perfusion defects on myocardial perfusion SPECT studies. Data from $^{13}NH_3$ PET/CT studies concerning such perfusion abnormalities after ramus descendens anterior (RDA) stent placement is lacking, and thus this study aimed to analyze the effect of RDA stents on myocardial perfusion as measured by $^{13}NH_3$ PET/CT. Patients and methods: From September 10th 2013 till August 29th 2014, 581 consecutive patients that underwent $^{13}NH_3$ myocardial perfusion PET/CT were prospectively entered in a database. All patients gave written informed consent for usage of their anonymous data. Baseline characteristics and cardiac risk factors were collected. The datasets of patients with a stent in the RDA were evaluated by two experienced readers for the existence of reversible or persisting perfusion defects within the RDA flow territory and subsequently categorized as normal, infarction, ischemia, small persisting defect after stent placement or small amount of ischemia after stent placement. Results: 581 patients {66±10 years (mean±SD), male:female 311(53.5%):270(46.5%)} were included in the database. Of these, 195(34%) had family history of heart disease, 93(16%) were smokers, 125(22%) were diabetic patients, 238(41%) had hypercholesterolemia, 333(57%) had hypertension and 110(19%) had a history of myocardial infarction. A stent in the RDA was present in 53 patients {65±10 years, male:female 33(62%):20(38%)}, of which 29 patients had a stent in the proximal RDA, 18 in the mid-RDA and 6 in both the proximal and mid-RDA. $^{13}NH_3$ myocardial perfusion was scored as normal in 26 (49%), as infarction in 5 (9%), and as ischemia in 2 patients (4%). 6 patients (11%) showed a small persisting defect within the RDA flow territory whereas 14 patients (26%) showed a small area of ischemia in the RDA territory. Conclusion: RDA stents cause small $^{13}NH_3$ myocardial perfusion defects in 38% of the patients of which 70% are reversible.

OP187

Usefulness of simultaneous intermediate-level exercise for dobutamine stress myocardial perfusion imaging.

T. Kasai[1], M. Aiga[1], Y. Iwasaki[2], K. Oshima[1], Y. Fujita[1], Y. Sasaki[1], N. Tanaka[1], A. Yamashina[2]; [1]Tokyo Medical University Hachioji Medical Center, Tokyo, JAPAN, [2]Tokyo Medical University, Tokyo, JAPAN.

Aim: Although dobutamine stress testing is selected when a patient cannot exercise sufficiently, and adenosine is contra indication, not a few cases cannot achieve their target heart rate, resulting in insufficient stress testing. We developed a novel stress method of simultaneous intermediate-level exercise for dobutamine stress myocardial perfusion imaging and assessed the usefulness of this new stress method. Materials and methods: We retrospectively extracted consecutive 44 patients who underwent dobutamine stress myocardial perfusion imaging between September, 2010 and March, 2015. The patients were divided into 2 groups, dobutamine only (22 patients, DOB group) and dobutamine + exercise (22 patients, DOB+EX group). DOB was continuously administered up to 40μg/kg/min. Exercise was performed on a bicycle ergometer up to 75watts as adjusted for each patient tolerance. We investigated the frequency of insufficient stress testing, adverse effects, image quality, hemodynamic kinetics, cumulative administered DOB dose, consumed time for stress testing and compared them between the 2 groups. Results: There was no difference in image quality between 2 groups. Adverse events were occurred 4 cases (18%) in the DOB+EX group during early recovery phase as vasovagal hyperactivity; however, no severe events were demonstrated. Insufficient stress testing were frequent in the DOB group than that in the DOB+EX group (16 (72.7%) vs. 0 (0%); $p<0.001$). Although heart rate was higher in the DOB+EX group (140.5±8.2bpm vs. 117.5 ±17.5bpm, $p<0.001$), there was no difference in peak systolic blood pressure (193.8±22.6mmHg vs. 177.1±30.8mmHg, n.s.). Cumulative DOB dose was higher in the DOB group than that in the DOB+EX group (13.8±6.2mg vs. 6.5 ±3.8mg, $p<0.001$). Heart rate reduction at 2 minutes after termination of stress testing was greater in the DOB+EX group (24.2±9.6% vs. 2.7±6.4%, $p<0.001$). Consumed time for stress testing was shorter in the DOB+EX group than that in the DOB group (586.0±164.3sec. vs. 1240.5±297.0sec, $p<0.001$). Conclusion: DOB+EX reduces insufficient stress testing and contributes to improve the sensitivity of the stress perfusion imaging. In addition, DOB+EX is safe and useful method to improve laboratory throughput.

OP188

Low-dose hybrid CCTA/SPECT image acquisition based on BMI : a case report

V. Weichselbaumer, J. Trinckauf, E. Müller, D. Benz; University hospital Zurich, Zurich, SWITZERLAND.

Aim: In recent years there was a growing interest in the reduction of radiation exposure to patients in diagnostic imaging. The combination of low-dose SPECT myocardial perfusion imaging (MPI) with ultra-low-dose coronary CT angiography (CCTA) allows a comprehensive diagnostic assessment of coronary artery disease (CAD) with low radiation burden. Based on a BMI (body mass index) scale developed at our institution, we have adjusted our scanning protocols, in order to decrease radiation exposure and maintain diagnostic image quality. The aim of this case report is to demonstrate the feasibility of such a low-dose protocol using the BMI scale. Materials and

methods: A 74-year-old female with a BMI of 30.8 presented with new onset of palpitations and an asymptomatic ST-depression during exercise test was referred to our institut for ruling out CAD. The diagnostic work-up started with the acquisition of a CT to measure the calcium score (CT Revolution, GE Healthcare) for risk stratification. Subsequently, an ultra-low-dose CCTA with prospective ECG-triggering was acquired. Technologists at our institution are responsible for selecting BMI adjusted scanning parameters such as kV, mA, contrast agent volume and flow rate. Immediately after the injection of 45ml of Visipaque 320, the CCTA was acquired. Due to calcifications in the right coronar artery (RCA), a low-dose 1-day 99mTc-tetrofosmine stress/rest imaging exam was acquired to exclude a possible hemodynamic relevance of this lesion. Pharmacological stress was done with adenosine, and 163 MBq 99mTc-tetrofosmine was injected at stress midpoint. The99mTc-tetrofosmine dose was prepared by technologists and the acquisition time was calculated using the BMI scale. After a one-hour break stress MPI acquisition (Discovery NM530c, GE Healthcare) was acquired during 912 seconds. Rest MPI was acquired immediately after stress MPI, using 523 MBq 99mTc-tetrofosmine (912 seconds). Results: The total effective radiation dose to the patient was 6.06 mSv, (calcium score: 0.57mSv, CCTA: 0.89mSv, stress/rest SPECT MPI: 1.09 mSv / 3.5 mSv). Image quality was rated as excellent with sharp endocardial and epicardial edge definition, high myocardial count density and uniformity, and without any extracardial background noise. Conclusions: The low-dose SPECT and CCTA protocols provides excellent image quality at low radiation exposure. The BMI scale was developed to optimize work-flow for technologists concerning the calculation of scanning parameters for low-dose hybrid CCTA/SPECT imaging.

OP189

Impact of dynamic acquisition in dual-phase ^{18}flurorocholine PET-CT on radiation exposure of staff and patients

J. BARBIAUX, C. CHNINA, C. HASBROUCQ, S. PETIT, M. THELU, A. BAILLIEZ, T. BLAIRE; GIE HumaniTEP - Hôpital Saint Philibert, LOMME, FRANCE.

Purpose: A dual phase acquisition is usually performed in 18-fluorocholine (FCHOL) PET-CT to assess the prostatic cancer: anearly phase (dynamic acquisition on the pelvis) and a whole body scan (starting 60 minutes after the injection). With recent technological improvements to PET imaging equipment, this study assessed the impact of early phase in patient's irradiation and in staff's exposure. Materials and Methods: Fifty consecutives patients referred for a prostatic cancer in our department were retrospectively included.After injection of 3MBq/kg of FCHOL, the dual-phases acquisitions were performed using a Siemens Biograph mCT Flow 20: the early phase (an 6 minutes early dynamic acquisition on the pelvis, to avoid the bother of the prostatic bed's study before bladder's filing) and the classical whole body acquisition (a study from head to thighs with increased acquisition time on the pelvis and reconstruction in a finer matrix 400 * 400). The CT radiation's exposures (mGy.cm) ofthe patients on both phases were reported and compared. The expositions of the technologists (μSv) for carrying the patients on both acquisitions were measured using an operational dosimetry (APVL, EPD MK2+). Results: For the patients, 263±47 MBq of FCHOL were injected. The mean weight was 85±15 kg. The mean age was 69±7 years. The mean size was 175±7 cm. The mean radiation's exposure was 171±39 mGy.cm and 657±196 mGy.cm for the early and the classical phases respectively. For the technologists, the mean operational dosimetry was 1.55 ±0.22μSv (0.85±0.12μSv in the early phases and 0.70±0.10 μSv in the classical acquisitions). The radiation's exposure of the early phases represented 21% for the patients and 55% for the technologists.Conclusion: The early phases acquisitions represented 21% of the total irradiation for the patients and 55% of the technologists' exposure. It might be interesting to discuss with the medical staff to reduce the systematic realization of the early acquisitions.

OP190

Radiation Dose to the Eye Lens: Does Positioning Really Matter?

C. Baun[1], K. Falch[1], K. D. Nielsen[2], S. Shanmuganathan[1], O. Gerke[1], P. Hoeilund-Carlsen[1]; [1]Odense University Hospital, Odense, DENMARK, [2]University College Lillebaelt, Odense, DENMARK.

Aim: The scan field in oncology patients undergoing eyes-to-thighs PET/CT must always include the base of the scull according to department guidelines. The eye lens is sensitive to radiation exposure and if possible it should be avoided to scan the eye. If the patient's head is kipped backwards during the scan one might avoid including the eye in the CT scan without losing sufficient visualization of the scull base. The aim of this study was to evaluate the possibility of decreasing the radiation dose to the eye lens, simply by changing the head position, when doing PET/CT from the base of the scull to the thigh. Methods and materials: The study was performed using a human like whole body phantom with electronic dosimetry units placed upon each eye to detect the exact radiation dose to the eye lens during each scan. The phantom's head was placed in two different positions, (a) elevated with a pillow below the head (standard), and (b) kipped backwards with the pillow below the neck (kipped). For each head position, CT scans

were repeated 5 times with both a low dose and a high dose CT protocol; in this way, a total of 20 CT scans were performed. Robust standard errors were used in order to account for intragroup correlation due to repeated measurements. Results: Overall, position 'kipped' reduced the radiation dose to the lens, on average by 42.9% or in mean by 1.15 mSv (95% CI: 0.45-1.85; p=0.001) compared to 'standard', i.e., from 2.68 mSv (range 0.67 - 4.68) to 1.53 mSv (range 0.69 - 4.46). With the high dose protocol and position 'kipped', the radiation dose to the lens decreased by 41.5%, on average by 1.52 mSv (95% CI: 0.39-2.64; p=0.008) compared to 'standard', i.e., from 3.66 mSv (range 1.62 - 4.68) to 2.14 mSv (range 1.12 - 4.46). With the low dose protocol and position 'kipped', the decrease was comparable in relative terms: by 45.6% or, in absolute terms on average, 0.78 mSv, (95% CI: -0.05 to 1.61; p=0.07, i.e., from 1.71 mSv (range 0.67 - 2.97) to 0.93 mSv (range 0.69 - 1.66). Not in a single case had position 'kip' the effect that one could not overlook the skull base.Conclusion: These results indicate that it is possible to reduce the radiation dose to the eye lens without loss of diagnostic information in the scan by optimizing positioning of the head.

Do.MoRe: PRRT Dose Response

OP191
PRRT toxicity: DOTATOC versus DOTATATE

M. Sollini[1], E. Grassi[2], F. Fioroni[2], A. Filice[2], V. Ferri[2], A. Frasoldati[2], A. Versari[2]; [1]IRCCS MultiMedica, Sesto San Giovanni, ITALY, [2]Santa Maria Nuova Hospital IRCCS, Reggio Emilia, Reggio Emilia, ITALY.

Aim: Many radiolabeled somatostatin analogues with different affinity profiles for somatostatin receptor subtypes and different biological half-time (63 hours for DOTATOC and 81 hours for DOTATATE) have been employed in Peptide Receptor Radionuclide Therapy (PPRT). We aim to compare PRRT toxicity profiles of DOTATOC and DOTATATE radiolabeled with 90Y or 177Lu in patients with neuroendocrine tumors (NET). Materials and methods: we retrospectively evaluated 16 NET patients of whom 8 treated with 90Y/177Lu-DOTATOC (group 1) and 8 treated with 90Y/177Lu-DOTATATE (group 2) with comparable characteristics (risk factors, number of cycles, cumulative administered activity). Patients were blinded selected (independently from acute and chronic/long term toxicities as well as outcome). Risk factors for PRRT were recorded. 3D-dosimetry of each patient was calculated at organ-level with OLINDA/EXM software. Both BED of kidneys and adsorbed dose of bone marrow were calculated. Haematological parameters including WBC, Hb, PLT and creatinine were recorded to assess acute and chronic toxicity according to CTAE v4.0. Results: Hypertension and/or diabetes were present in 3 patients of each group. Patients of both groups received a median of 4 administrations (range 3-6). The mean cumulative administered activities were 4847 ±4366 MBq and 5365±4107 MBq for 90Y-DOTATOC and 90Y-DOTATATE, respectively (p=0.8) and 12506 ±8362 MBq and 10545±4551 MBq for 177Lu-DOTATOC and 177Lu-DOTATATE, respectively (p=0.5). At least one adverse event (leukopenia, anemia, thrombocytopenia, renal failure) was observed in 7/8 and 8/8 patients, in group 1 and 2 respectively. Overall, in group 1 25 adverse events (grade 1-2) occurred and in 12/25 (48%) adverse events were chronic/long term (G1-2 leukopenia=3, G1 anemia=4, G1 thrombocytopenia=2, G1-2 renal failure=3). Overall, in group 2 52 adverse events (grade 1-4) occurred and in 9/52 (17%) adverse events were chronic/long term (G1 leukopenia=1, G1-G2 anemia=5, G1 thrombocytopenia=1, G1-4 renal failure=2). In group 2 transient acute toxicity between administrations occurred more frequent compared to group 1 (43 versus 13 adverse events, p=0.0046). BED of kidney resulted 32±20 Gy in group 1 and 49±23 Gy in group 2 (p=0.14) while bone marrow adsorbed dose was 0.177±0.113 Gy in group 1 and 0.411 ±0.183 Gy in group 2 (p=0.008). Conclusion: our results suggest a major number of adverse events during PRRT using DOTATATE than DOTATOC although in case of DOTATOC we observed a more frequent chronicity/long term mild toxicity (48% versus 17%). No cases of severe haematological disease (i.e. myelodysplasia) were observed while chronic renal failure requiring dialysis occurred in one patient of group 2.

OP192
[^{177}Lu-DOTA]-D-Phe$_1$-Tyr$_3$-Octreotide (^{177}Lu-DOTATOC) for Peptide Receptor Radiotherapy in Patients with Advanced Neuroendocrine Tumours: A Retrospective Phase II Study of Efficacy and Safety

H. R. Kulkarni[1], R. P. Baum[1], A. W. Kluge[2], M. Sayeg[1], U. Schorr-Neufing[2], K. Niepsch[1], N. Biterlich[2], C. van Echteld[3]; [1]Zentralklinik Bad Berka, THERANOSTICS Center for Molecular Radiotherapy and Molecular Imaging (PET/CT), Bad Berka, GERMANY, [2]ABX-CRO GmbH, Dresden, GERMANY, [3]ABX-CRO, Dresden, GERMANY.

Background: To evaluate efficacy and safety of ^{177}Lu-DOTATOC as agent for peptide receptor radiotherapy (PRRT) of advanced neuroendocrine tumours (NET). Material and methods: Fifty-six subjects with metastasized and progressive NET (50% midgut, 26.8% pancreatic, 23.2% other primaries) were included in prospective database and retrospective analysis was performed. Subjects received on average 2.1 (range 1 - 4)

cycles of ^{177}Lu-DOTATOC (median administered activity 7.0 GBq) at three-monthly intervals. Efficacy was analyzed based on RECIST and by number of treatment cycles and histology. Results: In the total population, median progression-free and overall survival was 17.4 and 34.2 months, respectively. Repeatedly treated patients had an Overall progression free survival of 30.2 months. Objective response rate (complete or partial) was 33.9%, while disease control rate was 66.1%. A high number of complete responses (16.1%) was observed, 78% of which were ongoing at the end of the Observation period. 14% of subjects required more than one cycle to induce an Initial response. In 32% of responders, it took four to eight months from the first PRRT cycle, before an initial response could be documented. After initial response, morphological outcome may improve for up to 20 months after the last PRRT. In 47% of subjects it took more than 9 months from start of PRRT until an objective response occurred. No SAE, and only a single case (1.8%) of self-limiting grade 3 hematotoxicity was observed. No renal toxicity was found, although 19.6% of subjects had mild renal insufficiency at baseline. Conclusions: ^{177}Lu-DOTATOC is a novel agent for PRRT with unusual potential to induce objective response in progressive neuroendocrine tumours and long lasting disease control, even when administered at moderate activity doses. Efficacy was highest when the agent was administered in repetitive cycles, indicating that efficacy should be established only after Administration of the prescribed dose. With only 6.2% non-responders, the overall disease control rate (DCR) was 93.8%, compared to 80.3-85.0% reported for ^{177}Lu-octreotate. This difference in DCR between the peptides is accounted for by an about ten-fold higher rate of subjects experiencing a complete response following ^{177}Lu-DOTATOC. In the subgroup of patients with GEP-NET, the proportion of complete responders was 25%, which is the highest value ever reported to date. A particularly high therapeutic index is suggested by the observed safety profile, also in subjects with a priori reduced bone marrow or renal function, which reflects a uniquely low uptake of ^{177}Lu-DOTATOC by normal organs.

OP193

Long term survival analysis after i.a. 90Y-DOTATATE PRRT, in patients with non-resectable, advance progressive liver dominant neuroendocrine neoplasms.

M. L. Nowicki[1], S. J. Konsek[2], L. Jaskiewicz[2], M. Mol[3], A. Sankowski[1], J. R. Buscombe[4], L. Bodei[5], R. Mikolajczak[6], **J. B. Cwikla**[2]; [1]Department of Radiology and Diagnostic Imaging, Hospital Ministry of Internal Affairs & Administration, Warsaw, POLAND, [2]Department of Radiology, Faculty of Medical Sciences, University of Warmia and Mazury, Olsztyn, POLAND, [3]Radiology and Diagnostic Imaging, Medical Center for Postgraduate Education, Warsaw, POLAND, [4]Department of Nuclear Medicine, Addenbrooke's Hospital, Cambridge, UNITED KINGDOM, [5]Division of Nuclear Medicine, European Institute of Oncology, Milan, ITALY, [6]Centre POLATOM, National Centre for Nuclear Research Radioisotope, Otwock, POLAND.

Purpose: To evaluate long term survival in group of patients with non-resectable, liver dominant and progressive neuroendocrine neoplasms after i.a. 90Y DOTATATE peptide receptor radionuclide therapy (PRRT) in gastroenteropancreatic neuroendocrine tumours (GEP-NET). Patients and Methods: The study group: 38 patients, 17 female, mean age 56.2. All with histological proven extensive non-resectable GEP-NET. Half of them with secretor tumours. All had documented DP (RECIST and/or clinical in case or secretor tumours) with relapse on previous therapy. 22 pts with initial i.a. PRRT after relapse of chemo and somatostatin analogues (SST) therapy, others 16 pts had previous i.v. PRRT. Overall 104 therapy session using i.a. 90Y-DOTATATE performed. Initial clinical tumour responses assessed, 6W after therapy and then after each of the 3M intervals of follow-up. The objective tumour response was classified according to RECIST, initially 6W and then after each of the 6M. Adverse Events (AE) of therapy were evaluated using CTCAE NCI (ver. 4.0). Overall survival (OS) and progression free survival (PFS) were evaluated using Kaplan Meier methods. Results: The median OS and PFS for all pts were 39.0M and 24.5M, in group with initial i.a. PRRT were 50.0 and 28.5M in those with previous i.v. PRRT were 20.5 and 12.0M. The clinical response including performance status (PS), initial and 6W after PRRT were significant improved consider all pts and in both groups. ($P<0.05$). Clinical response at 6W seen as PR 29, SD 7 and 2 had DP. At 6M after treatment 27 had PR, 6 SD and 4 DP. After 12M 24 had PR 4 SD and 6 DP. After 24M 11 had PR, 9 SD and rest 6 developed DP. Radiological response (RECIST) at 6W after PRRT was noted in 3 subjects, 33 pts had SD, after 6 M of follow-up 8 had PR, 28 had SD and rest 4 developed DP. After 12M 8 pts had PR, 23 pts had SD and 4 had DP. After 24M, PR was noted in 4, 16 SD and 3 DP. Conclusion: Intra-arterial PRRT using 90Y-DOTATATE seems to be effective in patients with extensive, liver dominant, non-resectable and progressive GEP-NET. Especially as initial therapy after relapse of other therapy options. Could be used as alternative therapy approach in those after i.v. PRRT, who relapse and whom i.v. PRRT could be cause of AE (kidney and bone marrow). Objective response of PRRT, base on RECIST, underestimate benefits of this type of therapy.

OP194

Early assessment of renal impairment in patients undergoing Peptide Receptor Radionuclide Therapy evaluated by MAG3 renal scintigraphy

R. A. Werner[1,2], S. Beykan[1], C. Lapa[1], C. Bluemel[1], U. Eberlein[1], T. Higuchi[1,2], H. Wakabayashi[1], K. Herrmann[1,3], A. K. Buck[1], M. Lassmann[1], H. Hänscheid[1]; [1]Department of Nuclear Medicine, University Hospital Würzburg, Würzburg, GERMANY, [2]Comprehensive Heart Failure Center, University Hospital Würzburg, Würzburg, GERMANY, [3]Department of Molecular and Medical Pharmacology, David Geffen School of Medicine at UCLA, Los Angeles, CA, UNITED STATES.

Objectives: Due to the potential nephrotoxicity of Peptide Receptor Radionuclide Therapy (PRRT), pre-therapeutic assessment of kidney function is mandatory. Radiation damage of irradiation is the proximal tubuli reabsorbing the radionuclide and the interstitium retaining the radioactivity. Therefore, kidney function test measuring tubular extraction, like mercaptoacetyltriglycine (^{99m}Tc-MAG3), provides additional information in early stages of suspicious renal failure. The aim of this study was an early assessment of renal impairment after treatment with ^{177}Lu-octreotide to investigate the potential loss of kidney function as a function of the administered activity. Materials and Methods: From March 2011 to December 2014, renal impairment was analyzed prior to 136 treatments (32 patients) using ^{99m}Tc-MAG3 clearance (mean follow-up, 366 ± 201 days). Subsequently, PRRT was performed with a mean cumulative activity of 32.2 GBq ^{177}Lu-octreotide (3-7 cycles, standard intervals of 3 months). The ratio of the MAG3 tubular extraction rate (TER) to TER of lower limit (RaTER) was calculated and analyzed as a function of the cumulative administered activity by linear regression analysis. Results: Prior to PRRT, 12 patients showed impaired renal function and 20 patients demonstrated normal kidney function, as indicated by ^{99m}Tc-MAG3 renal scintigraphy (mean TER, 233.5 ± 52.6 ml/min/1.73 m^2). RaTER was 131 ± 0.25 %. Linear regression analysis revealed a median shift of renal function of -0.03% per administered GBq (quartile, -0.34%/GBq, +0.14%/GBq). The following equation was utilized: (relative change in TER per GBq of ^{177}Lu) = 0.0088 - 0.0106 x (initial TER/TER$_{lower\ limit}$). Furthermore, negative gradients showing a high loss of TER per administered activity were observed in patients with a good kidney function whereas in the cohort with initial renal impairment the TER remained almost constant. To illustrate this, we found in 13 patients having an initial TER of <1.3*TER of lower limit that the worst reduction of kidney function was only 0.21% per administered GBq. Conclusion: Only patients with an appropriate kidney function prior to the start of PRRT seem to be at risk of developing renal impairment in the course of therapy. On the other hand, an initially reduced ^{99m}Tc-MAG3- clearance prior to the first treatment cycle seems not to be an exclusion criteria for PRRT. In this study investigating the early assessment of renal function by ^{99m}Tc-MAG3 renal scintigraphy, a low risk of PRRT related renal damage was demonstrated even in a long-term follow-up over one year.

OP195

Super-selective Hepatic Arterial Infusions of n.c.a. Lu-177-Dotatoc in Inoperable Neuroendocrine Liver Metastases of Gastro-Entero-Pancreatic (GEP) Tumors; Preliminary Results

G. S. Limouris[1], N. Trompoukis[1], V. Poulantzas[1], I. Karfis[2], A. Chatzioannou[1], M. Lyra[1], V. Michalaki[3], N. Triantaphyllou[4], G. Nikou[5], M. Paphiti[6], V. R. McCready[6], L. Moulopoulou[1]; [1]Nucl Med Div-1st Radiology Dept , "Aretaieion" Hospital, Athens University Medical Faculty, Athens, GREECE, [2]Nuclear Medicine Dept, Institute "Bordet", Brussels, BELGIUM, [3]Department of Surgical Oncology, "Aretaieion" Hospital, Athens University Medical Faculty, Athens, GREECE, [4]Neurology Dept, 'Aeginiteion" Hosp, Athens Univ Medical Faculty, Athens, GREECE, [5]Gastrointestinal Div, I Dept of Propedeutic Internal Medicine "Laikon" Hospital, Athens, GREECE, [6]Nuclear Medicine Dept, Royal Sussex County Hosp, Brighton, UNITED KINGDOM.

Aim: To evaluate the effectiveness of non carrier added (n.c.a.) Lu-177 DOTA-TOC in inoperable liver metastases, positive for sst2 receptor overexpression (verified by Octreoscan and confirmed by biopsy) due to neuro-endocrine gastro-enteropancreatic (GEP) tumours. Lu-177 DOTA-TOC has been infused after selective catheterization of the hepatic artery ('ARETAIEION' PROTOCOL), minimising in parallel the toxicity of non-target tissues.Materials and Methods: The average dose per session to each patient (9 pts so far in total) was 7.3±2.3 GBq. Repetitions did not exceed 6-fold with treatment intervals of 8-11 weeks, to avoid stunning effect. Response assessment was classified according to the therapeutic benefit. Absorbed doses delivered to metastases, kidneys and red marrow was calculated according to MIRD scheme and perfoermed using OLINDA 1.1 software. The derived values were correlated to the Response Evaluating Criteria in Solid Tumours (RECIST). CT/ MRI scans were performed as baseline before, during and after the end of treatment and monthly ultrasound images for follow-up estimation and measurements. Toxicity (World Health Organization criteria) was measured using blood and urine tests of renal, hepatic and bone marrow function.Results: None of the patients resulted complete response (0.0%); partial response was assessed in 6 (66.0%) and disease stabilization in 3 (34.0%). An 8-month median survival time was estimated for all patients, so far. Six

of 9 (66.0%) showed a mean target diameter shrinkage ranging from 32% to 46%. The organ average radiation dose estimation was found as follows: (a) Liver Tumor 3.0-9.9mGy/MBq, (b) Liver 0.03-0.1 mGy/MBq, (c) Kidneys 0.03-0.4 mGy/MBq, (d) Spleen 0.02-1.2 mGy/MBq and (f) Bone marrow 0.008-0.05 mGy/MBq. The average absorbed dose per session to a tumor for a spherical mass of 20 gr was estimated to be 9.3 mGy/MBq, depending on the histotype of the tumor. WHO toxicity grade 2 erythro-, leuko- and thrombo-cytopenia occurred in 2 (22.0%) cases observed about after the 3rd session.Conclusion: In unresectable metastatic liver lesions positive for somatostatin receptors repeated, trans-hepatic high doses of n.c.a. Lu-177 DOTA-TOC resulted in a more than promising therapeutic outcome with a partial response in approx 66% of the treated patients. Given the loco-regional modality character of the administration technique, no nephrotoxicity has been so far observed.

OP196

Relationship between baseline GFR, [Lu-177] -DOTATATE Clearance and Radiation Dose to Kidneys During Radionuclide Therapy for Somatostatin-Expressing Tumours

D. L. Bailey[1], T. M. Hennessy[2], K. P. Willowson[2], D. L. Chan[1], G. P. Schembri[1], A. Aslani[1], N. Pavlakis[1]; [1]Royal North Shore Hospital, Sydney, AUSTRALIA, [2]University of Sydney, Sydney, AUSTRALIA.

AIM: To examine the relationship between glomerular filtration rate (GFR) and clearance of therapeutic non-carrier added [Lu-177]-DOTATATE (nca-LuTATE) for treatment of neuroendocrine tumours (NETs) and meningiomas expressing somatostatin receptors, and to examine the impact on radiation dosimetry to the kidneys.MATERIALS AND METHODS: All data were acquired on SPECT/CT cameras (Siemens Symbia.T6 and Intevo) using medium-energy collimation and a single photopeak (208 keV ±10%). The accuracy of our whole body (WB) planar imaging and quantitative SPECT/CT (qSPECT) data have previously been validated to within ±10%. Images were acquired immediately after injection of the nca-LuTATE (ITG/ANSTO and Auspep) and at 4, 24 and 96 or 120 hrs post-injection. Whole body clearance was assessed with planar imaging and kidney uptake was measured with qSPECT. The qSPECT data were input to OLINDA/EXM 1.1 for estimation of kidney dosimetry. A total of 36 treatments in 12 subjects were evaluated with this protocol. Subjects were administered a mean of 7.8 GBq (range 6.2 - 8.7 GBq) of nca-LuTATE.RESULTS: A bi-exponential fit to the WB data demonstrated a fast component of clearance of 2.1±0.6 hrs and a slow component of 58.1±7.2 hrs. Baseline GFR showed a good correlation with the fast component when fitted with an exponential curve (R^2=0.74) but was unrelated to the slow component. Radiation dose estimated to the kidneys from qSPECT likewise demonstrated a significant dependence on GFR with slower clearance rates corresponding to higher kidney dosimetry.CONCLUSION: Baseline GFR affects the fast component of clearance of nca-LuTATE and impacts on the radiation dose received by the kidneys. Radiation dose to the kidneys can almost double when GFR is < 60 ml/min/1.73m^2 compared to a GFR of > 100. Individualisation of patient treatments should consider this when aiming to maximise therapeutic efficacy

OP197

Recurrent glioblastoma multiforme - local alpha emiters targeted therapy with 213Bi-DOTA-substance P

L. Królicki[1], A. Morgenstern[2], **J. Kunikowska**[1], H. Koziara[3], B. Królicki[3], M. Jakuciński[4], D. Pawlak[5], C. Apostolidis[2], F. Bruchertseifer[2]; [1]Nuclear Medicine Department, Medical University of Warsaw, Warsaw, POLAND, [2]European Commission, Joint Research Centre, Institute for Transuranium Elements, Karlsruhe, GERMANY, [3]Department of Neurosurgery, Institute of Psychiatry and Neurology, Warsaw, POLAND, [4]Department of Nuclear Medicine, Brodnowski Hospital, Warsaw, POLAND, [5]Radioisotope Centre POLATOM, National Centre for Nuclear Research, Otwock, POLAND.

Glioblastoma multiforme (GBM) is the most common and malignant primary brain tumor. The median survival time is 14.6 months from time of diagnosis, in spite of aggressive surgery, radiation therapy and chemotherapy. Only 3 to 5% of patients survive more than three years. Recurrence of GBM is nearly universal, confers a dismal prognosis with a 6-months progression free survival (6M-PFS) rate of 15% to 21% and a median survival of 6.2 months. Advancements in the past decades have not significantly increased the overall survival of patients with this disease. GBM has been demonstrated NK-1 receptor system and substance P can be used as a ligand for targeted therapy. Alpha emitter, like 213Bi offers the new potential for selective irradiation of tumors, with minimizing damage to adjacent tissue.Material and methods:21 patients with primary recurrent glia tumor IV after standard therapy were included in the study during two years. Following intracavitary or intratumoral insertion of 1-2 catheter systems, patients were treated with 1-8 doses of 2 GBq 213Bi-DOTA-Substance P (213Bi-SP) in intervals of 2 months. 68Ga-DOTA-Substance P (68Ga-SP) was co-injected with the therapeutic doses to assess biodistribution using PET/CT. Therapeutic response was monitored with MRI. Study was approved by the ethical committee of the Medical University of Warsaw.Results:Treatment with activity up to 13 GBq 213Bi-SP was tolerated well with only mild transient adverse

reactions: in 1 patient transient increase of focal neurological symptoms and in 3 patients episodes of epileptic seizures several days after treatment. PET/CT imaging showed high retention of the radiolabeled peptide at the tumor site.Out of 21 evaluable patients, 17 progressed within the follow-up period, 5 of them are alive at the end of follow-up. Four patients were excluded from evaluation due to lack of data. Median progression free survival was 3.7 months, with a 6 months progression free survival rate of 19% . The median overall survival from the first diagnosis was 25.2 months, and from the start of 213Bi-SP was 6.5 months. Follow up of therapeutic responses and toxicity is continued and patient recruitment is ongoing.Conclusions:Treatment of recurrent GBM with 213Bi-SP is safe and well tolerated. Targeted alpha therapy with 213Bi-SP may evolve as a promising novel option for treatment of recurrent GBM.

Non-invasive determination of the Beta Bell Mass with ^{111}In-exendin-3 in a Rat Model of spontaneous Type 1 Diabetes

L. Joosten[1], M. Brom[1], D. Bos[1], C. Frielink[1], P. Hanneke[2], O. Boerman[1], M. Gotthardt[1]; [1]Radboud university medical center, Nijmegen, NETHERLANDS, [2]GROW mumc, Maastricht, NETHERLANDS.

Aim Thebeta cell mass (BCM) plays a key role in the development and progression ofdiabetes, but the onset of beta cell loss and the relationship between loss ofbeta cell mass and beta cell function still needs to be unraveled. Anon-invasive method to determine the BCM *invivo* would allow measurement of the BCM during the development andprogression of type 1 and 2 diabetes. Exendin-3 is a stable glucagon-likepeptide 1 (GLP-1) analogue with high affinity for the glucagon-like peptide-1receptor specifically expressed on beta cells. In this study we investigatedthe potential of ^{111}In-exendin-3 to determine the BCM *in vivo* in a rat model that closelymimics the development of type 1 diabetes in humans: BioBreeding Diabetes Prone(BBDP) rats. In this model the potential of SPECT, the relationship between theBCM, exendin uptake in the pancreas and inflammation of the islets ofLangerhans (insulitis) were investigated.Materials and Methods BBDPrats (n = 45) of 4-18 weeks of age were injected intravenously with 15 MBq ^{111}In-exendin-3.SPECT/CT images were acquired 1 h p.i. and the animals were euthanized afterSPECT/CT acquisition. The biodistribution of the tracer was determined and thepancreas was used to determine the BCM by morphometric analysis and degree of insulitis.Results WithSPECT the pancreas in rats was visualized. In healthy rats (4 weeks) efficientaccumulation of ^{111}In-exendin in the pancreas was observed (0.29 ±0.03 %ID/g). In severely diabetic rats (18 weeks) pancreatic tracer uptake wassignificantly reduced with more than ninety percent ($p=0.0004$). The uptake ofthe tracer correlated with BCM (mg) (Pearson $r = 0.80$, $p < 0.0001$). *Ex vivo* autoradiography showed high accumulationof ^{111}In-exendin-3 in the islets of Langerhans in healthy rats andvery low accumulation in the exocrine pancreas. The accumulation in theendocrine pancreas was reduced in rats with beta cell loss and in severelydiabetic rats, with no insulin-positive cells, tracer uptake in the pancreas wasundetectable by autoradiography. Furthermore, insulitis did not have an influenceon the uptake of exendin in the pancreas.Conclusion Inconclusion, in a rat model of type 1 diabetes, closely mimicking the humandevelopment of type 1 diabetes, the BCM can be monitored with ^{111}In-exendin-3SPECT. These results indicate that ^{111}In-exendin-3 is a promising tracerto determine the BCM during the development of type 1 diabetes in patients,without interference of severe insulitis.

OP199

Preclinical imaging of the co-stimulatory ligands CD80/CD86 with 111In-DOTA-Belatacept in oncology and atherosclerosis

A. Müller Herde[1], R. Meletta[1], P. Dennler[2], E. Fischer[2], R. Schibli[1], S. D. Krämer[1]; [1]ETH Zurich, Zurich, SWITZERLAND, [2]Paul Scherrer Institute, PSI-Villigen, SWITZERLAND.

Aim: The co-stimulatory ligands CD80 and CD86 play a crucial role in the initiation and maintenance of an immune response and are found on activated antigen presenting cells (APCs). The human derived Raji cell cell line, originated from Burkitt's lymphoma, is associated with a frequent expression of CD80 and CD86. In the context of atherosclerosis, we identified CD80 and CD86 on APCs with significant higher levels in vulnerable plaques [1]. We propose, CD80 and CD86 as promising targets for imaging inflammation. In a proof-of-principle study, the fusion protein Belatacept (Nulojix®), containing the extracellular portion of CTLA-4 as binding motif, was labeled with indium-111. We analyzed the in vitro stability of this radiotracer and evaluated it in mice bearing CD80/CD86-positive Raji xenografts and in a mouse model of atherosclerosis (ApoE KO). Material and methods: Commercially available Belatacept was conjugated with p-SCN-Bn-DOTA, radiolabeled with In-111 and purified by size-exclusion chromatography (SEC). Stability was investigated after incubation in human or mouse plasma at 37 °C up to 72 h by SEC. CD1 nude mice bearing Raji xenografts and ApoE

KO mice were injected i.v. with 10 MBq 111In-DOTA-Belatacept (25 μg, baseline). Blockade animals simultaneously received unlabeled Belatacept (500 μg). In vivo and ex vivo SPECT/CT scans or biodistribution studies were performed 48 h post injection. Oil red o staining was performed with excised blood vessels to visualize plaque lipids. Results: 111In-DOTA-Belatacept was successfully produced in 73-78% radiochemical yield. 82% of labeled fusion protein remained intact after 72 h of incubation in plasma. In vivo, 111In-DOTA-Belatacept accumulated in Raji xenografts and a reduced accumulation was determined under blockade conditions. These results were confirmed by biodistribution revealing a significant reduction in blockade animals. Ex vivo SPECT scans of the aortic arch and the carotids of ApoE KO mice showed a high accumulation in atherosclerotic plaques and a reduced signal under blockade conditions. Tracer accumulation and plaque localization determined by oil red o staining were consistent. Conclusion: The co-stimulatory ligands CD80 and CD86 are promising targets for the non-invasive imaging of activated immune cells.111In-DOTA-Belatacept accumulates specifically in human derived Raji lymphoma xenografts in vivo and binds to inflammatory plaques in a mouse model of atherosclerosis. OP200

Initial experiences with the Mediso nanoSCAN preclinical SPECT/MR

M. Segbers[1], J. C. Haeck[1], I. L. Bakker[1], J. de Swart[1], M. Kovács[2], M. R. Bernsen[1], M. de Jong[1]; [1]Erasmus Medical Center, Rotterdam, NETHERLANDS, [2]Mediso Medical Imaging Systems, Budapest, HUNGARY.

Aim: SPECT and MR imaging are for the first time combined in a single hybrid platform: the Mediso nanoScan SPECT/MRI (Mediso, Budapest Hungary). Combining MRI and SPECT could improve localization of the radioactivity in small animals and aid in organ delineation for biodistribution in vivo and pharmacokinetic analysis, as MRI is well known for its superior soft tissue image contrast compared to CT. In this study the first in vivo images were acquired using different tracers. Materials and methods: System specifications: A 1 Tesla horizontal bore permanent magnet with 500mT/M gradients has been coupled in line with a multi-pinhole SPECT subsystem with four rotating 9.5mm NaI detectors. For MR image acquisition a 35mm-diameter solenoid coil was used. Collimators with 64 pinholes of 1.7mm diameter were used and all SPECT acquisitions covered in approximately 7cm the entire body using spiral scanning with step and shoot (rotation in steps of 12.9 degrees). Images of C7Bl/6 mice were acquired after injection with 42MB 99mTc-MDP and 23MBq 99mTc-DMSA. MRIs were acquired with a T2-weighted Fast Spin Echo (FSE) using TR/TE=4377/88.5, 0.27x0.27x0.8mm voxels in 7 minutes and a T1-weighted Gradient Echo using TR/TE=15/3, 0.15x0.15x0.6mm voxels in 11 minutes. The acquired MR images covered the SPECT FOV. PC3 tumor bearing mice were scanned ex vivo 24hours after injection with 25MBq 111In-JMV4168; a gastrin-releasing peptide receptor (GRPR) antagonist that binds to the GRP receptors of the PC3 tumor. SPECT was combined with a T2-weighted FSE using TR/TE=4000/25 and 0.27x0.27x1mm voxels acquired in 10 minutes. Basic MR image quality was determined by signal to noise ratios (SNR) of various tissues. Results: The 99mTc-MDP scan clearly showed the expected tracer uptake in the bones in excellent detail. 99mTc DMSA showed the expected high tracer uptake in the kidneys that could be clearly localized to the renal cortex on the T2-weighted MRI overlay. The 111In-JMV4168 scan showed expected high tracer uptake in the tumor and much lower uptake in the kidneys. Overall, MRI SNR was tissue dependent and varied between 7.2 for muscle and 28 for tumor. Conclusion: The Mediso nanoScan SPECT/MRI is capable of generating visually qualitative and well interpretable SPECT/MR images. The MR images show detailed anatomy within soft tissues and aid tremendously in localization of radioactive tracer uptake.

OP201

Noninvasive visualization of microRNA by Tc-99m radiolabeled anti-microRNA oligonucleotide in tumor xenografts

L. KANG; PEKING UNIVERSITY FIRST HOSPITAL, BEIJING, CHINA.

Introduction: MicroRNAs have been considered as important biomarkers for malignant tumors. Although various optical imaging methods have been developed for the noninvasive detection of microRNAs, they were generally limited in penetrated ability, genetic modification, and potential toxicity. In this study, we firstly used a radionuclide-based imaging method for the noninvasive visualization of overexpressed miR-21 in tumor bearing mice. Methods: MiR-21 targeted anti-miRNA oligonucleotide (AMO) with partial 2'-O-methyl and phosphorothioate modification was designed and synthesized. Technetium-99m (99mTc) labeled AMO was prepared via the conjugation with NHS-MAG3. 99mTc-AMO was evaluated for its stability, inhibitory ability and cellular uptake in vitro, and further in vivo distribution and imaging in multiple kinds of tumor xenografts. Results: 99mTc-AMO was prepared with high labeling efficiency and specific activity. 99mTc-AMO inhibited miR-21 and up-regulated the expression of PTEN. Fluorescence labeled AMO displayed specific and durable distribution in tumor cells. Further, in tumor

bearing mice, 99mTc-AMO showed significant more accumulation in miR-21 overexpressed tumors than control probe, which suggested the effective delivery of 99mTc-AMO in miR-21 over-expressed tumors. Conclusions: This study supports the effectiveness of 99mTc radiolabeled AMO in the noninvasive visualization of miR-21 in malignant tumors and suggests a potential candidate for tumor imaging.

OP202

Quantitative and longitudinal SPECT imaging of intramuscular transplanted islets of Langerhans using [123I]IBZM

S. M. A. Willekens, I. van der Kroon, D. Bos, L. Joosten, C. Frielink, O. C. Boerman, M. Brom, M. Gotthardt; Radboud university medical center, Nijmegen, NETHERLANDS.

Aims: Besides insulin therapy, pancreatic islet transplantation is considered one of the most promising therapies for type 1 diabetes. Despite improved immunosuppressive therapy, islet transplantation still results in short term insulin independence. A non-invasive imaging method to monitor the viable transplanted islets might provide insight in the faith of the islets after transplantation. Moreover, it could offer the possibility to evaluate therapeutic interventions that might improve long term transplantation outcome. Dopamine 2 (D2) receptors are expressed on beta cells and are therefore a suitable target to monitor islet grafts. Here, we investigated the use of the D2 receptor antagonist [123I]Iodobenzamide ([123I]IBZM) for quantification of viable graft volume and longitudinal grafts analysis. Methods: Six weeks after transplantation of 1000, 2000 or 3000 islets intramuscularly, rats received 50 MBq [123I]IBZM intravenously and one hour post injection SPECT images were acquired. Afterwards, animals used for ex vivo autoradiography were injected with [125I]IBZM, euthanized 1h post-injection, and the graft containing muscles were dissected for ex vivo SPECT, autoradiography and histological analysis. Viable graft volume was calculated histologically by multiplying insulin-positive area by interslice distance of the analyzed slides. For longitudinal graft analysis, rats were transplanted with 1500 islets and monitored for 10 weeks. Results: Six weeks after transplantation, a clear signal of all grafts was observed by SPECT. Moreover, SPECT signal correlated linearly with viable graft volume (Pearson r = 0,73). The SPECT signal in the calf muscle detected ex vivo correlated with the signal in the calf muscle in vivo. Furthermore, ex vivo autoradiography confirmed specific tracer accumulation and co-localization with the grafts location, as determined histologically. Longitudinal graft analysis showed a gradual increase in SPECT signal with a peak around five weeks after and signal stabilization afterwards. Conclusion: In conclusion, [123I]IBZM can successfully be applied for non-invasive quantitative and longitudinal graft monitoring in vivo. Especially in combination with other beta cell specific tracers, such as exendin, it might provide a strong tool to obtain detailed complementary information by non-invasive molecular imaging and to predict islet graft metabolic state and transplantation outcome.

OP203

Radioimmunoimaging of targeting CD133 antigen for colorectal cancer stem cells, a preliminary study

R. An, X. Jin, J. Lang, D. Weng, **X. Lan**; Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.

Objective: Cancer stem cells (CSC) provide a new approach for the diagnosis of malignant tumors. CD133 is the one of the most intensively studied biomarkers. The aim of this study was to target the colorectal CSC marker CD133 with 131I-labeled specific monoclonal antibody (AC133 mAb). Methods: The expression level of CD133 in three different colon cancer cells (HT29, HCT116 and DLD-1 cell) were detected by flow cytometry. 131I-AC133 mAb was prepared and identified. Cellular uptake studies were performed, and its relationship with the CD133 expression levels was analyzed. The tumor xenografts models were prepared for SPECT imaging and biodistribution experiments at different time points after 131I-AC133 mAb injected. Autoradiography and immunofluorescence studies were preformed to verify the CD133 expression in vivo. Results: The expression levels of CD133 molecules in HT29 and HCT116 cells were 91.33%±1.66% and 90.83%±2.47%, respectively, which were significantly higher than that in DLD-1 cells (3.87 ±0.57%). The radiochemical yield and radiochemical purity of 131I-AC133 mAb were 68.37% ± 2.45% and 91.18% ± 3.41% (n=3), respectively. Cellular uptakes of 131I-AC133 mAb in HT29 and HCT116 cells were 29.63% ± 3.92% and 33.99% ± 6.65% at 4 h, respectively, which showed significantly higher than that in DLD-1 cells (2.89% ± 0.90%, $P < 0.01$). After incubation with non-labeled AC133 mAb as a blocking group, the cellular uptakes were dramatically decreased to 3.22% ± 0.18% and 3.67% ± 0.56% in HT29 and HCT116 cells, respectively, which suggested specific binding. In vivo SPECT images, clear tumor signals were seen on the tumor sites of HT29 and HCT116 tumor-bearing mice at 7 d after injected 131I-AC133 mAb, and the tumor uptakes in biodistribution study were 5.49% ± 0.42% ID/g and 5.04% ± 0.05% ID/g (n=5), respectively, which were significantly higher than that in the DLD-1 tumor bearing mice (1.20±0.11% ID/g, $P < 0.05$). The ratios of tumor-to-muscle (T/B) at 7 d were 11.34±0.09 (HT29), 11.31±1.05 (HCT116) and 3.43±0.53(DLD-1), respectively.

The immunofluorescence and autoradiography studies showed the radioactivity distribution was consistent with the expression of the CD133 in vivo. Conclusions: 131I-AC133 mAb could target CD133 antigen in colorectal cancer cells specifically, and the uptakes of the tracers were correlate with the CD133 expression. These suggested that 131I-AC133 mAb was feasible as a radioimmunoimaging agent for targeting CD133-positive cancer stem cells. This work was supported by NSFC 81371599.

OP204

SPECT/CT Imaging of Programmed-Death Ligand 1 Expression of Tumors and Antigen-Presenting Cells

S. Heskamp[1], W. Hobo[1], J. D. M. Molkenboer-Kuenen[1], D. Olive[2], W. J. G. Oyen[1], H. Dolstra[1], O. C. Boerman[1]; [1]Radboud University Medical Center, Nijmegen, NETHERLANDS, [2]CRCM, Immunity and Cancer, Inserm, Marseille, FRANCE.

Introduction: Antibodies that block the interaction between the inhibitory signaling molecules programmed death-ligand 1 (PD-L1) and PD-1 have shown impressive anti-tumor activity. Patients with PD-L1 expressing tumors are most likely to respond to this type of treatment. Therefore, imaging of PD-L1 expression may aid in selecting patients for PD-1/PD-L1 targeting therapy. Previously we have shown the feasibility to image PD-L1 expressing human xenografts in mice. However, in patients, PD-L1 is also expressed on activated antigen presenting cells (APCs), such as dendritic cells and macrophages. This may hamper tumor visualization. The aim of our study is to determine what the effect of PD-L1 expressing APCs is on the tumor uptake of radiolabeled anti-PD-L1 antibodies. Material and methods: The anti-PD-L1 monoclonal antibody, PD-L1.3.1, was radiolabeled with Indium-111 (^{111}In). Two groups of immunodeficient NOD/SCID/IL2Rg(null) mice were irradiated (2.5 Gy whole body), followed by intrafemural transplantation of human CD34+ hematopoietic stem cells (HSCs). A control group was not irradiated nor transplanted. At day 54, mice were inoculated s.c. with MDA-MB-231 cells. Three weeks later, one HSC-transplanted group was injected i.p. with 0.6 mg/kg LPS in order to activate APCs and upregulate PD-L1 expression. One day later, all groups were injected i.v. with 13 MBq ^{111}In-PD-L1.3.1. Three days later, mice underwent SPECT/CT imaging and tissues were collected for ex vivo biodistribution. Results:SPECT/CT imaging clearly visualized MDA-MB-231 xenografts in all groups. In LPS-treated mice, ^{111}In-PD-L1.3.1 clearly visualized the activated cells in spleen and lymph nodes. Ex vivo biodistribution showed that tumor uptake was not significantly different between the groups (Control: 42.7 ± 8.1 %ID/g, HSC transplantation: 57.3 ± 12.0 %ID/g, HSC transplantation + LPS stimulation: 34.8 ± 18.2 %ID/g). Strikingly, spleen uptake was significantly increased in LPS-treated mice (Control: 16.7 ± 3.9 %ID/g, HSC transplantation: 25.9 ± 9.1 %ID/g, HSC transplantation + LPS stimulation: 85.1 ± 30.9 %ID/g, $p = 0.004$). Within the LPS-stimulated group, there was a significant correlation between spleen uptake and tumor uptake ($r=0.91$). Mice with the highest spleen uptake showed the lowest tumor uptake. Conclusion: This study showed the feasibility to image tumor PD-L1 expression, even in the presence of human PD-L1 expressing APCs. Upon LPS injection, APCs were activated and up-regulated PD-L1. This resulted in enhanced uptake of ^{111}In-PD-L1.3.1 in spleen and lymph nodes, as was visualized by SPECT/CT imaging. This did not hamper the visualization of PD-L1 expressing tumors.

OP205

Radiolabelled superagonist rhTSH analogues TR1401 and TR1402 for in vivo imaging of poorly differentiated thyroid cancer

F. Galli[1,2], I. Manni[3], G. Piaggio[3], L. Balogh[4], B. D. Weintraub[5], M. W. Skudlinski[5], R. A. J. O. Dierckx[2], A. Signore[1,2]; [1]Nuclear Medicine Unit, Department of Medical-Surgical Sciences and of Translational Medicine, Faculty of Medicine and Psychology, "Sapienza" University of Rome, Rome, ITALY, [2]Department of Nuclear Medicine and Molecular Imaging, University Medical Centre Groningen, University of Groningen, Groningen, NETHERLANDS, [3]Molecular Oncogenesis Laboratory, Experimental Oncology Department, Regina Elena National Cancer Institute, Rome, Italy, Rome, ITALY, [4]National "Frederic Joliot Curie" Research Institute for Radiobiology and Radiohygiene, Budapest, HUNGARY, [5]Trophogen Inc.,, Rockville, MD, UNITED STATES.

Introduction: Patients affected by poorly differentiated thyroid cancer (PDTC) may show a negative 131I scintigraphy because of the loss of the iodine symporter (NIS). However, expression of TSH receptor (TSHR) is usually preserved. Therefore, the aim of our study was to compare two new radiolabelled superagonist rhTSH analogues for imaging PDTC. Methods: Analogues (namely TR1401 and TR1402), with a TSHR binding affinity ten times higher than Thyrogen®, were radiolabelled with 99mTc using an indirect method via HYNIC conjugation. In vitro quality controls were performed to evaluate the stability of the labelling and the retained affinity for the receptor. These included SDS-PAGE, cysteine challenge and cell binding assay on TSHR positive cell lines lacking NIS. In vitro assays were also performed with radiolabelled human recombinant TSH (Thyrogen®) to compare affinity for the TSHR of each radiopharmaceutical. In vivo studies were

performed in 40 athymic nude CD-1 mice bearing either TSHR+ or TSHR- xenografts from human thyroid cancer cell lines. Furthermore, 4 dogs with spontaneous thyroid cancer were studied by 99mTc-TR1401 SPECT/CT, 99mTc-TR1402 SPECT/CT, 131I SPECT/CT and 18F-FDG PET/CT in different days within 2 weeks. Results: Suepragonist rhTSH TR1401 and TR1402 analogues were labelled with high labelling efficiency (>95%), high stability and retention of both biological activity and structural integrity. Analogues showed high affinity for the TSHR with dissociation constants (Kd) of 2.7 nM for 99mTc-TR1401, 0.5 nM for 99mTc-TR1402 and 8.4 nM for 99mTc-Thyrogen. In tumor targeting experiments, a focal uptake of radiolabelled analogues was observed in TSHR+ cells with a target-to-background ratio up to 3 at 3 h p.i., whereas no significant uptake was observed in mice bearing TSHR- cells. Similar observations were made in dogs with spontaneous intra-glandular papillary thyroid cancer, in which TSHR expression was confirmed by immunohistochemistry. Conclusions: We were able to efficiently radiolabel new superagonist rhTSH analogues with 99mTc with retention of in-vitro and in-vivo binding affinity with TSHR. 99mTc-TR1402 proved a high superiority than 99mTc-TR1401 and 99mTc-Thyrogen. This new radiopharmaceutical opens new perspectives for pre-surgical TSHR-based staging of thyroid cancer, for diagnosis of radioiodine negative cancer remnants, local relapses and/or distant metastases.

Investigation of kidney function with a dynamic FDG-PET/MR

B. K. Geist, A. Staudenherz; Medical University of Vienna, Vienna, AUSTRIA.

Aim: To study kidney function with FDG PET would be of clinical relevance for cancer patients undergoing staging before nephrotoxic chemotherapy will be applied. But investigation of kidney function with PET is a little explored field in nuclear medicine. The MR modality is suited for examine kidney, since the high-resolution morphological information of the MR allows a detailed discrimination of the FDG behavior in various regions in the organ. Our aim is to extract kidney function parameters (e.g. glomerular filtration rate, split kidney function, extraction function, etc.) from a single dynamic PET/MR scan. Methods: At the General Hospital in Vienna we started to acquire the time activity curves of the routine PET tracer F-18-FDG directly after injection separately for each kidney region, using MR images for kidney segmentation. From the temporal behavior of the tracer concentration in the different kidney regions as well as from the results from kinetic modeling, conclusions to the kidney function parameters are drawn. The obtained values are then compared to the results from MAG 3 renography and GFR-measurement. Results: So far the time activity curves from the FDG PET studies revealed a good correlation with the renal split function from MAG 3 renography. The preliminary results will be presented in detail. Conclusion: In order to facilitate the examination protocol for the determination of kidney functions, a PET/MR scan of the kidney is studied in comparison with routinely used kidney examinations in nuclear medicine and MR renography.

OP222
Wholebody Blood Pool in Bone Scintigraphy: Usefulness in the differential diagnosis of inflammatory arthritis - Preliminary Results

M. Casanova Martins, B. Patel, C. Humphreys, P. Ali; ABMU HB, Swansea, UNITED KINGDOM.

Introduction: To establish a differential diagnosis of inflammatory arthropathy (IA) it is important to assess the presence of hyperemia and increased relative tissue vascularity in bone scintigraphy. However, limiting early blood flow (BF) and blood pool (BP) imaging to a single symptomatic anatomic region might not entirely reveal the nature/extent of a multifocal systemic pathology. Instead, a global approach to the early imaging stages could be useful. This approach does not allow the

acquisition of the quick BF study to assess local hyperaemia yet allowing performing a wholebody blood pool (WB BP) study and therefore gathering systemic information on the tissue vascularity surrounding most joints. Aim: The aim of this work is to evaluate the usefulness of dual-phase wholebody skeletal scintigraphy in the assessment of IA. Materials and Methods: Between January 2014 and April 2015, 46 bone scans were performed for the assessment of IA. Patients underwent either triple-phase (n=40) or dual-phase bone scintigraphy (WB BP and delayed imaging) (n=6). Images and reports were retrospectively analysed. Results: In the triple-phase group, 60%(n=24) cases presented changes in all stages of the triple-phase scintigraphy, with accurate localization of active disease in the targeted joint. 100%(n=24) of these studies however, also presented increased uptake in other joints on delayed imaging. In 40%(n=16) studies there were no changes in the early imaging stages. Of these, only 25%(n=4) were completely normal in the delayed stage. In the remaining 75%(n=12) cases, the early imaging stages were normal, with marked increased uptake in other joints in the delayed stage, leading to inconclusive reports. In the dual-phase group, the report issued was conclusive in all cases. Of these, 67%(n=4) were positive, with matching changes in several joints in both stages of the study and 33%(n=2) had normal WB BP and increased multifocal uptake in the delayed WB scan. Discussion: The dual-phase WB protocol has increased the frequency of conclusive reports to 100% in the assessment of IA. Acquisition of early WB images increases the diagnostic accuracy whilst only adding 2-3 minutes to the study time. Hyperaemia is not assessed in dual-phase scintigraphy but this does not seem to affect the interpretation of these examinations. In addition, early WB imaging provides a systemic joint assessment allowing the evaluation of the extent of disease. Conclusion: Dual-phase wholebody skeletal scintigraphy is a simple but useful technique for the detection and characterization of widespread joint abnormalities and its routine use is recommended.

OP223

Comparison of Ga-68-DOTATATE PET/CT and In-111-octreotide SPECT/CT for the detection of neuroendocrine tumors

M. Kieft, E. A. Aalbersberg, M. P. M. Stokkel; NKI-AVL, Amsterdam, NETHERLANDS.

AIMIn our hospital, Ga-68-DOTATATE was implemented in Augustus 2011, and thereafter the number of Ga-68-DOTATATE PET/CTs is increasing rapidly at the expense of In-111-octreotide SPECT/CT. The aim of this study is to compare the detectability of neuroendocrine tumors (NET) between both techniques.MATERIALS & METHODSBetween August 2011 and February 2015 209 Ga-68-DOTATATE PET/CT scans were performed in 187 neuroendocrine tumor patients. In 111 cases the patients underwent an In-111-octreotide SPECT/CT and PET/CT; in 28 cases the scans took place within a maximum interval of 12 months.Based on the PET/CT reports, 12 cases showed one or more lesions, eight showed none and in eight cases the images were inconclusive. For the 12 cases with tumor lesions we scored the PET/CT, the SPECT/CT, and the planar images for total number of lesions and quantified the images. The lesions were divided in three categories: liver, skeletal, and other. The quantitative analysis of the PET/CT was based on SUVmax. On planar imaging and SPECT/CT lesions were scored visually (0= no uptake, 1= equivocal, 2≤ liver, 3> liver, 4= intense). Eight patients received somatostatin analogues between the scans. One lesion was resected and this lesion is removed from the analysis.RESULTSPET/CT depicted 149 lesions, SPECT/CT 41 lesions, and planar imaging 31 lesions. All lesions visible on SPECT/CT were found on PET/CT except for one. In the liver, 64 lesions were found with PET/CT, 19 with SPECT/CT and 16 with planar imaging. Of the 25 skeletal lesions on PET/CT, 3 were also seen on SPECT/CT and none on planar imaging. Sixty additional lesions were identified with PET/CT in other parts of the body, of which only 19 were visible on SPECT/CT and 15 on planar imaging. The discrepancy between PET/CT and SPECT/CT can be partially explained by the fact that whole-body SPECT/CT is not regularly performed, however in most cases Ga-68-DOTATATE PET/CT is more sensitive for NET then In-111-octreotide SPECT/CT.No correlation was found between SUVmax on PET/CT and visibility of the same lesion on SPECT/CT or the planar image.CONCLUSIONThese preliminary results show that Ga-68-DOTATE PET/CT has a higher detectability of lesions in comparison to In-111-octreotide imaging. Due to the ongoing application of Ga-68-DOTATATE more data will become available in the next months, which will also be analyzed. Based on these results, it can be concluded that In-111-octreotide scintigraphy alone is not standard clinical practice anymore.

OP224

Phase analysis using ECG-gated myocardial FDG PET in the rat in comparison with speckle tracking echocardiography

A. Mizutani[1], I. Matsunari[2], M. Kobayashi[3], K. Nishi[4], W. Fujita[5], S. G. Nekolla[6], K. Kawai[7], K. Fukuchi[1]; [1]Osaka University, Osaka, JAPAN, [2]Saitama Medical University Hospital, Saitama, JAPAN, [3]Kanazawa University, Kanazawa, JAPAN, [4]Nagasaki University, Nagasaki, JAPAN, [5]Kanazawa Medical University, Ishikawa, JAPAN, [6]Technical University Munich, Munich, JAPAN, [7]Osaka UniversityKanazawa University, Kanazawa, JAPAN.

Aim: Clinical studies have shown that phase analysis using ECG-gated myocardial SPECT/PET is useful for assessing left ventricular dyssynchrony. However, its feasibility has not yet been validated in small animals such as rats, where small heart size and high heart rate pose a technical challenge. The aim of this study was to assess the feasibility of phase analysis using ECG-gated myocardial FDG PET in rats with myocardial infarct in comparison with speckle tracking echocardiography as a reference standard for dyssynchrony. Methods: Twenty-nine Wister rats with myocardial infarct underwent ECG-gated FDG PET in list-mode for 20 minutes using a dedicated small animal PET scanner (Triumph II/LabPET8, TriFoil Imaging). Image reconstruction was performed using ordered-subset expectation maximization (OSEM) in 16 frames per cardiac cycle. All the rats also underwent speckle tracking echocardiography using Vivid7 (GE Healthcare) with a small and high-frequency (~14 MHz) linear transducer (i13L, GE Healthcare). For PET, standard deviation of time to peak thickening (PET_SD) was calculated as an index of dyssynchrony using AHA 17 segment model. For speckle tracking echocardiography, standard deviation of time to peak radial strain on a mid-ventricular short-axial image (echo_SD) was obtained as an echocardiographic index of dyssynchrony. Results: PET_SD measured by ECG-gated PET showed a significant positive correlation with echo_SD ($R=0.597$, $p<0.001$). In addition, PET_SD showed significant correlations with measures of disease severity such as left ventricular ejection fraction ($R=-0.575$, $p<0.001$) and infract size ($R=0.614$, $p<0.001$). Conclusion: Our results indicate that phase analysis using ECG-gated myocardial FDG PET is feasible in the rat model of myocardial infarct, and thus may provide a measure of left ventricular dyssynchrony.

OP225

Eye Spy: An Investigation into Tc-99m Pertechnetate Lacrimal Scitigraphy for Protocol Optimization

E. Souza, **V. Janse van Rensburg**, P. Sandhu, L. Perry, H. Tam, Z. Win; Imperial College Healthcare NHS Trust, London, UNITED KINGDOM.

Aim: To assess the change in diagnosis between three different lengths of acquisition (0-15mins, 0-23mins, 0-31mins) and post-rinse static to determine if a shorter acquisition will yield the same clinical result for lacrimal scintigraphy studies using Tc-99m pertechnetate. Our local protocol uses a 31minute dynamic (eighteen 10-seconds frames, then 60-second frames), followed by a 60second, post rinse static view. The aim of this study was to evaluate the clinical utility of extra data collected after the initial 15minutes dynamic acquisition. Materials and Methods: Data was retrospectively collected from 40 patients referred to our department for lacrimal scintigraphy, over a period of 6 months. The right side and left side of each patient were considered as separate systems, thus a total of 80 lacrimal systems were evaluated. Anonymised printscreens were produced showing data acquired 0-15mins, 0-23mins, 0-31mins post administration and the post-rinse static. Two radiologists reviewed the images recording their diagnosis based on 0-15mins, 0-23mins and 0-31mins of data post administration. The diagnosis reached when the post rinse image was reviewed was also recorded. Diagnosis was categorised as no obstruction, partial obstruction or total obstruction, pre and post sac. We calculated the percentage of lacrimal systems where there was a change in diagnosis between the 0-15mins vs 0-23mins and 0-23mins vs 0-31mins datasets. We also calculated the change between each separate dataset and the post-rinse diagnosis eg 0-15mins vs post-rinse. Results: The percentage of lacrimal systems where there was a change in diagnosis changed was 14.4% between the 0-15mins vs 0-23mins and 7.5% between the 0-23mins vs 0-31mins. When the diagnosis reached from the post-rinse static image was compared to the diagnosis reached from the other time-frames: 31.3% was changed vs 0-15mins; 21.9% was changed vs 0-23mins diagnosis; 16.3% was changed vs 0-31mins diagnosis. Conclusion: This study demonstrates that although there is still a substantial amount of information after a 15minute dynamic phase, as the duration of the initial dynamic phase of lacrimal scintigraphy increases the impact on diagnosis is reduced. However we found there was a significant change in diagnosis after the post-rinse images. Therefore we would suggest that a shorter acquisition protocol could be adopted clinically as long as the post-rinse image is included. We suggest a shorter dynamic acquisition of 23minutes followed by a post-rinse image would increase patient throughput and comfort whilst maintaining diagnostic accuracy.

OP226

Radionuclide therapy of metastatic melanoma with benzamide derivate I-131-BA100 after patient stratification with F-18-DOPA

F. O. Spohn, K. Kunze, F. Giesel, W. Mier, U. Haberkorn, C. Kratochwil; Heidelberg University Hospital, Heidelberg, GERMANY.

Aim:Benzamide derivates have been shown to selectively accumulate in melanotic melanoma. Some patients with metastatic melanoma show therapeutically promising accumulation of the benzamide derivate I-131-BA100.L-DOPA is a precursor to the biological pigment melanin.We evaluated if it's possible to select which patient could benefit from a radioligand therapy with I-131-BA100 using F-18-DOPA for prediagnostic.Methods:15 patients with metastatic melanoma were examined. In line with the propagation diagnostic and

staging a F-18-FDG PET/CT was acquired.With regard to a radionuclide therapy both I-131-BA100 whole body scan and PET/CT with the melanin precursor F-18-DOPA were done at intervals of few days.48 hours after intravenous injection of 230 +/- 35 MBq I-131-BA100 planar whole body scans and tomographic images in SPECT technique were acquired.In the best case the F-18-DOPA examination was done on the very same day of benzamide imaging. After intravenous injection of 215 +/- 55 MBq F-18-DOPA 15 minutes p.i. an emission scan of the trunk and a low-dose CT for attenuation correction was processed.Results:Benzamide- and DOPA-examination showed no pathological retention in known multiple metastases in 4 patients. 10 patients showed congruent findings with both tracers. On the contrary there was found a discrepant case. This patient had moderate to intensive DOPA-positive lesions which showed no retention with the benzamide-derivate.Conclusion:The correlation of F-18-DOPA- and I-131-BA100-uptake is sufficiently enough to preselect patients who could benefit from this type of therapy. Because of the individual case of missing correlation between benzamide- and DOPA-uptake diagnostic imaging with I-131-BA100 is still advisable.

OP227

Impact of syringe residual activity in SUV measurement

P. Felício[1], J. Hunter[2], N. G. Dowell[2], T. Vaz[1], F. Lucena[1]; [1]Lisbon School of Health Technology, Lisbon, PORTUGAL, [2]Clinical Imaging Sciences Centre, Brighton and Sussex Medical School, University of Sussex, Brighton, UNITED KINGDOM.

The use of the semi-quantification standard uptake value (SUV) in PET/CT image has an important role in the evaluation of individual response to therapy however many factors may interfere with the calculation of SUV. One factor is the residual activity in the syringe after injection. The aim of this research is to assess the influence of the syringe residual activity in the SUV, in PET/CT images with ^{18}F-FDG. Forty-eight patients with clinical indication for performing PET/CT with ^{18}F-FDG were included. Inclusion criteria were: avid ^{18}F-FDG tumour uptake in the PET/CT images and blood glucose level between 4 and 8 mmol/L. Images were acquired 1 hour after the radiopharmaceutical injection (400 MBq) according to departmental procedure. Reconstruction and processing of the images were performed with ordered subset expectation maximization (OSEM) algorithm (4 iterations; 8 subsets; 5 mm Gaussian filter), 168x168 image matrix; zoom 1; voxel size 5 mm^3. A dose modulated CT scan was acquired prior to the PET scan for attenuation correction (120 KV; 50 mAs (ref); 5 mm slice thickness). Maximum SUV (SUV_{max}) based on patient weight was obtained, with (SUV_{max}-C) and without correction (SUV_{max}-NC) for the injected activity, keeping the same procedure (ROI area, slice and lesion). Descriptive and inferential statistics (t-test for paired-samples and person-correlation) were applied (IBM SPSS software, version 22). Significance was considered for p-value<0.05. After the data collecting, mean values were obtained: ^{18}F-FDG activity (393±21 MBq), syringe residual activity (3.38±2.43 MBq), ROI area (1.69±0.65 pixels), SUV_{max}-C (12.33±6.37), SUV_{max}-NC (11.95±6.18). As it was expected a strong linear positive correlation (r=0.99, p-value=0.00) was found between the two SUV_{max}. However, the comparison of means showed statistically significant differences (p-value=0.00), associated with an increase of SUV_{max} after correction. These results are in agreement with the SUV empirical formula, which takes into account the activity concentration in the ROI and the injected activity. This way, the corrected activity will produce an increase in the SUV_{max} obtained. No correlation was shown between SUV_{max}-NC and SUV_{max}-C, with regard to the injected activity, the syringe residual activity or patient weight. The correction for syringe residual activity increases the SUV_{max} and further research should be performed in order to identify the clinical impact of this difference. It is recommended that the same method for SUV_{max} measurement is applied, especially in the evaluation of individual response to therapy.

OP228

Protocol Optimisation of [^{68}Ga]-PSMA PET/CT Imaging on a High Sensitivity Time-of-Flight Pet Scanner

E. A. Bailey, E. Hsiao, G. Schembri; Royal North Shore Hospital, Sydney, AUSTRALIA.

AIM: The use of [^{68}Ga]-PSMA PET/CT in the staging and response to therapy of patients with prostate cancer is increasing. There are limited guidelines suggesting the ideal parameters to ensure high image quality using a Time of Flight (ToF) PET/CT system. We used external triggered gating to investigate the optimal scanning parameters (dose injected, time per bed position) for whole body PSMA PET scanning on a Siemens Biograph mCT with extended axial field of view (FoV), time-of-flight scanner with resolution recovery (HD).METHODS: Patients referred for a PSMA PET scan with a rising PSA were injected with 150MBq of [^{68}Ga]-PSMA (HBED). An externally triggered gated (ETG) WB PET scans were acquired at 60 minutes on a ToF PET/CT (Siemens Biograph mCT64x64). Data were reframed into 30 sec time bins (6 gates) using ToF 3D-OSEM with CT-based AC, SC and PSF recovery and then combined using in-house software to give different total acquisition times (30 secs, 60secs, *etc* up to 180 secs). ROIs are defined over areas of assumed homogeneity (*e.g.*, liver and salivary glands), lesions, bladder and blood pool across all reformatted studies. Image

coefficient of variation (CoV%), SUV_{max} and visual assessment were used to quantify the relationship between dose injected and time per bed position.RESULTS: A total of 6 studies were included for analysis with an average injected dose of 141MBq (125-165MBq), weight 81kg (71-88kg) and PSA range 3 to 56ng/mL. Based on a PSMA injected dose of 141MBq, the scanning time per bed position appears to plateau based on CoV% in liver, nodes and salivary glands at around 120 secs per frame. The SUV_{max} was reproducible from 60secs to 180secs acquisition time with a maximum deviation in the shortest time frames of <15%.CONCLUSION: The use of ETG acquired data to assess varying parameters such as different acquisition times and injected doses allows the assessment of the impact on image quality between injected dose and scanning duration. In this analysis, the image quality and reliability of quantitative measures such as SUV_{max} appears to be achieved at 120secs per bed position with an injected dose administered of 141MBq. This approach is now being used to assess optimal parameters for PSMA PET delayed imaging acquired between 120 and 180 minutes post injection.

OP229
SPECT/CT for Anatomical Mapping of Lymphatic Drainage in Vulvar Cancer: Possible Implications for the Extent of Inguinal Lymph Node Dissection

A. Collarino[1,2], M. L. Donswijk[2], W. J. van Driel[3], M. P. Stokkel[2], R. A. Valdés Olmos[2,4]; [1]Institute of Nuclear Medicine, Università Cattolica del Sacro Cuore, Roma, ITALY, [2]Department of Nuclear Medicine, The Netherlands Cancer Institute – Antoni van Leeuwenhoek Hospital, Amsterdam, NETHERLANDS, [3]Department of Gynaecological Oncology, The Netherlands Cancer Institute – Antoni van Leeuwenhoek Hospital, Amsterdam, NETHERLANDS, [4]Interventional Molecular Imaging Laboratory and Nuclear Medicine Section, Department of Radiology, Leiden University Medical Center, Leiden, NETHERLANDS.

Aim: to assess the lymphatic drainage pattern using SPECT/CT in clinically node-negative (cN0) patients with vulvar cancer, and to evaluate the possible implications for the extent of inguinal lymph node dissection.Material and Methods: Lymphoscintigraphy and SPECT/CT were performed in 83 patients (mean age 67.8, range 25-93y) vulvar cancer patients scheduled for sentinel node (SN) biopsy after four peritumoral injections of 99mTc-nanocolloid. Using SPECT/CT SN and higher-echelon nodes were identified and were anatomically localized in the groin according to Daseler's five zones: four zones obtained by drawing two perpendicular lines over the saphenofemoral junction and one zone directly overlying this junction. Lymph nodes into the pelvis were classified into three zones: external iliac/obturator, the common iliac and the para-aortic zones.Results: A total of 217 SNs and 202 higher-echelon nodes were localized using SPECT/CT. All SNs were located in the groin and were classified in one of the five zones according to Daseler: 149 (69%) in the medial superior region, 31 (14%) in the medial inferior region, 22 (10%) in the central region, 14 (6.5%) in the lateral superior region and only 1 (0.5%) in the lateral inferior region. The higher-echelon nodes were located both in the groin (15%) and in the pelvic region (85%).Conclusion: In cN0 vulvar cancer patients scheduled for the SN procedure, lymphatic drainage occurs predominantly to the medial regions of the groin. Drainage to the lateral inferior region of the groin is only incidental, and in SN positive patients this zone might be spared for subsequent extended lymph node dissection; this may lead to a decrease of the morbidity associated with this procedure. SPECT/CT is able to personalize lymphatic mapping, providing detailed information about the number and anatomical location of SNs for adequate surgical planning in the groin.

OP230
3D freehand-SPECT navigation for intraoperative radioactive seed localisation using single or multiple 125I seeds in breast-conserving cancer surgery

B. Pouw, L. J. de Wit-van der Veen, F. van Duijnhoven, E. J. T. Rutgers, R. A. Valdés Olmos, M. P. M. Stokkel, M. T. F. D. Vrancken Peeters; Netherlands Cancer Institute, Amsterdam, NETHERLANDS.

Background: The use of mammographic screening has led to the identification of more women with non-palpable breast cancer. For subsequent treatment adequate localisation techniques are required for radical excisions. For radioactive seed localisation (RSL) a radioactive Iodine-125 seed (125I-seed) is implanted in the centre of the tumour and intraoperatively localised using a gamma probe. In case of extensive ductal carcinoma in situ (DCIS) or multifocal carcinoma, multiple 125I-seeds can be used to delineate the borders of the involved area. For localisation control of the seed, preoperative imaging is not performed in the surgical position and therefore the exact 125I-seed depth remains unknown during surgery. For this purpose, we evaluated freehand-SPECT (fh-SPECT), which facilitates 3D navigation towards the 125I-seed. Methods: Fourteen female patients (Mean age 56 years) with 21 implanted 125I-seeds scheduled for RSL were included. Eleven patients had 1 125I-seed implanted in the primary lesion, 2

patients 2, 1 patient 3. In 3 patients, an additional 125I-seed was implanted as a marker for an up-front systemically treated tumour-positive axillary lymph node. Fh-SPECT localised 125I-seeds by measuring gamma counts from different directions all registered by an optical tracking system. A reconstruction and visualisation algorithm enabled 3D navigation towards the 125I-seeds. Surgeons estimated the depth of 125I-seeds after excision and compared this with the depth indicated by fh-SPECT. Results: Fh-SPECT visualised all 125I-seeds in the primary tumours and provided pre-incision depth information. The deviation between the fh-SPECT depth and the surgical depth estimation was 2.7 mm (SD 2.1mm, Range 0-7mm). 3D fh-SPECT was especially useful identifying multiple implanted 125I-seeds where the conventional gamma-probe has more difficulty to discriminate 125I-seeds by transcutaneous measurements. In two patients the excision was irradical and tumour was detected at the resection border; for 1 patient a DCIS component was detected at the resection margin and another patient had invasive ductal carcinoma in the resection border. In one patient a diagnostic excision of three lesions was performed of which one contained tubular carcinoma. Conclusion: Fh-SPECT with 3D navigation is feasible in RSL based on single or multiple implanted 125I-seeds. The modality is able to provide real-time 3D information about the depth and location of the 125I-seeds, contributing to adequate excision of non-palpable breast cancer. 3D navigation may become important in breast-preserving cancer surgery.

OP231

Intraoperative evaluation of a true hybrid modality for combined radio- and fluorescence guided sentinel node biopsy

N. S. van den Berg[1,2], H. Simon[3], G. H. KleinJan[1,2], J. Chambron[3], B. M. Tijink[2], S. Horenblas[2], F. W. B. van Leeuwen[1,2]; [1]LUMC, Leiden, NETHERLANDS, [2]AVL-NKI, Amsterdam, NETHERLANDS, [3]Eurorad, Strassbourg, FRANCE.

Introduction:The clinical implementation the hybrid tracer ICG-99mTc-nanocolloid, that is composed of a near-infrared fluorescence component (ICG; indocyanine green) and a radioactive component (99mTc-nanocolloid), has stimulated the generation of sophisticated imaging modalities that allow consecutive detection of the two signatures. In the current study, we report on the first-in-human use of a true hybrid opto-nuclear modality for image-guided surgery.Materials and Methods:Nine patients scheduled for sentinel node biopsy of penile (n=7) or head and neck cancer (n=2) were included after obtaining written informed consent. The number and location of the sentinel node(s) were determined after hybrid tracer injection and subsequently lymphoscintigraphy (15min and 2hours post-injection) and SPECT-CT imaging (2.5hours post-injection). Intraoperatively, sentinel nodes were pursued using the hybrid opto-nuclear modality (prototype; Eurorad, Strassbourg, France). After initial localization of the gamma signal, the probe was switched to the fluorescence mode. Fluorescence tracing was performed under ambient light condition. First in the high sensitivity mode (0.9V) first, and after confirming the location of the node the settings were switched to a low sensitivity mode (0.7V). Post-excision, the measurements were repeated on the surgical specimens. 5-Second count rates were noted for both gamma and fluorescence tracing. Obtained fluorescence tracing results were compared to the results obtained with the conventional fluorescence camera (PDE; Hamamatsu Photonics, Hamamatsu, Japan).Results:In the nine patients included in this trial, intraoperatively 20 sentinel nodes were pursued. All SNs could be gamma traced. In the high sensitivity mode, all sentinel nodes were detected via fluorescence tracing (20/20). In the low sensitivity mode, however, only 7/20 nodes could be traced (35%). Presence of the fluorescence signal in the node was confirmed in all cases using the fluorescence camera. Surgeons that were used to gamma tracing considered fluorescence tracing with the opto/nuclear-probe technology intuitive and the ability to trace this signature in ambient light was considered valuable for surgical logistics.Discussion:The hybrid surgical guidance modality that allows for combined gamma and fluorescence tracing proved to be feasible and was considered a valuable addition during sentinel node biopsy procedures that use the hybrid tracer ICG-99mTc-nanocolloid.

OP232

Role of Robotic assisted PET-CT guided biopsy in 18F-FDG/Ga68 DOTANOC avid suspicious lesions

S. Gambhir, A. Prashanth, S. Barai, H. Lal, A. Nath, G. Sankar, N. Kumar, M. Ravina; Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, Uttar Pradesh, INDIA.

Aim: To evaluate the role Robotic guided PET-CT biopsy in terms of histopathological yield and complication rate. Introduction: CT guided biopsy of lesions with high necrotic content is unfruitful in most circumstances. So PET-CT guided biopsy will alleviate the flaws of both CT guided biopsy and PET-CT as standalone modalities. Robotic systems can enhance surgical and interventional procedures through improved precision, stability, and dexterity. The high precision of registration, planning, and movement of the robotic arm enables an effective biopsy in all cases, with a high accuracy for even relatively small targets. Materials and methods: 20 patients were referred for PET-CT guided biopsy in our center for the following indications, Unknown primary with likely

primary detected from PET-CT, suspicious lesions identified from PET-CT in a known primary disease and FNAC or CT guided biopsy negative lesions which are high index of suspicion for malignancy. Procedure was done on an outpatient basis with written informed consent after appropriate investigations. PET CT along with contrast was done in order to locate the larger vascular structures near the lesion. Biopsy procedure was done on a separate day planned using the already acquired PET-CT images. 3 cases which were excluded due to the following reasons lesion resolved completely on check scan, severe dyspnoea which prevented stable positioning of the patient, procedure abandoned because of needle in dangerously close proximity to aorta. Results: Tissue was adequate and histo-pathological diagnosis was achieved in all patients except one in whom a repeat procedure yielded positive results. The locations of lesion were thoracic in 88%, spine in 6% and pelvis in the rest 6% of patients. Out of the 17 lesions biopsied 11% (2 lesions) were benign and 89% (15 lesions) turned out to be malignant. Tissue yield from the procedure was 100%. The only complication (1 out of 17 patients - 6%) which arose was self limiting pneumo-thorax. Conclusion: In sharp contrast to the CT guided manual procedure which requires multiple check CT scans robotic procedures inherently need lesser manipulation by user. Robotic assisted PET-CT procedures have lesser complications better histo-pathological yield. It also results in lesser radiation dose to the patient and short learning curve.

OP233
FDG PET/CT Guided Biopsy

C. NANNI[1], A. CAPPELLI[1], T. BALBI[1], F. MANGIACOTTI[1], A. GASBARRINI[2], T. GRAZIANI[1], I. SANDLER[1], R. GOLFIERI[1], S. FANTI[1]; [1]AOU S.ORSOLA-MALPIGHI, BOLOGNA, ITALY, [2]IOR, BOLOGNA, ITALY.

Biopsy of suspect tissues is required to reach a definitive diagnosis. Open incisional biopsy (OIB) is traditionally the method of choice, providing an accuracy of approximately 100%. OIB is very expensive and is associated with several drawbacks (morbidity, surgical complications, tumor contamination of surrounding tissues). The development of imaging-guided biopsies (ultrasound, computed tomography) has almost overcome these disadvantages. However, in recent literature a variable amount of non-diagnostic procedures is reported, leading to an accuracy ranging between 70%-90%. FDG PET/CT is a functional imaging technique highlighting areas of active malignancy/infection with a very high sensitivity in comparison to conventional imaging. It detects abnormal signals even before cancer-related morphological changes occur, and can accurately discriminate between fibrous residual tissue after therapy and disease persistence or relapse. It can potentially be used to drive the biopsy to the most active lymph node or to the most active area within a suspect mass. Aim of this study is to preliminary assess FDG PET/CT guided biopsy feasibility and accuracy in the diagnosis of malignancy/infection.So far 7 patients with unclear hypermetabolic findings were enrolled (5F,2M, mean age 50). 5/7 had a suspect malignancy relapse (3 anorectal, 1 ovarian, 1 NHL) and 2/7 did not have a significant clinical history. 4/7 had a previous non diagnostic CT-guided biopsy. They underwent a FDG PET/CT guided biopsy performed by experienced personnel (interventional radiologist, nuclear medicine doctor, orthopedic). 5/7 pts underwent also contrast media injection to depict vessels surrounding the lesion used to help in drawing the most appropriate needle route. The needle was tracked by driving its progression into the area with the highest SUVmax through repeated PET/CT acquisition (1bed/position; acquisition time 1 min). On average, the procedure lasted approximately 1h per patient. The sample was laid down on adhesive glass slide to obtain cytological extemporaneous exam to test its adequacy and, in some cases, for an immediate diagnosis. 6/7 pts had a definitive pathological diagnosis after PET/CT biopsy (1TBC, 1sacral chordoma, 2 rectal ca relapse, 1 serous papillary ovarian ca, 1 intermediate lymphoma) while in 1 pt histopathology demonstrated post RT scar tissue. This pt is currently in follow-up. No pts had complications. These preliminary results prove that FDG PET/CT guided biopsy is feasible in the clinical practice. Furthermore it positively impacted on the time to treatment onset in those pts who presented with a previous non diagnostic biopsy.

OP234
MRI based identification of lymph nodes and nerves, the next step in sentinel node procedures for head and neck cancer?

T. Buckle[1], B. M. Verbist[1], G. H. KleinJan[1], M. de Ruiter[1], M. A. van Buchem[1], A. J. Balm[2], F. W. B. van Leeuwen[1]; [1]LUMC, Leiden, NETHERLANDS, [2]NKI-AvL, Amsterdam, NETHERLANDS.

Background: Sentinel node (SN) procedures in the head-and-neck area are challenging due to the many critical anatomical structures located in the five dissection regions (Level I-V). Preoperative SN identification, based on SPECT/CT, and radioguided dissections are limited in their ability to identify clustered SNs. Nor do these imaging technologies provide insight in the location of peripheral nerves adjacent to the SNs. In search of methods that allow more detailed lymph node (LN) identification and visualization of peripheral nerves, a new MRI-based imaging technology was evaluated. The locations of the visualized LNs were compared to the SN

visualization-rate in a historic cohort of patients. Methods and Patients: Retrospective analysis of a database containing pre-operative imaging results (SPECT/CT) and pathology reports from 100 head-and-neck melanoma and 40 oral cavity cancer patients was used to evaluate the incidence of SN visualization and occurrence of metastasis per dissection level. Nerve imaging was performed on a Philips 3T Ingenia MRI scanner in fifteen healthy volunteers using a D-prep MRN sequence (scanning-time: 2-5 minutes) and a standard head coil. Anatomical reference images were acquired using a standard T1-3D TSE sequence. An Overlay of both MR images was used to place the LNs and nerves in their anatomical context. Results: Retrospective assessment of SPECT/CT-based preoperative visualization of SNs revealed that 61% of were visualized in levels I-III (61%), and herein 54% contained micrometastases. With D-prep MRN LNs could be detected with a significant improvement in the level of detail as compared to low-dose CT. The highest density of LNs was seen in dissection level I - III and discrimination could be made between single nodes and clusters of 3-5 nodes. Next to allowing the identification of LNs, this MRI technology also improved the insight in the location of the facial nerve including its mandibular, zygomatic and cervical branches (diameter: 0.19 ± 0.04, 0.17 ± 0.03 and 0.19 ± 0.03 mm respectively). Variation in the course of the visualized nerves, in relation to the submandibular salivary gland, as well as variation in the location, amount (27 ± 10 LNs per subject) and size (range 21-1085 mm3) of the LNs was seen between volunteers. Conclusion: D-prep MRN enabled detailed visualization of single LNs located in clusters and facial nerve branches, which contributes to improved pre-operative assessment of sentinel node procedures.

The potential of F-18 Fluoride PET as a surrogate for Radium-223 chloride lesion dosimetry in hormone refractory prostate cancer patients

I. Murray, S. J. Chittenden, C. C. Parker, G. Flux; Royal Marsden NHS Foundation Trust, Sutton, UNITED KINGDOM.

Aim: The aim of this investigation was to assess the response of castration-refractory prostate cancer bone metastases to 223Ra-chloride treatment using sequential 18F-Fluoride PET imaging. Additionally we hypothesised that since 18F-Fluoride and 223Ra share a common biological target, a single 18F-Fluoride scan at baseline could serve as a surrogate for 223Ra-chloride dosimetry. Methods: Five patients received two intravenous injections of 223Ra chloride, 6 weeks apart, at 100 kBq per kg whole-body weight. The pharmacokinetics and biodistribution of 223Ra-chloride as a function of time were determined. In addition PET/CT imaging using 18F-Fluoride was carried out immediately prior to treatment, prior to the second treatment at week 6, and subsequently at 12 weeks after baseline. Changes in both the SUVpeak and the percentage injected activity per kilogram of each lesion were measured and plotted against baseline 18F-Fluoride uptake on a lesion by lesion basis. Results: A total of 33 lesions were identified. Relatively small changes were observed in the uptake of lesions between baseline and 6 weeks. More significant changes were observed between baseline and 12 weeks. There was a clear correlation between baseline uptake of 18F-Fluoride and the subsequent decrease in 18F-Fluoride uptake at 12 weeks (r2 = 0.88). The hypothesis that 18F-Fluoride uptake could predict the effect of 223Ra-chloride treatment was further supported by the demonstration of a correlation (r2 = 0.79) between 223Ra and 18F-Fluoride uptake in metastatic bone lesions as well as the observation that the effective half-life of 223Ra-chloride in metastatic lesions was close to the physical half-life. Conclusion: Analysis of this small group of patients suggest that uptake of 18F-Fluoride has the potential to predict subsequent response to 223Ra-cloride therapy and serve as a surrogate measure of tumour dose.

OP236

Feasibility of 223Ra quantitative imaging for lesion dosimetry

G. A. Follacchio[1], V. Frantellizzi[1], R. Pellegrini[1], R. Pani[1], M. Pacilio[2], B. Cassano[2], M. Liberatore[1], F. Monteleone[1], T. Garkavaya[1], G. Ventroni[2], L. Mango[2], G. De Vincentis[1]; [1]Policlinico Umberto I - Sapienza University, Rome, ITALY, [2]A.O. San Camillo-Forlanini, Rome, ITALY.

223Ra-chloride is a novel bone-targeting radiopharmaceutical effective on bone pain in patients with metastatic castration-resistant prostate cancer. In 223Ra complex decay spectrum, α particles account for nearly 95% of emissions while photons represent less than 2% of total decay energy. Aim of this study was to evaluate feasibility of an imaging procedure based on 223Ra γ-emitting component in order to acquire significant data for personalized dosimetric evaluation. Nine male patients receiving 223Ra-chloride treatment (50 kBq/kg every 4 weeks for 6 injections) were enrolled. On the basis of 99mTc-MDP bone scan, we selected a single area of interest (thorax or pelvis) characterized by relevant bone metastasis. Gamma-camera calibration measurements with a source of 223Ra were carried out including sensitivity test and transmission curves. For each patient we performed serial planar static images of the chosen district on the 3rd-7th-14th-21st day after

first 223Ra injection (double-peak acquisitions with energy window centred at 82 and 158 keV, each 20% wide, MEGP collimator, 256x256 matrix, acquisition time 40'). In 3 patients we could perform early acquisitions at 4 and 24 h. For most of the patients, transmissive images were also acquired. Bone lesions were manually delineated on 99mTc-MDP bone scan, then ROIs were superimposed to 223Ra serial images after spatial co-registration with bone scan performed by a MATLAB tool. Activity quantification was performed correcting by attenuation, scatter and partial background subtraction. Absorbed dose to lesions was assessed by MIRD approach deriving S-values from OLINDA/EXM tabulations, estimating lesion volume by CT contouring. 99mTc percent uptake was evaluated on bone scan images. Over nine patients, twenty-four lesions were delineated at bone scan. Twelve lesions showed a wash-in phase, so biokinetics was assumed bi-exponential; mono-exponential biokinetics was assumed for remaining lesions. 223Ra effective half-life showed a median value of 7.8 days. Median absorbed dose to lesion for a single injection resulted 0.6 Gy (range 0.2-1.9 Gy); considering Relative Biological Effectiveness for α particles (RBE=5), DRBE /Aadm to lesions ranged from 340 to 2450 mGy/MBq. 99mTc and 223Ra percent uptake resulted significantly related on linear regression analysis. Our experience confirmed feasibility of quantitative imaging in patients treated with 223Ra-chloride. Collected data were useful to perform biokinetics studies and bone lesion dosimetry. Optimal timing for serial acquisitions resulted at 4, 24, 48 and 168 h. Absorbed dose to lesions was remarkable compared to β-emitting bone-seeking radiopharmaceuticals. Significant correlation between 99mTc-MDP and 223Ra percent uptake could allow dosimetry-based treatment.

OP237

A Monte Carlo study of small-scale dosimetry in capillary vessels during internal radionuclide therapies with 223Ra, 111In, 131I and 177Lu

S. Leotta[1], **E. Amato**[1], A. Italiano[2], L. Auditore[1], R. Gentile[1], S. Baldari[1]; [1]University of Messina, MESSINA, ITALY, [2]Istituto Nazionale di Fisica Nucleare, MESSINA, ITALY.

This study was aimed to evaluate the combined effects of radiopharmaceutical diffusion and range of the emitted radiation in a model of tumour capillary vessels. We developed a computational model representing a blood capillary vessel surrounded by solid tumour tisssue, and we simulated the transport of radiation emitted by by 223Ra, 111In, 131I and 177Lu nuclides using two different Monte Carlo codes: Geant4 and MCNPX. In particular, we simulated a cylindrical vessel having 10 um of inner radius and 10 um of thickness filled by blood and surrounded by cylindrical layers of soft tissue, 10 um thick each. For each nuclide, several models of radiopharmaceutical outflow through the capillary vessel were considered: in blood only, representative of radio-embolization procedures, in capillary cells, representative of an anti-angiogenic radiopharmaceutical accumulating in them, and several models of extra-vascular dispersion. Radial dose profiles around the capillary vessel were obtained and compared between codes and between the physics models available. The results for beta and Auger emitters demonstrate that the photon dose is at least four orders of magnitude lower with respect to the one deposited by electrons. For which concerns 223Ra, the beta emissions of the daughters give a contribution three orders of magnitude lower with respect to the alpha particles, even if with a much longer range. For each nuclide and for every diffusion model, the Endothelial Cell Mean Dose (ECMD) and the Tumour Edge Mean Dose (TEMD) per unit cumulated activity were computed and represented in tabular form, together with the initial radioactivity (IR) necessary to deposit 100 Gy of dose at the edge of the viable tumour. Such results may help to characterize the dose inhomogeneities in solid tumour therapies with radiopharmaceuticals, taking into accunt the interplay between drug diffusion from vasculature and range of ionizing radiations.

OP238

Factors Affecting RADIUM-223 Therapy

E. Etchebehere, J. Araujo, D. Milton, N. Swanston, H. Macapinlac, E. Rohren; The University of Texas MD Anderson Cancer Center, Houston, TX, UNITED STATES.

AIM: The purpose of this study was to evaluate the factors that may affect Radium-223 therapy (Ra-223). MATERIALS AND METHODS: We retrospectively reviewed 110 histologically confirmed hormone-refractory prostate cancer patients (42-88 y old; mean 69yrs.) with bone metastases, with or without visceral and nodal metastases. End points were overall survival (OS), progression-free survival (PFS), time to progression (TTP), bone event-free survival (BeFS), and bone marrow failure (BMF). The following parameters were evaluated prior to the 1st Ra-223 cycle: hemoglobin ($Hb_{Initial}$) levels (<10 vs >10g/dl), PSA levels ($PSA_{Initial}$<10 vs >10ng/ml), ALP levels ($ALP_{Initial}$<147 vs >147IU/L), ECOG status ($ECOG_{Initial}$), pain score ($pain_{Initial}$), use of chemotherapy ($Chemo_{Prior}$) and external beam radiation therapy ($EBRT_{Prior}$). Additionally, the total number of radium cycles (Ra_{Tot}) were evaluated. During/after Ra-223 the following parameters were evaluated: PSA doubling time (PSA_{Dt}), use of chemotherapy ($Chemo_{During/After}$), $EBRT_{During/After}$, $Abriaterone_{During/After}$ and $Enzalutamide_{During/After}$.RESULTS: The median follow-up time was 8.3 months (0.4-18.4 months). Fifty-eight (53%) patients received all 6 Ra-223 cycles. Fifty (45%) patients

died, 85 (77%) progressed and 24 (22%) had a bone event. The median OS was 11.7 months, PFS was 4.3 months, TTP was 4.4 months, BeFS was 8.6 months and BMF was 8.6 months.A significant reduction of ALP levels ($p<0.001$) and pain score ($p=0.041$) occurred throughout the Ra-223 cycles. A significant risk of progression was associated with declining ECOG status (HR=3.79; $p<0.001$) and increase in PSA_{DT} (HR=15.82; $p<0.001$).Univariable analysis demonstrated that Ra_{Tot}, $ALP_{Initial}$, $ECOG_{Initial}$, $pain_{Initial}$ and $Abriaterone_{During/After}$ were significantly associated with OS ($p\leq0.008$), PFS ($p\leq0.003$) and BeFS ($p\leq0.020$). Additionally, Ra_{Tot}, $Hb_{Initial}$, $ALP_{Initial}$, $ECOG_{Initial}$, $pain_{Initial}$ and $EBRT_{During/After}$ were associated with BMF ($p\leq0.002$).When adjusting for all covariates, however, only Ra_{Tot} and $Abriaterone_{During/After}$ remained significantly associated with OS (HR=0.56; $p<0.001$; and HR=0.32; $p=0.033$, respectively), PFS (HR=0.67; $p<0.001$; and HR=0.52; $p=0.041$, respectively) and BeFS (HR=0.62; $p<0.001$; and HR=0.32; $p=0.019$, respectively). Additionally, only Ra_{Tot} (HR=0.73; $p=0.025$), $ALP_{Initial}$ (HR=3.11; $p=0.043$) and $EBRT_{During/After}$ (HR=3.62; $p=0.053$) remained significantly associated with BMF. CONCLUSIONS: More Ra-223 cycles were beneficial and reduced the risk of death, progression and the risk of a bone event. The risk of progression was increased 3 times with a declining ECOG status and 15 times with rise in PSA_{DT}. During Ra-223 cycles, the concomitant use of Abriaterone seems to have a beneficial effect while the EBRT increased the risk of BMF.

OP239

Therapy of Metastasized Prostate Cancer Using a Lu-177 Labeled PSMA Inhibitor (I&T): First Dosimetric Results in Patients

C. Schuchardt[1], S. Wiessalla[1], A. Özkan[2], H. R. Kulkarni[1], M. Shahinfar[1], M. Sayeg[1], M. Weineisen[3], H. J. Wester[3], R. P. Baum[1]; [1]THERANOSTICS Center for Molecular Radiotherapy and Molecular Imaging, BAD BERKA, GERMANY, [2]Yildiz Technical University, Department of Physics, Istanbul, TURKEY, [3]Technical University Munich, Pharmaceutical Radiochemistry, Faculties of Chemistry and Medicine, Munich, GERMANY.

Aim: The prostate-specific membrane antigen (PSMA) is significantly over-expressed in prostate cancer cells compared to normal prostate tissue. The aim of our study was to determine the kinetics and dosimetry in patients undergoing peptide radioligand therapy (PRLT) of metastasized prostate cancer using the Lu-177 labeled PSMA inhibitor (I&T: imaging and therapy). Methods: 20 patients with progressive, castrate resistant metastatic prostate cancer (aged 73+/-7 years) were included in the analysis. High PSMA expression was verified before treatment by Ga-68 PSMA PET/CT. The administered activity ranged from 3.6 to 8.6 GBq Lu-177 PSMA. Based on five conjugated planar whole-body scans, time-dependent organ and tumor activities were determined and dosimetric calculations were performed according to the MIRD scheme using OLINDA/EXM software. To analyse the kinetics, we used the following parameters: effective half-life in hours (representing the slower beta-phase) and uptake in %IA (fraction of injected activity), which were calculated using the fit of the time-dependent activity curve to a mono- or bi-exponential function. Blood samples were drawn to determine the blood kinetics and to estimate the absorbed dose to red marrow. Results: Very intense uptake in the tumour lesions as well as significant uptake in the kidneys and the salivary glands was observed in all patients. Blood sampling revealed fast clearance from blood with half-lives of 12min (alpha-phase) up to 42hours (beta-phase). There was rapid clearance of tracer from whole body with a half-life of 12-91hours. The maximum renal uptake was 12%IA and showed a fast wash-out with half-lives of 19-82hours. Parotid glands demonstrated high uptake up to 1.2%IA with half-lives of 32+/-20hours (maximum 118hours). Concerning malignant lesions we distinguished between bone (30) and lymph node (12) metastases. The maximum uptake was 1.6% IA for bone and 1.8%IA for lymph node metastases. All tumour lesions followed an exponential decline with a mean half-life of 60hours. The following organ- and tumour doses were calculated: Whole body 0.03+/-0.02mGy/MBq (0.01-0.07mGy/MBq); kidneys 0.7+/-0.4mGy/MBq (0.2-1.5mGy/MBq); parotid glands 1.4+/-1.3mGy/MBq (0.1-4.8mGy/MBq); bone lesions 0.2-28mGy/MBq; lymph node lesions 0.1-78mGy/MBq. Clinically, no adverse effects were observed in any of the patients concerning renal function (serial follow-up up to 24months) or salivary glands. Conclusions: Despite high uptake in the kidneys and salivary glands, the high tumor uptake, fast renal wash-out and rapid blood clearance confirm the efficacy and safety of PRLT using the Lu-177 labeled PSMA inhibitor PSMA I&T in patients with metastasized prostate cancer.

OP240

Radiation Sensitivity of Prostate Cancer Cells for Beta- or Auger-Electron, Alpha-Particle, or Photon Irradiation.

J. Elgqvist, K. Claesson, E. Larsson, S. Oredsson, O. Vilhelmsson-Timmermand, T. Tran, S. Strand; Institute for Clinical Sciences, LUND, SWEDEN.

Aim. Radioimmunotherapy against prostate cancer is an evolving research area due to the absence of a curative therapy of the metastatic disease. The purpose of this study is to investigate radiation sensitivity of prostate cancer cell lines DU145, LNCaP, and PC3 irradiated with 177-Lu, 111-In, alpha-particles from 241-Am, or 137-Cs. Materials and Methods. The three cell lines DU145, LNCaP and PC3 were irradiated

using an unspecific IgG1 antibody labeled with 177-Lu or 111-In, by external photon irradiation using 137-Cs, or by using an external 241-Am alpha-particle irradiator. The cells were subjected to absorbed doses equal to 0, 0.5, 1, 2, 4, 6, 8, or 10 Gy. For evaluation of cell survival; colony forming and tetrazolium-based assays were used. Regarding the tetrazolium-based assay; after irradiation in 96- or 24-well plates tetrazolium solution was added to each well, incubated, and then measured for level of absorbance at 450 nm, indicating the amount of live/viable cells. Results. For DU145 the SF at 2.0 Gy (SF2Gy) was 0.58 ± 0.06, and 0.40 ± 0.08 (mean ± SEM) after irradiation by 177-Lu or from photons from the LINAC, respectively. Irradiations using 111-In are on-going for DU145. For LNCaP the SF2Gy was 0.62 ± 0.03 for the 177-Lu irradiation. Irradiations using 111-In for the LNCaP cells are on-going. Irradiations of the PC3 cells are also on-going. Irradiations using 241-Am shows a significantly reduced cell survival already at an absorbed dose equal to 2 Gy. Compared to 137-Cs photon irradiations, a preliminary RBE equal to 4-5 is observed for the alpha-particle irradiations of the LNCaP and DU145 cells, at 37% cell survival. Conclusions. A significantly lower SF2Gy value after irradiation with 111-In in DU145 cells, compared to irradiation with 177-Lu or 137-Cs/LINAC is observed. Irradiation using 241-Am show a high level of cell killing efficacy, indicating a potential use of alpha-particle emitters labeled to specific antibodies for the treatment of microscopic prostate cancer. The results indicate that the inherent radiosensitivity of prostate cancer cell lines might vary greatly and that it therefore is very important to consider which type of irradiation to use in targeted radionuclide therapies.

Influence of Histidine-Containing Tags on Biodistribution of Radiolabelled ADAPT-Based Imaging Probes

S. Lindbo[1], J. Garousi[2], M. Åstrand[1], H. Honarvar[2], A. Orlova[2], S. Hober[1], **V. Tolmachev**[2]; [1]Royal Institute of Technology-KTH, Stockholm, SWEDEN, [2]Uppsala University, UPPSALA, SWEDEN.

Aim. ADAPTs are a class of small (~5 kDa) robust scaffold proteins suitable as probes for radionuclide molecular imaging in vivo. The attachment of a histidine-containing tags to the scaffold proteins allows efficient purification by immobilized metal ion affinity chromatography (IMAC) and permits labelling with $^{99m}Tc(CO)_3$. Earlier, we have demonstrated that replacement of the hexahistidine (H_6)-tag with the negatively charged histidine-glutamate-histidine-glutamate-histidine-glutamate (HE_3)-tag reduces hepatic uptake of radiolabelled affibody molecules. The same effect has been confirmed for other scaffold proteins, DARPins, and short peptides. The aim of this study was to evaluate effect of histidine-containing tag composition on biodistribution of ADAPTs. Material and methods. A series of anti-HER2 ADAPT6 probes having DEAVDANS lead sequence and H_6- or HE_3-tags at N-termini has been prepared. In two variants, maleimido derivative of DOTA was conjugated to a unique cysteine was incorporated at N-terminus. DOTA-C-HE_3-ADAPT6 and DOTA-C-H_6-ADAPT6 were labelled with ^{111}In. HE_3-ADAPT6 and H_6-ADAPT6 were labelled with $^{99m}Tc(CO)_3$ using IsoLink kit. Binding specificity, affinity, and cellular processing of new conjugates was evaluated using HER2-expressing SKOV-3 ovarian carcinoma cells. Biodistribution at 1,4 and 24 h p.i. was evaluated in normal NMRI mice. Tumour-targeting properties of the best $^{99m}Tc(CO)_3$-labelled variant, $^{99m}Tc(CO)_3$-H_6-ADAPT6 were evaluated in BALB/C nu/nu mice bearing SKOV-3 xenografts. Results. All radiolabeled ADAPTs demonstrated specific binding to SKOV-3 cells with affinities in the range of 1.1-2.8 nM. The internalization by SKOV-3 cells was slow. In vivo, all conjugates cleared rapidly from blood via kidneys with subsequent renal re-absorption. The hepatic uptake of ^{111}In-DOTA-C-H_6-ADAPT6 was slightly but significantly ($p<0.05$) higher that the uptake of ^{111}In-DOTA-C-HE_3-ADAPT6 at 1 h pi, but biodistribution was very similar at later time points. Surprisingly, the uptake of $^{99m}Tc(CO)_3$-HE_3-ADAPT6 was significantly ($p<0.05$) higher than uptake of $^{99m}Tc(CO)_3$-H_6-ADAPT6 in liver, blood, and bone at 1h p.i. At 4 h p.i., hepatic uptakes were equal, but $^{99m}Tc(CO)_3$-H_6-ADAPT6 provided lower uptake in blood and bone. $^{99m}Tc(CO)_3$-H_6-ADAPT6 demonstrated high (19± 3 %ID/g at 4 h p.i.) and specific tumour uptake. Tumour-to-blood and tumour-to-liver ratios were 102± 29 and 12± 3, respectively. Conclusion. Influence of histidine-containing tag on biodistribution of scaffold proteins depends on composition of a scaffold protein and might differ appreciably. This should be take into account in molecular design of imaging probes based on engineered scaffold proteins.

OP243

Preclinical development of a novel combination therapy against ovarian carcinoma: Combination of anti-L1CAM Lutetium-177 radioimmunotherapy and clinically relevant protein kinase inhibitors

D. Lindenblatt[1], G. Pellegrini[2], S. Cohrs[1], P. R. Spycher[1], D. Vukovic[1], E. Fischer[1], R. Schibli[1,3], **J. Grünberg**[1]; [1]Paul Scherrer Institut, Villigen PSI, SWITZERLAND, [2]Univerity of Zurich, Institut für Veterinärpathologie, SWITZERLAND, [3]Department of Chemistry and Applied Biosciences, ETH Zurich, SWITZERLAND.

Aim: Previously we have shown that paclitaxel improved anti-L1CAM lutetium-177 radioimmunotherapy in an ovarian cancer xenograft model (EJNMMI Research 2014, 4:54). Based on this finding we asked whether the addition of modern and clinical relevant protein kinase inhibitors (PKIs) offers also a therapeutic possibility to improve RIT against ovarian carcinoma. Five PKIs for cytotoxicity screenings were chosen based on their current clinical relevance (clinical phase II-III, ovarian cancer) and their influence on cell cycle regulation and DNA damage repair pathways. We combined selected PKIs with anti-L1CAM monoclonal antibody chCE7 labelled with lutetium-177 for our investigations. Material and methods: PKIs cytotoxicities were determined via cell colony-forming assays. Biomarker of double-strand-breaks (dsDNA breaks; pH2A.X) was analysed by Western blot after single or combined treatments. Levels of histone phosphorylation were quantified by fluorescence microscopy. Flow cytometry analysis was performed to evaluate levels of apoptosis based on combination- or monotreatments. For immunohistochemistry, nude mice (n = 3) were subcutaneously injected with SKOV3ip human ovarian carcinoma cells and treated with 2 MBq ^{177}Lu-DOTA-chCE7 alone or in combination with 60 mg/kg MK1775 administered 72h post radioimmunotherapy. PKI dosages were applied daily for 4 consecutive days. Accordantly, untreated controls received PBS. 6 days post treatment start tumours samples were collected and stained against pH2A.X. Results: *In vitro c*ytotoxicity studies demonstrated that the IC_{50} values of the different PKIs ranging from nanomolar to micromolar concentrations indicating varying sensitivities of ovarian cancer cell lines. Western blot analysis of IGROV1 cell lysates revealed that combination of ^{177}Lu-DOTA-chCE7 (5 MBq/ml) and PKI MK1775 (300 nM) induced higher levels of histone phosphorylation (pH2A.X) compared to either monotreatment. This observation was confirmed and quantified by florescence microscopy demonstrating a significant increase in pH2A.X positive cells (^{177}Lu-DOTA-chCE7 + MK1775: 91.1% vs. ^{177}Lu-DOTA-chCE7: 71.7% and MK1775: 55.5%; $p < 0.05$). Increased amounts of present dsDNA breaks resulted in a significant higher number of early apoptotic tumour cells after combined treatment compared to monotreatments (^{177}Lu-DOTA-chCE7: 7.9%, MK1775: 28.6%, ^{177}Lu-DOTA-chCE7 + MK1775: 40.1%; $p < 0.05$). Pretreated tumour xenografts showed positive stainings for pH2A.X foci indicating present dsDNA breaks in tumour tissue. *Ex vivo* quantification of pH2A.X foci is currently under investigation. Conclusion: The combination of ^{177}Lu-DOTA-chCE7 and protein kinase WEE1-inhibiting MK1775 is a promising treatment strategy against ovarian carcinoma. The amount of induced dsDNA lesions and apoptosis early post treatment start is significantly increased compared to either monotreatment.

OP244

Feasibility of Affibody molecule-based PNA-mediated pretargeting.

H. Honarvar[1], K. Westerlund[2], M. Altai[3], M. Sandström[4], A. Orlova[5], V. Tolmachev[3], A. Eriksson Karlström[2]; [1]Institute for Immunology, Genetics and Pathology, Uppsala University, Uppsala, SWEDEN, [2]School of Biotechnology, Division of Protein Technology, KTH Royal Institute of Technology, Stockholm, SWEDEN, [3]Rudbeck Laboratoriet, Uppsala, SWEDEN, [4]Uppsala University Hospital, Uppsala, SWEDEN, [5]Preclinical PET Platform, Department of Medicinal Chemistry, Uppsala University, Uppsala, SWEDEN.

Aim. Affibody molecules are small (7 kDa) non-immunoglobulin scaffold proteins, which enable high contrast visualization of cancer-associated molecular targets. However, their renal clearance is followed by high renal re-absorption, which prevents their use for radionuclide therapy with residualizing radiometals. To overcome this problem, we tested hypothesis that the use of Affibody-based peptide nucleic acids (PNA)-mediated pretargeting would enable higher accumulation of radiometals in tumors than in kidneys. The aim of this study was to provide a proof-of-principle for Affibody based PNA-mediated pre-targeting. Material and methods. We designed an anti-HER2 Affibody-PNA chimera ZHER2:342-SR-HP1containing 15-mer HP1 PNA recognition tag, and a complementary HP2 hybridization probe. Presence of a tyrosine residue at N-terminus and DOTA-chelator at C-terminus of HP2 permitted labeling with both 125I and 111In. DOTA-chelator conjugated to the N-terminus of ZHER2:342-SR-HP1provided radiolabeling of the chimera with 111In. In vitro binding specificity, affinity, and cellular processing properties of constructs were studied using HER2 -expressing SKOV-3 and BT474 cell-lines. The in vivo targeting specificity and biodistribution profile of ZHER2:342-SR-HP1 and 111In/125I-HP2 were studied in mice bearing SKOV-3 xenografts. Results. 111In-ZHER2:342-SR-HP1 demonstrated specific-binding to HER2-expressing BT474 and SKOV-3 cancer cells in vitro with affinity of 6±2 pM. The binding of radiolabeled complementary PNA probe 111In/125I-HP2 to ZHER2:342-SR-HP1 pre-treated cells was specific with affinity of 200-400 pM. 111In-ZHER2:342-SR-HP1showed specific accumulation in SKOV-3 xenografts in BALB/C nu/nu mice and a rapid clearance from blood. Pre-saturation of SKOV-3 with non-labeled anti-HER2 Affibody or the use of HER2-negative Ramos xenografts resulted in significantly lower tumor uptake of 111In-ZHER2:342-SR-HP1. The complementary PNA probe 111In/125I-HP2 accumulated in SKOV-3 xenografts only in presence of ZHER2:342-SR-HP1, injected 4 h earlier. The tumor accumulation of 111In/125I-HP2 was very low (at the same level as in muscles) without ZHER2:342-SR-HP1 pre-

injection. The uptake of 111In-HP2 in SKOV-3 xenografts was 19±2 %ID/g at 1 h after injection. The uptake in blood and kidneys were ca. 50- and 2-fold lower, respectively. Conclusion. We have shown that the use of Affibody-based PNA-mediated pretargeting enables specific delivery of radionuclides to tumors and provides higher radiometal concentration in tumors than in the kidneys. This opens a way for investigation of such promising therapeutic radionuclides as low energy beta emitter 177Lu, or alpha emitters 212Bi, 213Bi, and 227Th, for Affibody-mediated therapy.

OP245

An Anti-HER2 Nanobody Labeled with 18F Using a Residualizing Label for Assessing HER2 Status

G. Vaidyanathan[1], D. McDougald[1], J. Choi[1], E. Koumarianou[1], M. Pruszynski[2], T. Osada[1], H. Lyerly[1], T. Lahoutte[3], M. R. Zalutsky[1]; [1]Duke University Medical Center, Durham, NC, UNITED STATES, [2]Institute of Nuclear Chemistry and Technology, Warsaw, POLAND, [3]Free University of Brussels, Brussels, BELGIUM.

Aim. A PET imaging method for determination of HER2 status in breast cancer (bc) patients would be highly desirable. Nanobodies (Nbs) are single domain antibodies derived from *Camelidae*. Their small size (~15 kDa), nM-range affinity, low immunogenicity and other properties are very attractive for PET imaging. The goal of this study was to develop an anti-HER2 Nb labeled with ^{18}F using a novel residualizing labeling (RL) strategy as a potential tracer for assessing HER2 status in bc patients. Methods. *N*-succinimidyl 3-((4-(4-[^{18}F]fluorobutyl)-1H-1,2,3-triazol-1-yl)methyl)-5-(Boc_2-guanidinomethyl)benzoate) (Boc_2-[^{18}F]SFBTMGMB) was synthesized by the click reaction of an azido precursor and [^{18}F]fluorohexyne, and treated with TFA to generate the RL [^{18}F]SFBTMGMB. The anti-HER2 Nb 5F7 was conjugated with [^{18}F]SFBTMGMB, and for comparison, with [^{18}F]SFB (non RL) and the previously validated RL, [^{125}I]SGMIB. The labeled nanobodies were evaluated by TCA precipitation, ITLC, and gel electrophoresis. Binding affinity was determined using HER2-expressing BT474M1 bc cells and immunoreactive fraction (IF) by the Lindmo method. Paired-label internalization of [^{18}F]SFBTMGMB-5F7 versus [^{125}I]SGMIB-5F7, and [^{18}F]SFB-5F7 versus [^{125}I]SGMIB-5F7, was evaluated using BT474M1 cells in vitro. Paired-label biodistribution of [^{18}F]SFBTMGMB-5F7 and [^{125}I]SGMIB-5F7 was determined in SCID mice bearing BT474M1 xenografts. Results. Nb 5F7 was labeled with [^{18}F]SFBTMGMB with a conjugation efficiency of 33.4 ± 5.2% (n = 4). TCA precipitation, SDS-PAGE, and ITLC indicated >95% of radioactivity was protein-associated. [^{18}F]SFBTMGMB-5F7 bound specifically to HER2 with 62-84% IF and a Kd of 4.65 ± 0.88 nM. Comparable results were obatined with [^{18}F]SFB-5F7 and [^{125}I]SGMIB-5F7. Paired-label internalization indicated about 50% of initially bound radioactivity was trapped intracellularly for [^{18}F]SFBTMGMB-5F7 and [^{125}I]SGMIB-5F7 over 1-4 h. In contrast, only 39.9 ± 0.3% of [^{18}F]SFB-5F7 was internalized at 1 h and intracellular activity decreased to 24.5 ± 1.1% at 4 h. Tumour uptake of [^{18}F]SFBTMGMB-5F7 in vivo was 29.0 ± 3.9% ID/g and 36.3 ± 14.1% ID/g compared to 26.3 ± 3.1% ID/g and 32.5 ± 12.1% ID/g for [^{125}I]SGMIB-5F7 at 1 h and 2 h, respectively, with tumor:blood ratio for the ^{18}F conjugate increasing from 16.6 ± 5.0 at 1 h to 47.4 ± 13.1 at 4 h . Conclusions. [^{18}F]SFBTMGMB is perhaps the first ^{18}F agent specifically designed for RL properties and shows advantages for this purpose both in tumour cells and xenograft models. Moreover, the [^{18}F]SFBTMGMB-5F7 Nb conjugate is a promising agent that warrants further evaluation for PET imaging of HER2-expressing malignancies.

OP246

DOTAGA vs DOTA: an extra negative charge reduces hepatic uptake of Affibody molecules labelled with 111In and 68Ga

J. Strand[1], H. Honarvar[1], K. Westerlund[2], B. Mitran[3], A. Orlova[3], A. Eriksson Karlström[4], V. Tolmachev[1]; [1]Department of Immunology, Genetics and Pathology, Uppsala, SWEDEN, [2]Division of protein technology, Stockholm, SWEDEN, [3]Preclinical PET Platform, Uppsala, SWEDEN, [4]Division of protein technology, Uppsala, SWEDEN.

Aim: Affibody molecules are small (7kDa) scaffold proteins. Earlier, we investigated the impact of charge, lipophilicity and positioning of different amino acid tags on Affibody targeting properties. We found that the negatively charged variant of tags at N-terminus provide the lowest hepatic uptake. We hypothesize that the N-terminal placement of a chelator providing increased negative charge of a complex with a radionuclide might be used for reduction of liver uptake. To test this hypothesis, we compared targeting properties of anti-HER2 affibody molecules labelled with 111In- and 68Ga using DOTAGA and DOTA chelators. In complexes with trivalent metals, DOTAGA provides an extra negative charge compared with DOTA. Methods: DOTA and DOTAGA were conjugated to N-terminus of synthetic ZHER2:2891 via amide bond. The conjugates were labelled with 68Ga and 111In. In vitro binding specificity and internalization assays were performed using high HER2-expressing SKOV-3 and low HER2 expressing LS174T cells. The tumour targeting and biodistribution properties of 111In- and 68Ga-labelled conjugates were compared in nude mice bearing SKOV-3 xenografts at 2 hours post injection. PET imaging of SKOV-3 xenograft bearing mice

was preformed 2 h after injection of 68Ga-DOTAGA-ZHER2:2891. Results: DOTAGA-ZHER2:2891 and DOTA-ZHER2:2891 were stably labelled with 68Ga and 111In. The radiolabelled conjugates showed preserved binding specificity to HER2-expressing cells in vitro. All conjugates demonstrated slow internalization rates after binding to both SKOV-3 and LS174T cells. In vivo, the tumour uptake was similar, 22±2, 19 ±2, 25±2, and 23±5 %ID/g for 111In-DOTAGA-ZHER2:2891, 68Ga-DOTAGA-ZHER2:2891, 111In-DOTA-ZHER2:2891, and 68Ga-DOTA-ZHER2:2891, respectively. In vivo blocking assay confirmed specificity of tumour targeting. A combination of a nuclide and a chelator had clear influence in biodistribution in normal tissues.111In-labeled conjugates cleared significantly rapider from blood than 68Ga-labelled variants. The use of DOTAGA provided significantly lower hepatic uptake and blood radioactivity concentration for both radionuclides. The most pronounced difference between chelators was in the case of 68Ga. The use of DOTAGA provided appreciably higher tumour-to-blood (61 ±6 vs 23±5, $p<0.05$) and tumour-to-liver (10.4±0.6 vs 4.5±0.5, $p<0.05$) ratios that the use of DOTA. MicroPET/CT imaging confirmed that 68Ga-DOTAGA-ZHER2:2891 can visualize HER2-expressing xenografts with high contrast. Conclusion: This study demonstrated that chelators may be used for modification of uptake of Affibody molecules in normal tissues and improvement of imaging contrast. The use of DOTAGA for labelling with 68Ga resulted in a much better biodistribution profile for Affibody molecules compared with DOTA.

OP247

Generalized syntheses of tumor targeted yolk/shell structured multifunctional nanosystems

F. Chen, H. Hong, S. Shi, H. F. Valdovinos, T. E. Barnhart, W. Cai; University of Wisconsin-Madison, MADISON, WI, UNITED STATES.

Aim: To develop a generally applicable protocol for yolk/shell structured multifunctional nanosystems, to be used for tumor targeted PET image-guided drug delivery. Materials and Methods: Upconversion nanoparticle (UCNP, with NIR-in-NIR-out upconversion luminescence) was used as the initial example. UCNP was first coated with a dense silica ($dSiO_2$) shell, forming UCNP@$dSiO_2$, followed by re-growth of a shell-thickness controllable mesoporous silica nanoshell (MSN) to form UCNP@$dSiO_2$@MSN. A Na_2CO_3 etching protocol was then used to selectively etch away dSiO2, leaving behind yolk/shell structured nanoparticles denoted as UCNP@HMSN. A step-by-step surface engineering process was then adopted to conjugate (or label) NOTA, polyethylene glycol (PEG) linkers, TRC105 (an anti-CD105 antibody), and ^{64}Cu to form ^{64}Cu-UCNP@HMSN-PEGTRC105. Both hydrophobic (i.e. Sunitinib) and hydrophilic (i.e. Doxorubicin) drugs could be loaded inside UCNP@HMSN. Systematic in vivo PET imaging and biodistribution studies were performed in 4T1 tumor-bearing mice to evaluate and confirm tumor targeting capability, validated by in vitro/ex vivo studies. Results: TEM confirmed successful synthesis of UCNP@HMSN. By changing the "yolk" to superparamagnetic iron oxide nanoparticle (SPION) or quantum dot (QD), we confirmed the general applicability of this protocol. In vitro CD105 targeting in HUVEC (CD105+) and MCF-7 (CD105-) cells showed strong/specific binding of FITC-conjugated UCNP@HMSN-PEG-TRC105 to CD105+ cells with negligible non-specific binding. In vivo tumor targeting and PET imaging demonstrated CD105-specific targeting of ^{64}Cu-UCNP@HMSN-PEG-TRC105 in 4T1 tumor-bearing mice, with peak tumor uptake of ~6.5 %ID/g at 6 h post-injection. CD105 specificity was confirmed by blocking and ex vivo histology studies. Conclusion: We report the generalized syntheses of yolk/shell structured nanosystems for tumor targeted PET imaging and drug delivery. With UCNP, QD, SPION, or other nanocrystals inside each yolk/shell structure, this nanoplatform is highly versatile for future tumor targeted multimodality image-guided drug delivery.

Role of [11C]choline PET/CT in tailored Cyberknife stereotactic Therapy in patients with prostate recurrent isolated lymph node.

P. Gandolfo[1], **F. Ria**[2], A. Bergantin[2], A. S. Martinotti[2], I. Redaelli[2], M. Invernizzi[2], A. Vai[2], I. Bossi Zanetti[2], L. C. Bianchi[2], G. Beltramo[2]; [1]Nuclear Medicine Unit - Centro Diagnostico Italiano, Milan, ITALY, [2]Cyberknife Unit - Centro Diagnostico Italiano, Milan, ITALY.

Aim: [11C]choline PET/CT has been established as a diagnostic tool in re-staging patients with biochemical failure after radical treatment for prostate cancer in particular for its capability to detect the presence of lymph node and bone metastases. The knowledge of the anatomical site of recurrence may be useful to refer patients to the specific tailored therapy, in addition to the conventional anti-hormonal therapy. We investigated the role of [^{11}C]choline PET/CT as an image method to select patients for Cyberknife stereotactic tailored therapy. Methods and Materials: Between March 2009 and march 2013 a cohort of 30 patients with up to 3 synchronous lymph node prostate metastases staged with [11C]choline PET/CT (47 lesions, median volume 12,92 cc, range 0,39 -111,67), following biochemical recurrence after local curative treatment were treated with Cyberknife Stereotactic Body Radiotherapy (SBRT) in our Center. In all patients [11C]choline PET/CT images was used to select and delineated target volumes at lymph node recurrent sites. The mean age of patients population at the time of the Cyberknife treatment was 68 years (range 55-84). Cyberknife prescription doses were 3000-3600 cGy delivered in 3 consecutive fractions of 1000-1200 cGy. In 14 lesions (37%) SBRT was performed as re-irradiation (the recurrent lesion was situated in the previously irradiated volume). Results: The Cyberknife treatment was well tolerated without any acute or late toxicity at all. There were no in field recurrence, resulting in a local control of 100%. Eleven and 3 patients, respectively required a second and third salvage treatment for metachronous metastatic disease. The median time to clinical progression was 14 months (range 3-54). After a median follow up of 33 months (range 13-73) 16 patients started with Androgen Deprivation Therapy (ADT) because of polymetastatic disease resulting in an ADT-FS of 80% at 1 year and 65% at 2 years. The median time ADT was deferred resulted of 26 months (range 4-56). Conclusions: The recent evidence of the potential toxic nature of ADT suggest that effective local therapy might reduce the burden of systemic therapies usually given to patients with metastatic prostate cancer. Although there are not literature data that support the use of [11C]choline PET/CT to plan target volume at lymph nodal level our preliminary results are promising, showing that the treatment is well tolerated with excellent rate of local control and suggest a potential role of [11C]choline PET/CT to select and refer patients to specific treatment strategies.

OP250

Comparison of [18F] choline PET/CT with integrated [18F] choline PET/MRI in patients with suspected recurrent prostate cancer.

A. Wetter[1], B. M. Schaarschmidt[2], M. Schenck[3], H. Rübben[3], S. Lütje[4], T. Pöppel[4], M. Forsting[1], T. Lauenstein[1]; [1]University Hospital Essen, Dept. of Radiology and Neuroradiology, Essen, GERMANY, [2]University Hospital Düsseldorf, Dept. of Radiology, Düsseldorf, GERMANY, [3]University Hospital Essen, Department of Urology, Essen, GERMANY, [4]University Hospital Essen, Department of Nuclear Medicine, Essen, GERMANY.

Purpose: To prospectively compare diagnostic performance of [18F] choline PET/CT with [18F] choline PET/MRI in patients with suspected recurrent prostate cancer. Methods: 68 patients were assigned for a clinically indicated [18F] choline PET/CT because of a rising PSA-level after radical prostatectomy. After PET/CT was completed, patients were transferred to the PET/MRI unit and simultaneous [18F] choline PET/MRI examinations were conducted on an integrated PET/MR scanner. Sequence protocol consisted of one pelvic PET scan with an acquisition time of 20 minutes and simultaneous acquisition of T2 and T1-weighted MR images before and after administration of a paramagnetic contrast agent. PET/CT and PET/MR image analysis was prospectively performed by different groups of nuclear medicine physicians and radiologists with respect to the detection of lymph node metastases, bone metastases and local recurrence of the tumor. Results: Simultaneous PET/MRI examinations were successfully accomplished in all patients with diagnostic image quality. [18F] choline PET/CT diagnosed pelvic tumor lesions in 52 patients (76.5%), PET/MRI revealed pelvic tumor lesions in 55 patients (80.9 %). Concordant diagnoses of PET/CT and PET/MRI were achieved in 60 patients, whereas PET/MRI led to a discordant diagnosis in 8 patients (11.8 %). In three patients where no suspicious lesion was detected with PET/CT, PET/MRI led to the diagnosis of a local recurrence in 1 patient and suspected bone metastases in two patients. In the remaining five patients, PET/MRI found additional lymph node metastases in one patient and additional bone metastases in four patients. From a clinical point of view, PET/MRI led to a change of management in 2 patients (2.9 %) Conclusion: Simultaneous [18F] choline PET/MRI is a robust method for clinical use and provides additional information as compared to PET/CT in patients with suspected recurrent prostate cancer. However, a significant change of diagnosis with following change of treatment is observed only in a small percentage of patients.

OP251

Prognostic value of FCH PET/CT in response to radical radiotherapy in patients with localized prostate cancer

M. Sepulcri, A. Negri, E. Agostini, S. Galuppo, A. Cervino, G. Saladini, A. Scaggion, M. Paiusco, L. Evangelista; Istituto Oncologico Veneto I.R.C.C.S., PADOVA, ITALY.

Aim: the aim of this study was to assess the value of FCH PET/CT in predicting the outcome of patients with localized prostate cancer treated by radical radiotherapy.Materials and methods:

from a mono-centric PET/CT database, we retrospectively revised pre-treatment FCH PET/CT scans of 11 patients who underwent radiotherapy (dosage: 78 Gy/39 fractions) for the treatment of localized prostate cancer. For each study, SUVmax, SUVavg and metabolic tumor volume (MTV) were evaluated. Moreover, the value of PSA before radiotherapy (PSAp) was recovered. A follow-up period after PET/CT scan, of at least one-year, was required. In accordance with the observational period, patients were classified as disease free (DF) if the increase of PSA value after radiotherapy was less than 2 ng/mL respect to PSA nadir value, conversely with an increase of PSA higher than 2 ng/ml they were classified as recurrent (not disease free, NDF). A Kolgomorov-Smirnov test was used to compare the distribution of semi-quantitative PET and PSA data of the two patient groups.Results: mean, minimum and maximum values of SUVmax, SUVavg, MTV and PSAp were 9.6 (3.2-22.7), 5.1 (3.0-9.4), 11.1 (0.1-49.1) and 19.5 ng/mL (2.0-73.5 ng/mL), respectively. After one year of follow-up, 7 patients were considered as DF and 4 patients were considered as NDF. The values of DF patients were 6.2 (3.2-12.6), 3.6 (3.0-4.2), 6.0 (0.1-25.8) and 15.6 ng/mL (2.0-54.8 ng/mL) respectively for SUVmax. SUVavg, MTV and PSAp. For NDF patients the corresponding obtained values were 15.5 (10.4-22.7), 7.9 (5.6-9.4), 22.6 (7.1-49.1) and 26.2 ng/mL (5.0-73.5 ng/mL). In NDF patients, the mean values of SUVmax and SUVavg were significantly higher than in DF group ($p<0.05$ and $p<0.01$, respectively) while MTV and PSAp were not statistically different between the two groups.Conclusion: high values of FCH SUVs in prostate cancer of patients who are candidates to radiotherapy result predictive of poor outcome after one year of follow-up. Therefore, the SUV values could be useful to identify those patients who could benefit from a boosted radiotherapy dose to the dominant intraprostatic tumour lesion.

OP252

Predictive role of 11C-Choline PET/CT on the lymph nodal relapse in prostate cancer patients treated by salvage radiotherapy

E. Incerti[1], A. Fodor[2], P. Mapelli[1], C. Fiorino[3], P. Alongi[4], M. Kirienko[4], G. Giovacchini[5], E. Busnardo[1], G. Berardi[2], R. Calandrino[3], L. Gianolli[1], N. Di Muzio[2], M. Picchio[1]; [1]Nuclear Medicine Department, IRCCS San Raffaele Scientific Institute, Milan, ITALY, [2]Radiotherapy Department, IRCCS San Raffaele Scientific Institute, Milan, ITALY, [3]Medical Physics Department, IRCCS San Raffaele Scientific Institute, Milan, ITALY, [4]University of Milano-Bicocca, Milan, ITALY, [5]Department of Radiology and Nuclear Medicine, Stadtspital Waid, Zurich, SWITZERLAND.

Aim: The aim was to investigate the possible association between imaging parameters of 11C-Choline PET/CT (Choline-PET/CT) with survival outcomes: overall survival (OS), loco regional relapse free survival (lRFS), clinical relapse free survival (cRFS) and biochemical relapse free survival (bRFS) in patients with prostate cancer (PCa) treated with helical tomotherapy (HTT) on lymph node (LN) recurrence.Materials and Methods: This retrospective study include 68 patients with PCa (mean age: 68 yrs; range: 51-81 yrs) with biochemical recurrence after primary treatment (median PSA: 2.42 ng/ml; range: 0.61-27.56 ng/ml) who underwent Choline-PET/CT from January 2005 to January 2013. PCa patients presented Choline-PET/CT pathological uptake at LN site, were treated with salvage HTT. Positive pelvic and/or abdominal LNs were treated with a median dose of 65.8 Gy (range: 50.0-74.2) in 28 fractions. PET derived parameters such as SUVmax of the most active lesion, SUVmean of all metabolically active lesions and MTV with a threshold of 40%-50%-60% were calculated. Best cut-off values of PET derived parameters discriminating between patients with/without relapses were assesed by ROC analysis: OS, LRFS, CRFS and BRFS were considered. Univariate and multivariate Cox regression analysis including the most predictive PET derived parameters were performed. Results: Choline-PET/CT showed pathologic LNs in 4 patients at pelvic level, in 5 at abdominal level, in 13 at both pelvic and abdominal, in 46 at abdominal and/or pelvic and/or other sites. With a median follow-up of 20 months (range: 3-97 months). The 2-year OS, LRFS, CRFS, BRFS were 86.7%, 91.4%, 51.5% and 40.0% respectively. Significant best cut-off values could be found for both CRFS/BRFS for MTVs threshold. The most discriminative cut-off, based on the AUC of the ROC curves, was MTV60>0.64cc that also confirmed its independent predictive role in multivariate analysis. No significant cut-off values were found for both SUVmax and SUVmean. A two variable model including MTV60 and PET positive LNs site (pelvic vs extra-pelvic disease) well predicts the risk of relapse (2-year CRFS with 0, 1, 2 risk factors equal to $100 \pm 10.0\%$, $62.1 \pm 11.4\%$ and $11.4 \pm 9.7\%$ respectively, $p<0.0001$). Conclusion: PET derived parameters are predictive of tumor response in PCa patients treated with moderately hypo-fractionated HTT. In particular, MTV60 and extra-pelvic disease are predictive of relapse in PCa patients with LNs recurrent. This information may be useful in assessing the comparative effectiveness of various conventional and emerging treatment strategies, and to determine their ability to stratify patients in clinical trials.

OP253

Dynamic 11C-Choline PET/CT in biochemical relapse of prostate cancer: feasibility, clinical role and potential impact in guiding radiotherapy

P. Alongi[1], M. Spallino[2], E. Incerti[1], L. Gianolli[1], M. Picchio[1]; [1]IRCCS San Raffaele Scientific Institute, Milano, ITALY, [2]University of Milano-Bicocca, Milano, ITALY.

Aim : The real utility of Dynamic-11C-Choline-PET/CT (D-PET) in evaluation of local relapse and pelvic lymph-nodes has not been demonstrated yet. Despite an unconfirmed role, association of D-PET with standard PET/CT acquisition is largely used by several PET centre. The aim of this retrospective study was to assess the clinical use of D-PET in patients (pts) with rising PSA after prostatectomy candidates to radiotherapy (RT). Matherials and Methods : 30 pts with rising PSA (range 0.94-6.5 ng/ml) after prostatectomy who underwent to RT on suspicious local or lymph-nodal disease revealed by 11C-Choline PET/CT, were identified retrospectively in our database. In addition to standard PET/CT acquisition (from vertex to mid-thigh), a post-injection D-PET study was performed focusing on the pelvis. Asymmetry and abnormal 11C-Choline uptake at prostate bed and/or lymph-nodes stations were used to define D-PET positivity. PSA levels and clinical outcome were available for all pts. Results : D-PET showed tracer uptake on the prostate bed confirmed by standard PET/CT acquisition in 7/30 pts; 4/7 showed tracer uptake also on the pelvic lymph-nodes. All these 7/30 pts received RT at the site of suspicious local relapse and/or simultaneous integrated boost on the avid lymph-nodes following reduction of PSA (range 0-0.68ng/ml) and good control of disease (median PFS: 30,5 months). In 15/23 pts D-PET revealed 11C-Choline avid pelvic lymph-nodes that were treated by RT using PET/CT in the planning treatment obtaining sensible reduction of PSA levels and good clinical outcome. Only 4/15 pts had biochemical relapse after long time (PFS >24months). Mimicking a clinical scenario, D-PET was useful in the decision making to discriminate lymph-nodes uptake to urethral urine activity in 3/30 pts and to distinguish inflammatory lymph-nodes in 6/30 pts. These 9/30 pts did not received any local treatment showing no progression of disease during the follow-up. Overall, use of D-PET associated to standard PET/CT did not increase significantly the total time of examination (Mean 21 minutes), showing any difference in radiation exposure. Conclusion : the additional use of 11C-Choline D-PET, demonstrated to be a valuable tool allowing an improved evaluation of relapsing prostate cancer and providing crucial information in guiding radiotherapy.

OP254

11C-choline PET/CT in castrate-resistant prostate cancer patients treated with Docetaxel

F. Ceci[1], P. Castellucci[1], T. Graziani[1], R. Renzi[1], J. J. Morigi[1], G. M. Lima[1], F. Lodi[1], R. Schiavina[2], A. Ardizzoni[3], S. Fanti[1]; [1]Nuclear Medicine - S.Orsola-Malpighi Hospital - University of Bologna, Bologna, ITALY, [2]Department of Urology - S.Orsola-Malpighi Hospital - University of Bologna, Bologna, ITALY, [3]Department of Oncology - S.Orsola-Malpighi Hospital - University of Bologna, Bologna, ITALY.

Aim: to investigate the role of ^{11}C-choline PET/CT in the evaluation of the response to treatment in patients with metastatic castration-resistant prostate cancer (mCRPC) treated with Docetaxel in comparison with PSA response. Material and Methods: inclusion criteria were a) mCRPC with rising PSA levels b) Docetaxel as first line of chemotherapy (Docetaxel=75mg/m2 + prednisone=5mg); c) ^{11}C-choline-PET/CT and PSA values assessments performed before and after Docetaxel administration. 60 patients were retrospectively enrolled (age mean/range=68.9/57-84 years-old). ^{11}C-choline PET/CT (PET1) was performed as baseline before Docetaxel (mean value=2.4 months) and after (PET2) the end of treatment (mean value=3 months). PSA values were measured before (PSA1) (mean value=2.7 months) and after the end of treatment (PSA2) (mean value=2.8 months). PET2 was reported as complete (CR) or partial response (PR) or stable disease (SD). The appearance of a new PET-positive lesion was considered progression disease (PD). PSA-trend was calculated considering absolute values variations between PSA1 and PSA2. PSA-response was considered as a decrease ≥50% between PSA1 and PSA2. Clinical, radiological and laboratory follow-up were: range from 6- to 53 months (mean 13.5 months). Results: the 65%(39/60) of patients showed PD at PET2; 23.3% (14/60) showed a SD, while 11.7% (7/60) showed PR or CR. The 48.3% (29/60) of patients showed increasing PSA trend, while the 51.7% showed decreasing PSA-trend. A PSA-response ≥50% was observed in 41,7% (25/60). Considering the 29 patients with increasing PSA-trend, the 79.3% (23/29) showed PD, while the 20.7 (6/29) showed SD. Considering the 31 patients with decreasing PSA-trend, the 48.4% (15/31) showed PD, the 29% (9/31) showed SD while the 22.6% (7/31) showed CR or PR. Considering the 25 patients with PSA-response ≥50%, the 44% (11/25) showed PD at PET2. All patients with PD at PET2 were confirmed by clinical or radiological follow-up. Conclusion: Our data suggest that the increase in PSA values (increasing PSA-trend) measured after the end of Docetaxel is predictive of PD. In case of decreasing PSA values after therapy (decreasing PSA-trend and PSA-response ≥50%), ^{11}C-choline PET/CT may be useful to identify those patients with PET progression despite PSA response. In our patient series, this event occurred in the 44% of the patients showing PSA response.

OP255

Usefulness of 18F-fluorocholine positron emission tomography - computed tomography in occult biochemical recurrence of prostate cancer. A prospective multicentre study

Q. Gillebert[1], V. Huchet[1], C. Rousseau[2], A. Cochet[3], P. Olivier[4], F. Courbon[5], V. Nataf[1], J. Talbot[1]; [1]Department of Nuclear Medicine, Hôpital Tenon, Assistance Publique-Hôpitaux de Paris, Paris, FRANCE, [2]Nuclear Medicine Department,

Institut de Cancérologie de l'Ouest René Gauducheau, Nantes, FRANCE, [3]Department of Nuclear Medicine, Centre Georges-François Leclerc, Dijon, FRANCE, [4]Department of Nuclear Medicine, Hôpital de Brabois, Nancy, FRANCE, [5]Department of Nuclear Medicine, IUCT-Oncopole/Institut Claudius Regaud, Toulouse, FRANCE.

Introduction: The aim of the study was to evaluate the clinical impact of 18F-fluorocholine (FCH) PET/CT on management of patients with occult biochemical recurrence of prostate cancer (rPCa) after initial radical treatment. Methods: 177 patients with occult biochemical rPCa (mean PSA serum level: 7.5 ng/mL, range 0.5-244) after initial radical treatment were included in this multicentre prospective study, due to negative or inconclusive results of MRI of the pelvis and of bone scintigraphy. All patients underwent FCH PET/CT. To determine its impact on patient management, the referring physicians prospectively filled-in a 1st questionnaire before FCH PET/CT concerning the scheduled patient management and then a 2nd questionnaire about the actual management decided after PET/CT. On basis of data of 6 month post-PET follow-up, an independent panel determined the adequacy of the management decision and, if adequate information was available, site-based and patient-based standard of truth (SOT). If SOT could be obtained, centralised masked reading was performed, to determine diagnostic performance. Results: The positivity rate was 58% (103/177 positive FCH PET/CT). A change in patient management was induced in 98 cases (55%). In 38 patients, physicians changed a palliative treatment for a curative treatment with 23 salvage radiotherapies (S-RT), 8 surgical procedures, 7 high intensity focalised ultrasounds (HIFU). In 5 patients, physicians added a curative treatment (2 S-RT, 2 surgical procedures, and 1 brachytherapy) to androgen deprivation therapy (ADT). ADT was begun after FCH PET/CT in 24 patients. In 10 patients, curative treatment was changed for a palliative treatment. In 12 patients, physicians chose to defer the scheduled treatment (10 ADT and 2 S-RT). Finally, the therapeutic protocol has been modified after FCH PET/CT in 9 patients (6 ADT protocols, 2 S-RT and 1 surgical procedure). After FCH PET/CT, 10 CT scans, 17 MRI and 30 biopsies have been performed. The agreement between FCH PET/CT and the tests was 77%. Of the 177 FCH PET/CT, the induced management decisions were inadequate in 8% (15/177). The SOT could be determined for 70 patients and 72 sites. The patient-based detection rate of recurrence was 73%. The reproducibility between on-site and masked readings of PET was substantial with a Cohen's kappa coefficient of 0.67 (95% CI = 0.50-0.83). Conclusion: FCH PET/CT was a powerful tool to detect biochemical recurrence of PCa, even after negative pelvis MRI or bone scintigraphy. It could increase the effectiveness of therapeutic strategy.

Helical tomotherapy and bone metastases in prostate cancer patients: role of Choline-PET/CT

P. Mapelli[1], V. Gangemi[2], E. Incerti[1], G. Giovaccchini[3], C. Deantoni[4], A. Fodor[4], S. Baldari[2], L. Gianolli[1], N. Di Muzio[4], M. Picchio[1]; [1]Nuclear Medicine Unit, IRCCS San Raffaele Scientific Institute, Milano, ITALY, [2]Nuclear Medicine Unit, Department of Biomedical Sciences and of Morphologic and Functional Images, University of Messina, Messina, ITALY, [3]Department of Nuclear Medicine and Radio-Oncology, Stadtspital Triemli, Zurich, SWITZERLAND, [4]Radiation Oncology Department, IRCCS San Raffaele Scientific Institute, Milano, ITALY.

Aim. The number of metastases may reflect the biological aggressiveness of the tumor and may determining the possibility of curative potential interventions such as surgery or high-dose targeted radiotherapy (RT). The aim of the present study is to evaluate the efficacy of Choline-PET/CT based helical tomotherapy (HTT) as an innovative therapeutic approach on bone metastases, in a cohort of prostate cancer (PCa) patients with a limited number of metastases. Materials and methods. This retrospective study included 20 PCa patients presenting biochemical relapse of disease (value of the PSA > 0,2 ng/mL) after primary treatment who underwent Choline-PET/CT and to HTT treatment, from 2007 to 2014. Radiotherapy treatment was delivered with a median dose of 71±5 Gy (range: 60-76) and 51 Gy (range: 30-60) on prostatic bed, LN and bone metastases respectively. All patients underwent to androgen deprivation therapy (ADT) and this treatment was not discontinued for the whole duration of the study. The effectiveness of the treatment was assessed with biochemical response at 3/6/12 months, biochemical relapse-free survival (bRFS) and overall survival (OS) at 1-2 years. Results. The median age at Choline-PET/CT was 67 (range: 51-79). Nine/20 (45%) patients had only bone disease while 11/20 (55%) had disease at bone and lymph nodes (LN). Nineteen/20 patients underwent HTT on prostatic bed, pelvic LNs and bone metastases and 1/20 patient was subjected HTT only on bone. Treatment on the prostatic bed and pelvic lymph node was performed regardless the Choline-PET/CT findings in those sites. In addition, 6/20 patients who presented extra-pelvic LNs detected on Choline- PET/CT, HTT was performed on these sites. The mean follow-up from primary treatment was 56 months (range: 6-179 months) with median of 38 months. At 3 months the biochemical complete or partial response was 82%, at 6 months was 82% and at 12 months was 63%; bRFS at 1-2 year was 55-30% respectively; OS at 1-2 year was 100% and 92% respectively. Conclusion. Choline-PET/CT based HTT is a valid therapeutic approach in PCa patients with a low volume of metastases after primary treatment and biochemical relapse of disease. Further studies are

needed to confirm our results and to stratify PCa patients that may have benefit from this therapeutic approach based on specific clinical and imaging features.

The Clinical Impact of Tc-99m HDP SPECT-CT in the diagnosis and management of complex foot and ankle pathology

C. Tang[1], K. Alsey[2], H. Zaw[2], M. Nathan[1]; [1]Royal Free Hospital, London, UNITED KINGDOM, [2]Hillingdon Hospital, London, UNITED KINGDOM.

Aims: Complex foot and ankle pathology can pose a diagnostic challenge to the clinician. SPECT-CT imaging is being increasingly used as a problem solving tool in these challenging cases, usually when other imaging modalities have been inconclusive.The aims of this study were:1.To evaluate the diagnostic utility of SPECT-CT in identifying potential pain generating pathology2.To determine the influence of SPECT-CT in directing subsequent patient management3.To evaluate patients' clinical outcomes where management was directed by SPECT-CT. Materials and Methods: Between June 2012 and December 2014, 61 consecutive patients (39 females and 22 males, age range 17-85) who were assessed by specialist foot and ankle surgeons and who were subsequently referred for Tc-99m HDP SPECT-CT were included. In total, 65 SPECT-CT scans were identified. Patients were divided into subgroups depending on the scan indication:1. Localisation of probable symptomatic site (43 scans)2. Non-union of fusion (14 scans)3. Metalwork related problems (5 scans)4. Infection (3 scans). The diagnostic utility SPECT-CT, impact on subsequent management and patient outcomes were assessed through correlation of SPECT-CT reports with serial post imaging clinic letters and discussion of individual cases with the orthopaedic surgeons. Results: SPECT-CT was considered diagnostically useful in 86% (56/65) scans : 79% (34/43) of localisation of symptomatic site scans and 100% in all other categories.SPECT-CT influenced subsequent patient management in 57/65 scans: 37% (24/65) further surgery, 8% (5/65) planned surgery, 22% (14/65) therapeutic steroid inject0ions and 22% (14/65) conservative treatment.Of 36 patients who had active intervention, 11/36 (31%) had successful outcomes following surgery, 10/36 (28%) following steroid injections. 14 patients who had conservative treatment were all considered to have had successful outcomes as they were not re-referred to orthopaedics. Conclusion: SPECT-CT was considered diagnostically useful in the majority of cases, particularly for non-union, metalwork problems and infection. SPECT-CT was also clinically useful in subsequent patient management by directing patients towards active surgical intervention or conservative management. Patient outcomes following surgical intervention were mixed, the reasons for which are multifactorial. Nevertheless, this study demonstrates that SPECT-CT has an important role as problem solving tool in the investigation of complex foot and ankle pain.

OP258

Altered bone metabolism of the spine in ankylosing spondylitis demonstrated by ^{18}F-fluoride PET/CT - A novel evaluation tool in patients with relatively low modified Stoke Ankylosing Spondylitis Spine Scores

J. Kim, Y. Choi, S. Lee, Y. Joo, T. Kim; Hanyang University Medical Center, Seoul, KOREA, REPUBLIC OF.

Objectives: The purpose of this study was to identify alterations of bone metabolism of the spine in patients with ankylosing spondylitis (AS) by ^{18}F-fluoride PET/CT and to consider its potential role in the assessment of AS. Methods: Thirty-three consecutive AS patients with inflammatory back pain were included in this prospective study. Clinical disease activity was assessed using the Bath AS Disease Activity Index (BASDAI) and the Korean version of the Bath Ankylosing Spondylitis Functional Index (KBASFI). The presence of altered bone metabolism activity on ^{18}F-fluoride PET/CT was assessed in posterior structures of the spine [cervical, thoracic and lumbar facet joints (FJs), costovertebral joints (CVJs), costotransverse joints (CTJs)] and anterior discovertebral units (DVUs) of vertebral body. Clinical disease activity parameters and ^{18}F-fluoride PET/CT findings were compared in patients with different extents of spinal structural changes on radiography as assessed by the modified Stoke AS Spinal Score (mSASSS) [low change : mSASSS (≤9); high change: mSASSS (>9)]. Results: Altered bone metabolism in the posterior structures of the spine on ^{18}F-fluoride PET/CT were found in most of the patients (27/33, 81.8%) and there was no difference between the two subgroups [low mSASSS, 10/12, 83.3% vs. high mSASSS, 16/18, 88.9%, respectively]. Altered bone metabolism in the anterior DVUs was frequently detected in the mid-thoracic spine, especially T4/T5 level, and differed between the subgroups [low mSASSS, 1/12, 8.3% vs. high mSASSS, 11/18, 66.1%]. In the low mSASSS subgroup, the presence of alterations of bone metabolism in posterior structures, especially FJs, was associated with clinical disease activity scores on the BASDAI and/or KBASFI. Conclusions: ^{18}F-fluoride PET/CT provides additional information about

alterations of bone metabolism in the spine compared with currently used methods of identifying anatomical structural changes. Altered bone metabolism on ^{18}F-fluoride PET/CT is frequently seen in posterior structures of the spine even in the patient with low mSASSS. Moreover, in these patients, metabolic abnormality of the FJs is associated with daily clinical problems. In a single session, ^{18}F-fluoride PET/CT could be used to investigate alterations of posterior structures of the spine, including T-spines, which are underestimated by the mSASSS system. We suggest that popularization of ^{18}F-fluoride PET/CT might contribute to the early diagnosis and evaluation of disease activity, especially in AS patients with low mSASSS.

OP259

99mTc-labelled D-Glucosamine Uptake Reflects Disease Activity in Patients with Ankylosing Spondylitis and Rheumatoid Arthritis

S. Angelides, A. Markewycz, N. Manolios, M. Ali, K. Pavic, R. de Costa, B. Camden; Westmead Hospital, Westmead, AUSTRALIA.

Background: Currently, assessment of disease activity in inflammatory arthritic conditions such as rheumatoid arthritis (RA) and ankylosing spondylitis (AS) is suboptimal. Subclinical disease is not infrequently under-estimated. This study evaluated the clinical utility of a novel radiotracer, 99mTc-Glucosamine, in the assessment of disease activity for both RA and AS.Methods: 30 RA patients (11 male, 19 female) and 12 patients with AS (all male) of various stages of disease were recruited into the study. 99mTc-Glucosamine was prepared in-house and patients received 600 MBq intravenously. Whole body and static images were acquired at 15 min and 3 hr later, using a dual-head Siemens Symbia SPECT/CT gamma camera. Images were analysed by a nuclear physician and each joint given a score (0-5) based on the tracer uptake. A similar scoring system was used for bone scans. A clinical score (0-3) was given, based on the number of tender and swollen joints present, by a rheumatologist. An MRI score of 0-5 was given for each imaged joint that was screened. Glucosamine scans were then compared to other routinely used tests, including haematological, biochemical and autoimmune serological parameters, MRI, and bone scans, and correlated with clinical activity.Results: Optimal images were obtained at 3 hr post-injection in all patients. 99mTc-Glucosamine scans were more adept at identifying active disease and differentiating inflammatory manifestations of disease from non-inflammatory causes. In AS patients, active sacro-iliitis was observed in three patients on the 99mTc-Glucosamine scans. In RA, 99mTc-Glucosamine accumulated at all known sites of disease involvement, and was most pronounced in patients with active untreated disease. Using Spearman's correlation co-efficient, there was a positive correlation between glucosamine scan scores, CRP ($p=0.048$) and clinical assessment ($p=0.003$) that was not noted with bone scans.Conclusion. The radiotracer was well tolerated with no adverse events. 99mTc-Glucosamine imaging can detect spinal inflammation in AS, while plain X-rays and MRI were useful in the detection of chronic related changes. Bone scan changes in the SI joints persist longer than those seen on 99mTc-Glucosamine imaging, and thus were less sensitive in tracking changes in the clinical course. With respect to RA, 99mTc-Glucosamine scans correlated well with the clinical evaluation of patients and were superior to bone scans for imaging inflamed joints. Unlike MRI, which is excellent for imaging specific joints, 99mTc-Glucosamine imaging gives a good overall clinical picture of the patient and correlates well with the clinical activity warranting further evaluation.

OP260

Bone SPECT-CT in the diagnosis and management of facial asymmetry due to mandibular condylar hyperplasia

L. Mohamed Salem, **Sr.**, M. Ibañez Ibañez, V. Godoy Bravo, L. Álvarez Nieto, R. Reyes Marles, D. Segarra Fenoll, M. Castellón Sanchez, P. Nicolas Ruiz, L. Frutos Esteban, J. Navarro Fernandez, M. Murcia Durendez, A. Montellano Fenoy, M. Claver Valderas, M. Roldan Rubio, A. Abella Tarazona; Hospital Clínico Universitario Virgen de la Arrixaca, Murcia, SPAIN.

Aim:To assess the value of Bone SPECT-CT, in the diagnosis and management of facial asymmetry, due to mandibular condylar hyperplasia.Materials and methods:Together with the Oral and Maxillofacial Surgery Department of our hospital, we study retrospectively 99 studies belonging to 73 patients with mean age 24.2 years, who underwent a Bone SPECT-CT with Differential Condylar Quantification (DCQ), considering a DCQ $\geq$ 55% suggestive of active condylar hyperplasia (CH), 46 patients had a normal study and 27 had abnormal one, 10 patients of 27 with abnormal study had several follow-up studies with at least a 6 month-interval, and 8 patients of 46 patients with normal studies.Patients with normal study (inactive CH) and with abnormal study who had a normal follow-up study were referred for mandibular osteotomy for the correction of facial asymmetry.Patients with abnormal study and signs of progression of the disease were referred for condylar shave first, then for mandibular osteotomy in a second time.Results:7 of 10 patients with a first abnormal study had a normal follow-up study a second, third or forth study, until

Differential Condylar Quantification drop down to values considered as normal.3 of 10 patients with a first abnormal study had progression of the disease.8 patients with a first normal study had normal follow-up study.3 patients of 10 were referred for condylar shave (30% of patients with abnormal study who had follow-up).Conclusion:Bone SPECT-CT with Differential Condylar Quantification is a sensitive method to exclude active condylar hyperplasia in patients with facial asymmetry.Practicing follow-up Bone SPECT-CT can avoid unnecessary condylar shave in 70% of the patients with active condylar hyperplasia.

OP261

Optimising Quantitative SPECT in Condylar Hyperplasia

D. O. Hall, A. Demmery, J. Kabala; UH Bristol NHS FT, Bristol, UNITED KINGDOM.

Aims: The intensity of uptake in the abnormal condyle in bone SPECT of condylar hyperplasia can be used as a biomarker for disease progression. In our institution, SPECT/CT is used for older teenagers and adults, and SPECT only for younger patients.Studies can be quantified to give additional information. Methods suggested have included % uptake on abnormal side, ratio to clivus, and ratio of abnormal to normal side; previous studies have used 2D analysis and SPECT only, whereas in this study we have considered 3D analysis and SPECT/CT. This study was carried out to determine whether 3D quantification of SPECT bone studies in condylar hyperplasia is affected by using CT Attenuation Correction (CTAC) and by peak or mean count over each condyle.Materials and methods: 13 clinical studies using Tc-99m HMDP SPECT and SPECT/CT carried out in a single institution in 2014 for unilateral condylar hyperplasia were analysed. 10 were SPECT/CT and 3 paediatric studies were SPECT only. All studies were acquired on a Siemens Symbia T16 system. Volumes of Interest at 40% of maximum count were drawn over both condyles and over the Clivus in 3D using Siemens Syngo Volumetric Analysis, and the peak and mean count were recorded. Results were expressed as % of uptake on abnormal side compared with abnormal, ratio to clivus, and ratio of abnormal to unaffected side. Results were compared between CTAC and Non-AC and peak versus mean count.Results and Conclusions: The ratio of peak or mean condylar count to clivus was significantly affected ($p<0.05$) by use of CTAC, so different normal ranges would be needed in each case; this also suggests that this method would not be good for SPECT-only, as the ratio would vary from patient to patient. Measurements of % uptake on each side and ratio of abnormal to normal were not significantly affected by CTAC or use of peak or mean count. However, there were individual differences which might affect results in a particular case, so methods used should be standardised.

OP262

Clinical value of SPECT/CT in the 'unhappy' total knee arthroplasty (TKA)- a prospective study in a consecutive series of 100 painful knees after TKA

M. T. Hirschmann[1,2], H. Rasch[3]; [1]Kantonsspital Baselland (Bruderholz, Liestal, Laufen), Department of Orthopaedic Surgery and Traumatology, Bruderholz, SWITZERLAND, [2]University, Basel, SWITZERLAND, [3]Kantonsspital Baselland (Bruderholz, Liestal, Laufen), Institute of Radiology and Nuclear Medicine, Bruderholz, SWITZERLAND.

Bone SPECT/CT is considered as beneficial in unhappy patients with pain, stiffness or swelling after total knee arthroplasty (TKA). The purpose of this study was to identify typical pattern of bone tracer uptake (BTU) distribution and intensity values in patients after TKA. The above findings were correlated with the type and fixation of TKA, the time from TKA and intraoperative findings at revision surgery. A total of 100 knees of 84 consecutive patients (mean age±SD 70 ±11 years) after TKA with persistent knee pain were prospectively included. All patients underwent clinical examination, standardized radiographs and Tc-99m-HDP-SPECT/CT as part of a routine diagnostic algorithm. The diagnosis before and after SPECT/CT and final treatment were recorded. TKA component position was determined on 3D reconstructed images. Intensity and anatomical distribution of BTU was determined. Maximum intensity values were recorded as well as ratios in relation to the proximal mid-shaft of the femur. Univariate analyses (Chi square test, Pearson correlation, t-test for independent samples) were performed ($p<0.05$). SPECT/CT changed the clinical diagnosis and final treatment in 85/100 (85%) knees. Intraoperative findings confirmed the preoperative SPECT/CT diagnosis in 32/33 knees (97%). TKA loosening as well as progression of patellofemoral OA was correctly diagnosed in 100% of knees. Typical patterns of BTU for specific pathologies were identified. Loose femoral TKA components significantly correlated with increased BTU at the lateral femoral regions ($p<0.05$). Loose tibial TKA components significantly correlated with increased BTU at all tibial regions ($p<0.05$) and around the tibial peg ($p>0.01$). In conclusion, the diagnostic benefits of SPECT/CT in patients after TKA have been proven. Typical pathology related BTU patterns were identified, which will improve reporting quality. Due to the benefits in establishing the correct diagnosis SPECT/CT it should be part of the routine diagnostic algorithm for patients with pain after TKA.

OP263

Multimodality work-up of patients with suspected infected hip prosthesis: radiography, ESR/CRP testing, joint aspiration, and 18F-FDG PET/CT

W. Broos, R. Kwee, J. Geurts, S. Vöö, B. Brans, R. Weijers; Maastricht UMC, Maastricht, NETHERLANDS.

Objective. To investigate the relative contributions of radiography, ESR/CRP testing, hip joint aspiration, and 18F-FDG PET/CT in the work-up of suspected infected hip prosthesis.Methods. In 45 hips of 45 consecutive patients (58% males, mean age 67 years, range 35-82), the relative contributions of radiography, ESR/CRP testing, synovial fluid culture and white blood cell (WBC) count after joint aspiration, and 18F-FDG PET/CT to the diagnosis of periprosthetic joint infection (PJI) were assessed using stepwise multiple regression analysis. Cultures of synovial fluid and periimplant tissues after revision surgery or clinical follow-up ≥6 months served as reference standard.Results. Synovial fluid culture (B=0.4553, standard error (SE)=0.1241, P=0.0011) and 18F-FDG PET/CT (B=0.5340, SE=0.1523, P=0.0017) were independent tests associated with the diagnosis of PJI. Radiography, ESR, serum CRP, and WBC count of synovial fluid were not independent distinguishing tests. When either a positive synovial fluid culture or positive 18F-FDG PET/CT result were considered positive for PJI, a sensitivity of 96.2% (95% confidence interval [CI] 81.1-99.3%) and specificity of 33.3% (95% CI 13.8-60.9%) were yielded. When the combination of both a positive synovial fluid culture and positive 18F-FDG PET/CT result were considered positive for PJI, a sensitivity of 69.6% (95% CI 49.1-84.4%) and specificity of 100% (95% CI 70.1-100%) were yielded.Conclusion. Synovial fluid culture and 18F-FDG PET/CT were found to be the only independent tests associated with the diagnosis of infected hip prosthesis. PJI is very likely when both tests are positive and very unlikely when both tests are negative.

OP264

The evolution of radiologically occult bone metastases detected on FDG-PET/CT

P. Martineau, M. Pelletier-Galarneau, X. Pham, A. Sheikh; The Ottawa Hospital, Ottawa, ON, CANADA.

Background: FDG-PET/CT is widely used for the staging of malignancies. Occasionally, focal FDG uptake within bone or bone marrow is present on the PET component of the exam without corroborative findings on the co-registered CT. Such findings often requires biopsy, further characterization with MRI, or followup imaging to elucidate their true significance.Methods: We reviewed all FDG-PET/CT reports from our institution dated between 9/1/2012 and 4/2/2015 (N=4280) and identified all patients with focal bone uptake without corroborative findings on the co-registered CT (N=75, 1.8%). For these patients, follow-up imaging was reviewed in order to determine the nature of the PET finding.Results: A total of 89 lesions in 75 patients were identified as 'suspicious for early osseous metastases' due to focal FDG uptake and absence of corroborative findings on the co-registered CT. The mean SUV of these lesions was 4.6 (range 1.5-22.5). 32 (43%) of these patients had followup imaging allowing for reassessment of the lesion site at multiple time points. Of these, 20 (63%) subsequently developed osseous metastases visible on conventional imaging, with aggressive lesions visible on CT (n=11), MRI (n=7), PET-CT (n=1), and plain film (n=1) an average of 160, 88, 39, 812, and 88 days, respectively, following the initial staging PET-CT. The mean SUV of these lesions was 5.6 (range 2.2-22.5). Of the remaining 12 patients, no aggressive osseous lesions were visible on followup MRI (n=1) at 75 days or on CT (n=11) an average of 417 days (range 229-597) following the PET. The mean SUV of these lesions was 3.6 (range 1.5-6.4).Conclusion:Our results show that the majority (63%) of our patients with suspected early osseous metastases developed disease which eventually became visible on conventional imaging; however, a significant portion (37%) of patients with suspected osseous lesions failed to develop radiologically apparent disease. Whether this was due to false-positive PET, false-negative CT/MRI findings, response to treatment or a combination of these factors is unclear. Lesions which became apparent on followup imaging generally had higher SUVs; however, significant overlap in the range of SUVs of those lesions which become apparent and those that remain occult limits the predictive power of SUV in this context. Our findings are of particular significance to those institutions which use PET for initial staging, but perform follow-up with conventional imaging. Our results suggest that, in cases of 'early osseous metastases', corroboration with MRI or biopsy is strongly recommended to ensure proper staging.

Novel treatment strategy for glioblastomas using Auger-electron therapy and concomitant chemotherapy - in vitro studies

A. Therkelsen[1], B. B. Olsen[1], B. Halle[2], P. Høilund-Carlsen[1], H. Thisgaard[1]; [1]Department of Nuclear Medicine, Odense University Hospital, Odense, DENMARK, [2]Department of Neurosurgery, Odense University Hospital, Odense, DENMARK.

Introduction: Glioblastomas (GBM) remains non-curable by conventional treatment strategies. Due to their infiltrative growth, complete resection is not possible and chemo- and radiotherapy are dose limited. A promising treatment strategy is convection-enhanced delivery of the Auger-electron-emitting thymidine analog [125I]5-Iodo-2'-deoxyuridine (125I-UdR) into the tumor site of the brain. By combining this therapeutic approach with concomitant thymidylate synthetase-inhibition of the GBM cells, a further increase of the therapeutic effect can be expected due to an increased DNA-incorporation of 125I in the tumor cells (1). Using viability- and radioactivity uptake assays to analyze a patient-derived GBM cell line in vitro we aimed to elucidate the individual and combined effects of exposure to the therapeutic components: Thymidylate synthetase-inhibition using methotrexate (MTX) or 5-fluoro-2'-deoxyuridine (F-UdR), Auger-electron-therapy using 125I-UdR, and the currently clinically used first-line chemotherapeutic agent temozolomide (TMZ).Material and methods: The human derived cell line T87 was used in all assays and cultured as spheroids in serum free medium. Cellular 125I-UdR uptake assays were performed after a 4 hour co-incubation with 18.5 kBq/mL 125I-UdR and various concentrations of MTX or F-UdR. CellTiter-Blue assays were used to determine cell viability after incubation with 125I-UdR, MTX/F-UdR, and TMZ for 7 days.Results: Radioactivity uptake assays showed that F-UdR was more potent than MTX to increase the uptake of 125I-UdR in the GBM cells. Cells treated with 1 nM F-UdR incorporated 1.8-fold more 125I-UdR than cells treated with 1 nM MTX and cells treated with 125I-UdR alone. A 1000 fold higher MTX concentration, i.e., 1 μM was required to achieve the same increase in 125I-UdR uptake as found using F-UdR. Viability assays showed no viable GBM cells after exposure to 0.01 μM or more MTX/F-UdR for 7 days, demonstrating the toxic effects of these compounds. Exposure to TMZ and 125I-UdR alone showed therapeutic effects with IC50 values of 206 μM (198-214 μM) and 109 Bq/mL (99-120 Bq/mL), respectively. By combining TMZ and 125I-UdR a further decrease in GBM cell viability was found, but no sign of synergy between the two compounds was observed.Conclusion: Concomitant F-UdR resulted in a high increase of 125I-UdR uptake in the GBM cells and at much lower doses than MTX. Exposure to TMZ and 125I-UdR showed strong therapeutic effects, albeit without signs of synergy between the two compounds.References: (1) Kassis et al: Acta Oncol. 2000;39(6):731-7.

OP276

The effects of dose-rate on radiation induced platelet toxicity in internal radiotherapy.

J. Rousseau[1], S. Becavin[1], F. Nguyen[1], N. Sas[1], M. Magnen[1], M. Bourgeois[2,3,4], M. Meckel[5], F. Roesch[5], N. Chouin[6,4]; [1]LUNAM Université, Oniris, "AMaROC", Nantes, FRANCE, [2]CRCNA, INSERM, Université de Nantes, UMR_S 892, Nantes, FRANCE, [3]ARRONAX cyclotron, Saint Herblain, FRANCE, [4]CHU Nantes, Nuclear medicine department, Nantes, FRANCE, [5]Institute of Nuclear Chemistry, Johannes-Gutenberg-University Mainz, Mainz, GERMANY, [6]LUNAM Université, Oniris,, Nantes, FRANCE.

Aim: We investigated the impact of bone marrow (BM) dose-rate variations on mouse thrombopoïesis in a context of internal radiotherapy. Material and Methods: Mice were injected with osteotropic agents: 18F-Na (37-60MBq) or bisphosphonates (BP) labelled either with 64Cu (15-50MBq) or 90Y (0.8-4.9MBq). Biodistributions were determined by counter measurements and cumulated activities within bones were calculated. Dosimetry was performed using a representative mouse CT image integrated into GATE. Absorbed doses were determined for the entire BM or the femur one. Hematological toxicity was monitored via platelet counts over time after injection. BM toxicity was assessed by femur histology and via progenitor colony assays. Experimental data were compared to simulations of a thrombopoïesis compartmental model previously published. It is based on the linear-quadradric model and considers kinetics of BM cell proliferation, differentiation and radiosensitivities.Results: For each radiopharmaceutical, dose-effect relationships on depletion and recovery were demonstrated for BM cells and platelets. Irradiation dose-rates were different for the three radionuclides as 98% of the absorbed dose was deposited in 0.5, 3 and 15 days for 18F-Na, 64Cu-BP and 90Y-BP. A same absorbed dose to the BM of 4.3±0.3 Gy lead to depletions of 65% for 18F-Na and 64Cu-BP versus 40% for 90Y-BP between 7 and 10 days post-injection. Platelet kinetics and depletions were very similar for mean absorbed doses around 4.5±0.3 Gy of 18F-Na or 64Cu-BP and 14.2±2.7 Gy of 90Y-BP.Same dose-rate effects were noticed for the BM cells and the hematopoietic progenitor depletions. Similar progenitor depletions (86-88%) were observed following absorbed doses delivered to the BM of 1.6±0.3 Gy for 18F-Na or 64Cu-BP and 5.5±0.5 Gy for 90Y-BP. Progenitor kinetics were also different: a faster but incomplete recovery (even at

day 46) was observed following a 90Y-BP irradiation whereas the recovery was complete at day 21 for 18F-Na and 64Cu-BP.The compartmental model predicted platelet kinetics and depletions for the three radiopharmaceuticals except for higher doses of 90Y-BP. Despite the simulated decrease of progenitors radiosensitivity in the case of the protracted 90Y irradiation, the model was still unable to accurately predict platelet kinetics or the fastest progenitor recovery. These results highlighted the possibility of a radiobiological process which is not considered in the compartmental model in addition to dose-rate effects.ConclusionWe experimentally demonstrated a significant impact of the dose-rate on BM cells and platelets. A potential adaptive biological process during the Y90 long-lasted irradiation could be involved in this effect.

OP277

Different DNA Damage Repair Rates in Blood Lymphocytes after Peptide Receptor Radionuclide Therapy and Radioiodine Therapy of Thyroid Cancer

U. Eberlein[1], C. Nowak[2], C. Lapa[1], C. Bluemel[1], M. Peper[2], R. A. Werner[1], A. K. Buck[1], H. Scherthan[2], M. Lassmann[1]; [1]Department of Nuclear Medicine, University of Würzburg, Würzburg, GERMANY, [2]Bundeswehr Institute of Radiobiology affil. to the Univ. of Ulm, Munich, GERMANY.

Objectives: Radiation-induced DNA double strand breaks (DSBs) cause, in their vicinity, the phosphorylation of the histone H2AX (then called γ-H2AX) and the accumulation of the 53BP1 protein that binds to and signals damaged chromatin at a DSB site. This leads to the formation of microscopically visible nuclear foci containing both markers, which thus mark radiation-induced DSBs. The aim of the study is to describe the time course of DNA damage in blood lymphocytes in molecular radiotherapy after internal irradiation with I-131 and Lu-177. Methods: We investigated blood samples of patients either after their first peptide receptor radionuclide therapy (PRRT) or their first radioiodine therapy (RIT) of differentiated thyroid cancer (DTC). The average frequencies of radiation-induced foci (RIF) containing both γ-H2AX and 53BP1 fluorescence were determined in the nuclei of two-colour immunostained γ-H2AX/53BP1 lymphocytes isolated from peripheral blood samples of patients before and after molecular radiotherapy (MRT). The foci containing both DSB markers were scored manually in a fluorescence microscope equipped with a red/green double-band-pass filter by an experienced observer. The individual background focus rate was determined in a sample taken prior to therapy. The EANM SOP for DTC was followed to determine the absorbed dose to the blood. The number of RIF as a function of time was described by combining a linear dose-dependent increase with a multi-exponential function characterizing different rates of DNA repair. Results: 283 blood samples (at least 6 per patient) of 36 patients (PRRT: 16, RIT: 20) up to 168h after therapy were evaluated. At late time points (10-12h) after therapy the decay of the average RIF number per cell is best described by a mono-exponential decay function with a decay constant of 0.04h-1. When the absorbed dose to the blood exceeded 20mGy in the first hour, only seen in patients with DTC, we observed the on-set of a fast repair component with a fast decay rate of 0.33h-1 resulting in a bi-exponential decay function. Conclusions: This analysis provides a comprehensive description of the time course of the number of radiation-induced DNA damage foci after molecular radiotherapy of beta emitters. It furthermore reveals a threshold dose for the induction of a fast repair component after in vivo DSB induction by incorporated I-131.

OP278

Impact of Bi-Exponential Repair Kinetics of Sub-lethal Damage on the Relative Effectiveness in Molecular Radiotherapy

A. Malaroda[1], A. J. Green[2], A. B. Rosenfeld[1]; [1]University of Wollongong, Wollongong, AUSTRALIA, [2]National Physical Laboratory, Teddington, UNITED KINGDOM.

AIMS: In Molecular Radiotherapy, the rate of production of sub-lethal lesions competes with the rate of their repair, moreover each type of lesion is characterised by their specific production and repair rates. For example, there is evidence that the repair kinetics in mouse kidney cells is at least bi-exponential, with a fast (<1 h) and a slow (>2h) component. The aim of this study was to compare the impact on the Relative Effectiveness, and by extension on the Biologically Equivalent Dose (BED), of bi-exponential repair kinetics with respect to the widely accepted mono-exponential repair rate. METHODS: The Linear Quadratic model takes the repair rate of sub-lethal lesions into account through the Lea-Catcheside time protraction factor. Thus, Lea-Catcheside factor (G) and Relative Effectiveness (RE) were calculated for a bi-exponential repair rate of constants 0.15 h (fast) and 5.03 h (slow), data published in the literature for mouse kidney cells. Partition coefficients, for the fast and slow components respectively, of [0.5,0.5], [0.25,0.75], [0.75, 0.25], [0.9,0.1], [0.1,0.9] were considered. Mono-exponential dose-rate was assumed with effective decay rates ranging between 0.001 and 5 h^{-1} (i.e. $0.13 < T_{1/2} < 693$ h). Effective Lea-Catchised factors (G_{eff}) and Relative Effectiveness (RE_{eff}), explicitly accounting for the bi-exponential repair rates, were calculated. These were then compared to G_{mean} and RE_{mean} factors calculated using a mean repair rate for each pair of partition coefficients; the mean repair rate representing the global

repair rate used when a mono-exponential repair rate kinetic is assumed. Comparison was carried out by calculating the percentage difference between G_{eff} and G_{mean} and between RE_{eff} and RE_{mean}. RESULTS: The mean repair constants ranged between 0.17 and 1.18 h, depending on the partition coefficients. When the percentage differences were considered, these were equivalent for the Lea-Catcheside factors and the Relative Effectiveness and depended only on the repair rates, their partition coefficients and the effective half-lives: for all the partition coefficients, a percentage difference greater than 50% was observed for effective half-lives greater than 5 h. As a function of the effective decay rate, the lowest percentage difference was observed when the fast repair constant was dominant (partition coefficient [0.9, 0.1]). CONCLUSIONS: Under the assumptions of this study, the mean value of the individual repair constants of each sub-lethal lesions repair mechanism led to an underestimation of the RE, and therefore of the BED, up to 50% for clinically relevant effective half-lives ($T_{1/2}$ > 5 h).

OP279

Terbium-161 a Promising Radionuclide for the Irradiation of Tumor Cells and Micrometastases: Monte Carlo Dose Assessment using CELLDOSE

E. Hindie[1], M. A. Quinto[2], P. Zanotti-Fregonara[1], C. Morgat[1], C. Champion[2]; [1]CHU Bordeaux - University of Bordeaux - UMR 5287, Bordeaux, FRANCE, [2]Université de Bordeaux, CNRS/IN2P3, Centre d'Etudes Nucléaires de Bordeaux Gradignan (CENBG), Gradignan, FRANCE.

AIM: Radiopharmaceutical therapy, traditionally limited to the treatment of advanced metastatic disease, is now being considered in earlier settings to destroy minimal residual disease or occult micrometastases. The current study compares the effectiveness of ^{161}Tb, ^{177}Lu and ^{111}In to irradiate micrometastases. ^{161}Tb and ^{177}Lu associate a medium-energy β^- emission with various conversion and Auger electrons. They also have a small photon component which allows imaging. By contrast, ^{111}In is a γ-isotope for imaging that emits conversion and Auger electrons potentially helpful for therapy. METHODS: Electron dose was assessed in spheres of various sizes (from a 10-mm metastasis to a 10-μm single cell) with the Monte Carlo code CELLDOSE. The spheres were uniformly labeled with ^{161}Tb, ^{177}Lu or ^{111}In. Doses were compared for a fixed amount of energy released per unit volume (1 MeV per μm^3). The dose contribution from photons was neglected. RESULTS: In a 10-mm metastasis, the three isotopes exhibited equivalent dose deposit after normalization (1 MeV released per μm^3). This dose was 154 Gy for ^{161}Tb, 152 Gy for ^{177}Lu and 155 Gy for ^{111}In. However, for smaller micrometastases (<500μm), ^{161}Tb and ^{111}In were more effective than ^{177}Lu. For instance, in a 50-μm micrometastasis, the dose was 31 Gy for both ^{161}Tb and ^{111}In *vs*. 13.6 Gy for ^{177}Lu. In this 50-μm metastasis, conversion and Auger electrons were responsible for 75% of the dose from ^{161}Tb and for 20% of the dose from ^{177}Lu. A specific advantage of ^{111}In emerged only for single cells. In a cell of 10-μm diameter, doses from ^{111}In, ^{161}Tb and ^{177}Lu were 20.7 Gy, 11.5 Gy and 3.5 Gy, respectively. CONCLUSION: Choosing the appropriate isotope is fundamental to achieve an effective irradiation of micrometastases. Our study shows a selective advantage of ^{161}Tb over ^{177}Lu, especially for metastases <500μm, resulting from an emission spectrum rich in low-energy conversion and Auger electrons. ^{111}In appears advantageous for killing single-cells, but has the drawback of having a larger fraction of photon emission compared to ^{161}Tb.

OP280

Alpha radioimmunotherapy using 213Bi-anti MISRII mAb in ovarian cancer

R. LADJOHOUNLOU, Jr.[1,2,3], A. PICHARD[1,2,3], V. BOUDOUSQ[1,2,3], N. CHOUIN[4], F. BRUCHERTSEIFER[5], A. MORGENSTERN[5], I. Navarro-Teulon[1,2,3], J. Pouget[1,2,3]; [1]Inserm U1194, MONTPELLIER, FRANCE, [2]IRCM, Institut de Recherche en Cancérologie de Montpellier, Montpellier, FRANCE, [3]Université de Montpellier, Montpellier, F-34090,, Montpellier, FRANCE, [4]AMAROC, ONIRIS, NANTES, FRANCE, [5]European Commission, Joint Research Centre, Institute for Transuranium Elements, Karlsruhe, GERMANY.

Hypothesis: We assessed in vitro the therapeutic efficacy of the newly developed anti-MISRII mAbs (16F12 and 12G4) labeled with 213Bi in the therapy of ovarian cancer. In vivo, we explored their potential use during brief intraperitoneal radioimmunoptherapy (BIP-RIT). Methods: In vitro, clonogenic survival of SK-OV-3 cells expressing MISRII receptor were evaluated. Briefly, SK-OV-3 cells (donor cells) were incubated for 90 min with increasing activities (0-0.5MBq/mL) of anti MISRII 213Bi-16F12, 213Bi-12G4 mAbs or irrelevant 213Bi-Rituximab. We used the standard medium transfer protocol between donor cells and recipient cells (grown in non-radioactive medium previously incubated for 2h with donor cells) to evaluate bystander cytotoxic effects.

Uptake of radioactivity per cell together with appropriate cellular S-values were determined for absorbed dose assessment. Radiation-induced biological effects were measured in both donor and recipient cells as the yield of DNA double strand breaks (DSBs) through immunofluorescent detection of gamma-H2AX and 53BP1. In vivo we assessed in nude mice bearing intraperitoneal 2-3 mm SK-OV-3 MSIRII tumors nodules the biodistribution of radiolabeled antibodies (IP-RIT, 0-2.96MBq; 37MBq/mg) or BIP-RIT (5.5-12.9MBq; 37MBq/mg). BIP-RIT consisted of intraperitoneal injection of radiolabeled mAbs followed by washing of the peritoneal xenograft cavity with saline solution. After, the biodistribution of radiolabeled antibodies was investigated after IP and BIP-RIT. Results: In vitro we showed the strong efficacy of 213Bi-12G4 and 213Bi-16F12 mAbs. Bystander cytotoxicity was measured in all recipient cells for the three radiolabeled mAbs. In agreement with DNA DSBs formation, uptake of radioactivity by donor cells was shown to be higher for 213Bi-16F12 than for 213Bi-12G4. DNA DSBs yield was lower in recipient cells and preliminary results indicate that their complexity might be lower than the one measured in donor cells. In vivo, maximum tolerated activity of 213Bi-16F12 was about 2.9MBq and 12.9MBq after IP-RIT and BIP-RIT, respectively. Moderate hematological toxicity was observed in groups treated with the highest amount of activity. Biodistribution studies indicated that the tumor-blood uptake ratio was 1.4 and 6.3 one hour after IP and BIP-RIT, respectively. This ratio was decreased to 0.2 and 3.7, three hours post treatment, respectively. Therapeutic efficacy of 213Bi-12G4 and 213Bi-16F12 mAbs after IP-RIT and BIP-RIT is ongoing. Conclusions: In vitro, we showed the strong therapeutic efficacy of anti-MISRII 213Bi-16F12 mAb against ovarian cancer cells. We also showed that bystander effects were involved. In vivo, the feasibility of BIP-RIT using high activities of 213Bi-mAbs was demonstrated. We are now assessing its therapeutic efficacy using 213Bi-16F12.

OP281

Monte Carlo evaluation of Auger-electron emitting radionuclides in 3-D cellular models

N. Falzone[1,2], S. Able[1], S. Terry[1], J. M. Fernández-Varea[3], K. A. Vallis[1]; [1]University of Oxford, Oxford, UNITED KINGDOM, [2]Tshwane University of Technology, Department of Biomedical Science, Pretoria, SOUTH AFRICA, [3]Universitat de Barcelona, Facultat de Física (ECM and ICC), Barcelona, SPAIN.

Aim Auger-electron emitting radionuclides are ideal molecularly targeted radiotherapeutic (mTRT) agents when treating disseminated cancer cells and micro-metastasis. In the present study we evaluate the spatial distribution as well as clonogenic survival (SF) of two mTRT strategies in an in-vitro based 3-D tumour spheroid model; ^{111}In-DTPA-hEGF (a peptide targeting the epidermal growth factor-EGF) and ^{111}In-Trastuzumab (an antibody directed against the human epidermal growth factor receptor-2, HER2/neu). This information is then used to validate Monte Carlo (MC) simulations of a close packed 3-D cellular model in predicting tumour control probability (TCP). Materials and Methods Spheroids were formed from three tumour cell lines, MDA-MB-468 and MDA-MB-231/H2N breast cancer and SQ20B head/neck cancer cells, using a hanging droplet method. Spheroids were treated with ^{111}In-DTPA-hEGF (8 MBq/μg, 40 nM), and ^{111}In-Trastuzumab (6 MBq/μg; 10 nM) and evaluated 1 h and 24 h after treatment. SF was determined using a clonogenic assay and distribution was evaluated by cellular fractionation and micro-autoradiographic (MAR) staining of spheroid sections. The 3-D spheroid models were generated by a closed packed algorithm and MC software, PENELOPE was used to model radiation transport. Results Clonogenic survival correlated with radionuclide penetration, with the smallest SF noted in cell lines expressing the highest number of receptors; for EGFR targeting with ^{111}In-DTPA-EGF, the least survival was noted in MDA-MB-468 spheroids, while the lowest SF was noted in MDA-MB-231/H2N spheroids treated with ^{111}In-Trastuzumab. SQ20B form very tightly packed spheroids and although expressing a high number of EGFR, it showed little radionuclide penetration and corresponding greater survival. MAR staining showed two distinct spatial distribution patterns, i.e. outer rim of activity (1 h post treatment) or uniform distribution (24 h post treatment). TCP depended strongly on spatial distribution of the radionuclides, with uniformly distributed radionuclides achieving TCP1. Conclusion Tumour spheroids offer a viable model for investigating the penetration and spatial distribution of radiolabelled probes in tumour cells. Data was employed to inform mathematical modelling, in order to be able to use in silico methods to simulate drug distribution in tumour cells.

OP282

Potential radioprotectors and radiosensitizers in neuroendocrine tumor cells

S. Exner[1], S. Poenick[1], V. Prasad[2], **C. Grötzinger**[1]; [1]Charité - Universitätsmedizin Berlin, Gastroenterology, Berlin, GERMANY, [2]Charité - Universitätsmedizin Berlin, Nuclear Medicine, Berlin, GERMANY.

Aim: Neuroendocrine tumors (NETs) express somatostatin receptors that are currently utilized for diagnostic and therapeutic approaches. For peptide receptor radionuclide therapy (PRRT), somatostatin analogs like octreotide, are coupled to radionuclids like yttrium 90 or lutetium 177,

which after injection are bound and taken up specifically by NETs. PRRT can deliver radiation doses of up to 250 Gy to the tumors. Nevertheless, complete remission is extremely rare, compared to similar radiotherapies for thyroid cancer and non-Hodgkin lymphoma. One hypothesis potentially explaining the discrepancies between expected result and observed outcome of PRRT might be that somatostatin analogs induce a G1 arrest in NET cells, thereby making them radioresistant. Materials and Methods: To investigate this, NET cell lines were incubated with or without agonists and exposed to different radiation doses from a 137Cs source between 0 and 50 Gy. Cells were harvested at distinct timepoints, stained with propidium iodine and the cell cycle distribution was assessed by FACS analysis. Results: Initially, the somatostatin receptor expression (SSTR1-5) of five neuroendocrine tumour cell lines (BON, H727, QGP-1, LCC18, UMC11) was analyzed by quantitative real time PCR to assess the cell specific expression patterns of the different receptor subtypes. In radiation experiments all of five tested NET cell lines showed a radiation-induced decline in G1 cells as well as a G2/M arrest. Also, the percentage of apoptotic cells in sub-G1 phase increased time- and dose-dependently. Pretreatment with a potential G1 inhibitor resulted not only in an expected G1 arrest but also in a decrease of radiation-induced G2/M arrest. Moreover, a reduction of cells in sub-G1 was observed in two of five cell lines. In contrast, the combination of octreotide treatment with radiation showed no difference compared to radiation alone, not supporting the initial hypothesis. Conclusion: Further experiments are needed to better understand the influence of somatostatin agonists and other intrinsic or extrinsic factors on neuroendocrine tumor cells to pave the way for a significant increase in the overall therapeutic efficacy of PRRT.

Pharmacokinetic analysis of [11C]PBR28 in the rat model of herpes encephalitis: comparison with (R)-[11C]PK11195 for pre-clinical imaging

P. Kopschina Feltes[1], A. Parente[1], D. Vállez Garcia[1], J. W. A. Sijbesma[1], C. M. Moriguchi Jeckel[2], R. A. J. O. Dierckx[1], E. F. J. de Vries[1], J. Doorduin[1]; [1]University of Groningen, Groningen, NETHERLANDS, [2]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, BRAZIL.

Aim: [^{11}C]PBR28 is a second generation translocator protein (TSPO) ligand with supposedly better imaging characteristics than the most commonly used tracer [^{11}C]PK11195. Surprisingly, only limited studies have evaluated the pharmacokinetic and binding profile of [^{11}C]PBR28 in neuroinflammatory models in rodents. For this reason, [^{11}C]PBR28 was evaluated and compared to [^{11}C]PK11195 for the detection and quantification of neuroinflammation for pre-clinical research. Materials and methods: Herpes simplex encephalitis (HSE) was induced in male Wistar rats by intranasal inoculation of the herpes simplex type-1 virus, resulting in neuroinflammation. At 6-7 days post inoculation, 60-min dynamic [^{11}C]PBR28 or [^{11}C]PK11195 PET scans were performed. During the scans arterial blood samples were taken to generate blood and metabolite-corrected plasma input curves for pharmacokinetic modeling. Differences between control and HSE rats were assessed by voxel-based analysis, using standardized uptake values, and volume-of-interest analysis, using the reversible two-tissue compartment model to determine the binding potential (BP_{ND}). Results: Voxel-based analysis showed that [^{11}C]PBR28 was able to detect overexpression of TSPO in brain areas that are known to be affected in the HSE rat model. [^{11}C]PBR28 had a faster metabolism than [^{11}C]PK11195, with 50% of metabolites in plasma present at 5 min and 21 min, respectively. [^{11}C]PBR28 demonstrated a higher sensitivity than [^{11}C]PK11195 in the detection of neuroinflammation. The BP_{ND} of [^{11}C]PBR28 was significantly higher ($p<0.05$) in the medulla (150%), pons (121%), midbrain (94%), thalamus (76%), hippocampus (65%), hypothalamus (44%) and cerebellum (37%) of HSE rats when compared to control rats, while a higher BP_{ND} of [^{11}C]PK11195 was only found in the medulla (59%). Comparison of BP_{ND} between control groups showed no statistical difference, suggesting that non-specific binding of both tracers is similar. Conclusion: [^{11}C]PBR28 performed better than [^{11}C]PK11195 in the detection of TSPO overexpression in the HSE rat model, as the BP_{ND} was found to be increased in more brain regions. The results of this study suggest that [^{11}C]PBR28 is a better tool for pre-clinical research of neuroinflammation.

OP284

Radiosynthesis and fundamental evaluation of (R)-[11C] emopamil as a novel tracer for imaging enhanced P-glycoprotein function in the brain

J. Toyohara[1], M. Okamoto[1,2], H. Aramaki[2], Y. Zaitsu[2], I. Shimizu[2], S. Hosokawa[2], K. Ishiwata[1]; [1]Tokyo Metropolitan Institute of Gerontology, Tokyo, JAPAN, [2]Waseda University, Tokyo, JAPAN.

Aim: A number of substrate for P-glycoprotein (P-gp), such as [11C]verapamil ([11C]VER), was developed for imaging P-gp function with positron emission tomography (PET). These substrates can measure decreased function of P-gp as an increased uptake of tissue radioactivity. However, it would likely not be able to measure enhanced P-gp function, because base-line tissue radioactivity is already at most immeasurable. Emopamil (EMP) is a calcium channel blocker of the phenylalkylamine class, having high blood-brain barrier permeability and weak substrate properties for P-gp. These properties would be suitable for measuring enhanced P-gp function in the brain. The purpose of this study is to synthesize (R)- and (S)-[11C]EMP and to characterize their properties as a P-gp tracer. Materials and Methods: The EMP includes a chiral quaternary carbon centre, and a previous research has indicated that the optical isomers differ significantly in their biological effects. Therefore, we first synthesized (R)- and (S)-[11C]EMP and compared their biodistribution, peripheral metabolism, and effects of P-gp inhibitor cyclosporine A (CysA). Then, we compared the brain pharmacokinetics of (R)-[11C]EMP and (R)-[11C]VER in base line and CysA pre-treatment with small animal PET. Results and conclusion: (R)- and (S)-[11C]EMP were synthesized from (R)- and (S)-noremopamil, respectively, by methylation with [11C]methyl triflate in the presence of NaOH at room temperature. The yield of (R)- and (S)-[11C]EMP was approximately 30%. The specific activity of (R)- and (S)-[11C]EMP was >74 GBq/μmol and radiochemical purity was >99%. The biodistribution of (R)- and (S)-[11C]EMP in ddY mice demonstrated a significantly higher uptake of (R)-[11C]EMP in the brain. The regional brain distribution of (R)- and (S)-[11C]EMP were homogeneous and no stereo-selective. (R)- and (S)-[11C]EMP were rapidly metabolized to hydrophilic metabolite. Unchanged form of (S)-[11C]EMP (39%) was significantly lower than that of (R)-[11C]EMP (46%) at 15 min after injection in plasma. In contrast, over 88% of radioactivity in the brain was intact and no stereo-selective. CysA pre-treatment increased brain activity approximately 3-fold, however, no stereo-selective. Since (R)-[11C]EMP was metabolized less than that of (S)-[11C]EMP, (R)-enantiomer was further evaluated with small animal PET. The base line area-under-the-curve (AUC) of brain radioactivity (0-60 min) of (R)-[11C]EMP was 2-fold higher than that of (R)-[11C]VER, but its AUC after CysA pre-treatment was comparable to that of CysA pre-treated (R)-[11C]VER. In conclusion, (R)-[11C]EMP can be used as a novel tracer for imaging P-gp function with a higher base line uptake than (R)-[11C]VER.

OP285

Discovery of a Fluorinated 4-Oxo-Quinoline Derivative as a Potential PET Radiotracer for Targeting CB2 Receptor

L. Mu[1], R. Slavik[2], A. Herde Müller[2], S. D. Krämer[2], M. Weber[3], R. Schibli[2], S. Ametamey[2]; [1]UniversitätsSpital Zürich, ZURICH, SWITZERLAND, [2]ETH Zurich, ZURICH, SWITZERLAND, [3]Kantonsspital St. Gallen, ZURICH, SWITZERLAND.

Objectives: The cannabinoid receptor type 2 (CB2) is part of the endocannabinoid system and has gained growing attention in recent years due to its important role in neuroinflammatory/neurodegenerative diseases [1, 2].The PET imaging of CB2 has so far been unsuccessful. Recently, we reported on a carbon-11 labeled 4-oxo-quinoline derivative, designated RS-016 [3], as a promising radiotracer for imaging CB2. In this report, three fluorinated analogues of RS-016 were designed, synthesized and evaluated for their utility as imaging agents for the CB2. Methods: Three fluorinated analogues of RS-016 namely RS-030, RS-122 and RS-126 were synthesized using a multi-step reaction sequence and their binding affinities towards CB2 were determined using [^{3}H]-CP-55, 940. The most potent compound, RS-126 ((N-(1-adamantyl)-1-(2-(2-fluoroethoxy)ethyl)-8-methoxy-4-oxo-1,4-dihydroquinoline-3-carboxamide), was radiolabeled with fluorine-18 and further evaluated in autoradiographic studies, biodistribution experiments and metabolic studies. Results: The syntheses of RS-030, RS-122 and RS-126 were accomplished in overall chemical yields of 30%, 16% and 6%, respectively and their binding affinities (Ki values) towards CB2 ranged from 72-1.2 nM. RS-126 exhibited the highest binding affinity and selectivity towards CB2. [^{18}F]RS-126 was obtained in ≥ 99% radiochemical purity with a specific radioactivity of 98 ± 44 GBq/μmol (n = 15) at the end of synthesis. The logD7.4 value was 1.99 and in vitro autoradiographic studies with CB2-positive rat spleen tissue revealed high and displaceable binding. [^{18}F]RS-126 was stable in vitro in rat and human plasma over 120 min, whereas 55% intact parent compound was found in vivo in rat blood plasma at 15 min p.i.. Biodistribution studies confirmed accumulation of [^{18}F]RS-126 in rat spleen with a specificity of 79% under blocking conditions. Conclusion: The fluorinated CB2 radioligand, [^{18}F]RS-126, demonstrated high specificity towards CB2 receptor in vitro and in vivo and is potentially a promising ligand for imaging CB2 receptor expression. OP286

PET imaging of P-glycoprotein function at the rodent BBB: Diurnal fluctuations and impact of sleep deprivation

H. Savolainen[1], P. Meerlo[1], A. van Waarde[1], P. Elsinga[1], A. D. Windhorst[2], N. Colabufo[3,4], G. Luurtsema[1]; [1]University of Groningen, University Medical Center Groningen, Groningen, NETHERLANDS, [2]VU University Medical Center, Amsterdam, NETHERLANDS, [3]Università degli Studi di Bari, Bari, ITALY, [4]Biofordrug, Bari, ITALY.

Aim: Blood-brain barrier (BBB) contributes to brain homeostasis by protecting the brain from harmful compounds. P-glycoprotein (P-gp) is one of the major efflux transporters at the BBB. P-gp function can be modulated by endogenous and exogenous factors. Yet, little is known about fluctuations in P-gp function across the sleep-wake cycle. Recent studies suggest that substances accumulating during wakefulness may be cleared from the brain during sleep, a process that is impaired after sleep deprivation [1]. Therefore our research questions were: Is P-gp function constant or does it fluctuate across the day? Is P-gp function stronger during sleep and is it negatively affected by sleep deprivation? Materials and methods: Four groups of male Sprague-Dawley rats (n=6-8) were scanned at different moments of the 12 h light - 12 h dark cycle to study diurnal variations: early light phase (ZT 3, group 1), late light phase (ZT 9, group 2), early dark phase (ZT 15, group 3) and late dark phase (ZT 21, group 4). In two additional groups (n=7), controls were allowed to sleep normally while the experimental animals were sleep-deprived for 10 h in a slowly rotating drum during the light phase, which represents the normal sleep period. All rats were scanned with a new P-gp substrate tracer, [^{18}F]MC225 ((5-(1-(2-fluoroethoxy))-[3-(6,7-dimethoxy-3,4-dihydro-1H-isoquinolin-2-yl)-propyl]-5,6,7,8-tetrahydronaphthalen). Arterial blood samples were drawn during a 60 min scan. Afterwards, rats were terminated and peripheral organs and brain regions were collected for biodistribution analysis. Results: Distribution volumes (V_T) were calculated by a one-tissue-compartment model fit using whole blood and metabolite-corrected plasma data as input function. In all brain regions, group 3 had 1.2-1.8 fold higher V_T than other groups. Groups 1, 2 and 4 showed no significant differences. In the biodistribution study, some peripheral organs (e.g. testes) showed similar diurnal variation. Distribution volumes in sleep-deprived animals and controls were not significantly different. Conclusion: P-gp function in rats displays a daily rhythm with reduced function at the beginning of the dark phase or active phase. This rhythm is not dependent on sleep since sleep deprivation had no effect. It may be that P-gp function is modulated by the endogenous circadian clock via other processes than sleep, such as rhythms in neurotransmitters or cytokines. OP287

Comparative Evaluation of Two PET Radioligands for PDE10A, [11C]T-773 and [18F]FM-T-773-d2 in Nonhuman Primates

A. Takano[1], V. Stepanov[1], R. Nakao[1], N. Amini[1], H. Kimura[2], C. Halldin[1]; [1]Karolinska Institutet, STOCKHOLM, SWEDEN, [2]Takeda Pharmaceutical Company, Limited., FUJISAWA, JAPAN.

Aim: Since PDE10A is distributed mainly in striatal regions, it may be involved in psychiatric and neurodegenerative diseases such as schizophrenia and Huntington's disease. Here we evaluated and compared two recently developed radioligands for PDE10A [1], [11C]T-773, [1-[2-fluoro-4-(tetrahydro-2H-pyran-4-yl)phenyl]-5-methoxy-3-(1-phenyl-1H-pyrazol-5-yl)pyridazin-4(1H)-one] and a fluoromethyl analog, [18F]FM-T-773-d2, in nonhuman primates. Materials and methods: PET measurements (123 min) were performed four times for each PET radioligand using six female rhesus monkeys. Two monkeys had both radioligands and other four had one radioligand. Arterial blood sampling was performed to obtain the plasma input function. Protein binding was measured, and radio-metabolite analysis was performed for each PET measurement. The putamen and caudate as the target regions, and the cerebellum as a reference region, were delineated on coregistered PET/MRI. Total distribution volume (VT) was calculated by a two-tissue-compartment model (2TC). Binding potential (BPND) was calculated as a ratio of the VT between the target region and the reference region minus one. BPND was also calculated with simplified reference tissue model (SRTM). The stability of the outcome measures was investigated using the truncated PET data. Results: The whole brain uptake at peak was higher with [18F]FM-T-773-d2 than with [11C]T-773 (4.5%ID vs 3.4%ID). Average fractions of the parent compounds at 30 min were 57.3 ± 6.1% with [11C]T-773 and 63.7 ± 1.6% with [18F]FM-T-773-d2. No radio-metabolites more lipophilic than the parent compounds were detected. Protein binding was higher with [18F]FM-T-773-d2 than with [11C]T-773 (78.9 ± 3.1% and 56.7 ± 7.3%). VT of the cerebellum and putamen was 3.9 ± 0.5 and 11.9 ± 3.3 for [11C]T-773 and 4.8 ± 1.0 and 11.1 ± 0.8 for [18F]FM-T-773-d2, respectively. The BPND of the putamen obtained with 2TC and SRTM was 2.0 ± 0.4 and 1.9 ± 0.4 for [11C]T-773, and 1.4 ± 0.3 and 1.3 ± 0.3 for [18F]FM-T-773-d2. The duration of PET measurements was shortened stably to 39 min for [11C]T-773 and 33 min for [18F]FM-T-773-d2 for VT obtained with 2TC while it was shortened stably to 63 min for [11C]T-773 and 75 min for [18F]FM-T-773-d2 for BPND obtained with SRTM. Conclusion: Both [11C]T-773 and [18F]FM-T-773-d2 have good characteristics as PET radioligands for PDE10A. Although the whole brain uptake at peak was higher for [18F]FM-T-773-d2, BPND was higher for

[11C]T-773. The duration of PET measurement can be shortened to 39 min for both radioligands if the VT of the striatal regions obtained with 2TC is the outcome measure.

OP288

Quantification of Available NMDA (GluN) Receptor NTD Drug Binding Sites with the GluN2B-targeting PET Tracer [^{11}C]NB1

S. D. Krämer[1], T. Betzel[1], L. Mu[2], B. Tewes[3], B. Frehland[3], D. Schepmann[3], R. Schibli[1], B. Wünsch[3], S. M. Ametamey[1]; [1]ETH, Zurich, SWITZERLAND, [2]University Hospital Zurich, Zurich, SWITZERLAND, [3]Westfälische Wilhelms-Universität, Münster, GERMANY.

Aim: NMDA receptors (GluN) are key regulators of CNS plasticity and higher cognitive functions. We aimed at evaluating the potential of our novel GluN2B-targeting PET tracer [^{11}C]NB1 (7-[^{11}C]methoxy-3-(4-phenylbutyl)-2,3,4,5-tetrahydro-1H-benzo[d]azepin-1-ol) for quantitative PET and receptor occupancy studies. [^{11}C]NB1 is structurally related to drug candidates, such as ifenprodil, eliprodil and Ro-25-6981 that selectively bind to the GluN2 N-terminal domain (NTD).Materials and Methods: [^{11}C]NB1 was synthesized from its phenolic precursor by [^{11}C]methylation with [^{11}C]CH3I. Time-activity curves (TAC) for rat brain regions were recorded by PET after intravenous injection of 20 to 67 MBq [^{11}C]NB1. The blood TAC was simultaneously measured from a minimally invasive arterio-venous shunt. Data were fit to compartment models and input-function independent quantification methods were evaluated. To investigate the influence of cerebral glutamate on [^{11}C]NB1 PET, ketamine (25 mg/kg) was injected intraperitoneally 15-20 min before tracer injection. Receptor occupancy by eliprodil was characterized after intravenous injection of various doses of eliprodil 1 minute before the tracer (n=14).Results:For experiments with blood TAC recording (n=6; 1 blood TAC failed), [^{11}C]NB1 specific activity was 254-368 GBq/μmol (0.4-0.8 ng/kg injected dose). Data followed a 2-tissue compartment model with scan-time independent VT from 10 min onwards. Extraction from plasma to brain was close to 100%. At distribution equilibrium, tracer concentration in the first, non-specific compartment, was similar to the plasma concentration, resulting in VND ~1. Under baseline conditions (n=3), average VT was between ≤ 4.8 for olfactory cortex and cerebellum grey matter and ≥ 6.0 for midbrain and thalamus. The integrated standardized uptake value from 0 to 60 min (SUV0-60min) was evaluated for quantification in the absence of an input function. The comparison with VT revealed a Pearson's r for the 5 animals and 13 brain regions each, of 0.840. VT values after ketamine challenge (n=2) were similar to baseline values and values for SUV0-60min were not significantly affected (n=3). Whole brain SUV0-60min after eliprodil injection followed a saturation function. The fit dose at 50% receptor occupancy was 1.5 μg/kg (4.2 nmol/kg). Maximal blocking by an excess of eliprodil, NB1 and Ro-25-6981 was 47% (fit), 46% (n=1) and 55% (n=1), respectively, in agreement with ex vivo biodistribution results.Conclusion: [^{11}C]NB1 allows to quantify the availability of GluN2B NTD binding sites in rat brain. Whole brain specific binding is ~47% of total binding. Quantification is possible with and without an input function. Receptor occupancy by GluN2B NTD-targeting drugs can be quantified with [^{11}C]NB1.

OP289

Autoradiography and microPET rodent evaluation of the [18F]MCL-524 - an 18F-labelled dopamine D2/D3 receptor agonist

V. Stepanov[1], J. Häggkvist[1], M. Svedberg[1], R. Krasikova[2], S. J. Finnema[1], A. W. Sromek[3], J. L. Neumeyer[3], C. Halldin[1]; [1]Karolinska Institutet, Stockholm, SWEDEN, [2]N.P. Bechtereva Institute of Human Brain, St.-Petersburg, RUSSIAN FEDERATION, [3]McLean Hospital/Harvard Medical School, Belmont, MA, UNITED STATES.

AIM: Carbon-11 labeled dopamine D_2/D_3 receptor agonist radioligands have been shown to be sensitive to amphetamine-induced elevations in extracellular dopamine concentration across species. Labeling with fluorine-18 further increases usefulness of such radioligands for long duration imaging scenarios. In view of this, a novel fluorine-18 radiolabeled dopamine D_2/D_3 receptor agonist - [^{18}F]MCL-524 - was recently developed and evaluated successfully in non-human primates (NHP) (Finnema *et al*., J Nucl Med. 2014, 55:1164-70). We here evaluated scope of usefulness of [^{18}F]MCL-524 for autoradiography, using post-mortem tissue, as well as its potential for rodent PET imaging. METHODS: [^{18}F]MCL-524 was synthesized as described previously (Finnema *at al*. 2014). For autoradiography evaluation, rat and mouse brain slices (coronal sections, 14 μm thick) were incubated with 0.02 and 0.2 MBq/ml of [^{18}F]MCL-524 for 55 minutes in the absence and presence of 10 μM butaclamol, washed and imaged on a Fujifilm BAS-5000. Rodent PET imaging was conducted using rats with Mediso nanoScan® PET/MRI and nanoScan® PET/CT cameras (imaging time of 63 minutes, average injection of 17±1 MBq [^{18}F]MCL-524). Striatal BP_{ND} values were estimated with SRTM, using cerebellum as a reference region. RESULTS: In autoradiography studies accumulation of [^{18}F]MCL-524 was observed in most regions of the brain, including cortex and striatum, with little to none of the binding being displaceable by butaclamol. The result is in-line with other attempts to use carbon-11/fluorine-18 labeled D_2/

D_3 receptor agonists for the purpose. In the rodent baseline PET studies, average striatal BP_{ND} values were low, 0.29±0.23 (n=3), and a large variability between individual animals was observed. Pre-treatment with 1mg/kg of raclopride decreased striatal BP_{ND} by ~70% (n=3). CONCLUSIONS: The low BP_{ND} and high variability in [^{18}F]MCL-524 binding across animals limits its usefulness as an imaging tool for small animal PET. Comparison of the NHP and rodent imaging results indicates that the kinetic behavior of dopamine D_2/D_3 receptor agonist ligands *in vivo* differs significantly across species. Great care should be taken when assessing PET radioligands suitability for dopamine D_2/D_3 receptor imaging using different species.

OP290

Comparative evaluation of (R)-[11C]verapamil and [11C]-N-desmethyl-loperamide to assess P-glycoprotein function at the mouse blood-brain barrier

T. Wanek[1], S. Mairinger[1], J. Stanek[1,2], M. Sauberer[1], T. Filip[1], A. Traxl[1], C. Kuntner[1], J. Pahnke[3], M. Müller[2], O. Langer[1,2]; [1]AIT Austrian Institute of Technology, Seibersdorf, AUSTRIA, [2]Medical University of Vienna, Vienna, AUSTRIA, [3]University of Oslo (UiO) and Oslo University Hospital (OUS), Oslo, NORWAY.

Aim: Brain distribution of many drugs can be restricted by efflux transport at the blood-brain barrier (BBB) mediated by the adenosine triphosphate-binding cassette transporter P-glycoprotein (Pgp). Pgp function has been shown to be altered in neurological diseases such as epilepsy and Alzheimer's disease. Positron emission tomography (PET) with the Pgp substrates (*R*)-[^{11}C]verapamil ([^{11}C]VPM) and [^{11}C]-*N*-desmethyl-loperamide ([^{11}C]dLop) has been used to assess Pgp function at the rodent and human blood-brain barrier (BBB). Aim of this study was to directly compare [^{11}C]VPM and [^{11}C]dLop for assessment of Pgp function at the mouse BBB. Material and Methods: Imaging experiments were performed in groups of isoflurane-anesthetized, female C57BL/6N mice and homo- and heterozygous Pgp-knockout mice which were pretreated 2 h prior start of PET with different doses of the Pgp inhibitor tariquidar or vehicle solution. Dynamic (0-60-min) PET scans were initiated at the start of injection of either [^{11}C]VPM or [^{11}C]dLop. Brain uptake of [^{11}C]VPM or [^{11}C]dLop, was expressed as the brain to plasma ratio of radioactivityin the last PET frame (50-60 min after injection). In separate groups of mice radiolabelled metabolites of both radiotracers were analyzed in plasma and brain by radio-TLC.ResultsFollowing injection, radioactivity in whole brain reached an approximately 3-4 times higher peak concentration for [^{11}C]VPM than for [^{11}C]dLop. [^{11}C]VPM washed out from brain whereas [^{11}C]dLop appeared to be trapped in brain tissue. In Pgp knockout mice, brain uptake of [^{11}C]VPM and [^{11}C]dLop was 3.9- and 2.8-fold higher, respectively, as compared with wild-type mice. In heterozygous mice, which have 50% lower Pgp expression levels at the BBB than wild-type mice, brain uptake of [^{11}C]VPM and [^{11}C]dLop was increased by only 1.5- and 1.1-fold, respectively, as compared with wild-type mice. Both radiotracers showed tariquidar dose dependent increases in brain distribution. Whereas brain distribution of [^{11}C]VPM reached in tariquidar-treated mice similar levels as in Pgp knockout mice, this was not the case for [^{11}C]dLop. For both radiotracers, radiolabelled metabolites were detected in plasma and brain with a higher percentage of radiolabelled metabolites for [^{11}C]dLop than for [^{11}C]VPM. Conclusion: Both [^{11}C]VPM and [^{11}C]dLop can be used to assess Pgp function at the mouse BBB. However, both radiotracers displayed limited sensitivity to assess small (<50%) variations of Pgp function at the mouse BBB, with [^{11}C]dLop being less sensitive than [^{11}C]VPM. Use of both radiotracers is compromised in mice by significant peripheral metabolism and brain uptake of radiolabelled metabolites.

Urology, Aarhus University Hospital, Aarhus N, DENMARK.

Objective: Tumor Blood Flow (TBF) is an indicator of tumor aggressiveness in a variety of cancers and may aid in identifying

aggressive prostate cancer and in monitoring treatment. The gold standard for measuring TBF is 15O-H2O PET combined with arterial blood sampling (BSIF). This is, however, logistically challenging and requires an on-site cyclotron. We investigated the accuracy of simplified TBF measurements using with image derived input functions (IDIF) with 15O-H2O and the more widely accessible tracer 82Rb. Method: 9 patients with prostate cancer were included. Dynamic PET scans of the heart (for IDIF extraction) and pelvis were performed with both 15O-H2O and 82Rb. During the 15O-H2O scans arterial blood sampling was performed. On the same day, T2w and DWI MRI were acquired. IDIFs were automatically extracted using cluster analysis. ROIs of tumor, peripheral zone and transition zone were drawn on MRI images coregistered to the PET series. TBF was calculated using BSIF or IDIF data from either the aorta, as obtained from the separate heart scan, or the iliac arteries. Results: Automatic extraction of IDIFs derived from the aorta/left ventricle (heart scans) and the iliac arteries (pelvis scans) was successful in all cases. Excellent correlations were found between TBF obtained using blood sampler input and each IDIF (TBF(heart IDIF)=1.11xTBF(BSIF)+0.004, R2=0.96 and TBF(Iliac IDIF)=5.23xTBF(BSIF)-0.16, R2=0.93) for the 15O-H2O scans. Correcting for the flow-dependent extraction of 82Rb using the Renkin-Crone model, a good correlation was found between 82Rb K1 and 15O-H2O TBF (R2=0.96). Furthermore, high correlation was found between 82Rb K1 and 82Rb SUV (SUV=7.82xK1(82Rb)+0.47, R2=0.83). In 5 patients, TBF was elevated relative to the peripheral zone. However, in 4 patients elevated blood flow was also seen in the transition zone, most likely due to benign prostatic hyperplasia. Conclusion: Both 15O-H2O and 82Rb can be used for quantitative imaging of tumor blood flow in prostate cancer without catheter-based arterial blood sampling. Full pharmacokinetic analysis can be performed without the need for arterial blood sampling by using the automatically extracted IDIFs from either the iliac arteries or a separate scan of the heart. In the former case, a scanner dependent recovery factor is needed. Further simplification is possible by using SUV values obtained from static images.

Phase I Safety and Biodistribution Study of 124I-PEG-AVP0458 Diabody in Patients with TAG-72 Positive Ovarian and Prostate Cancer

A. M. Scott[1,2], T. Akhurst[3], F. Lee[2], M. Ciprotti[1], I. Davis[1], A. Weickhardt[1], H. Gan[1], P. Kocovski[2], N. Guo[2], D. Murphy[3], R. Hicks[3], S. Lee[1], G. O'Keefe[1], S. Gong[1], P. Hudson[4]; [1]Austin Health, Melbourne, AUSTRALIA, [2]Olivia Newton-John Cancer Research Institute, Melbourne, AUSTRALIA, [3]Peter MacCallum Cancer Centre, Melbourne, AUSTRALIA, [4]Avipep Pty Ltd, Melbourne, AUSTRALIA.

Background: The development of antibody therapeutics for imaging and payload delivery is complex, and intact IgG have long half-lives that impact on tumor:blood ratios and tumor penetrance. Smaller molecular weight antibody constructs (eg diabodies) have been developed for improved penetrance into tumor, faster blood clearance, and enhanced tumor: normal tissue uptake, however renal uptake may impact on imaging and therapeutic effects. Through a novel pegylation strategy, a diabody to TAG-72 (AVP0458) has been generated, and produced under cGMP for a first-in-human clinical trial.Materials and Methods: We have conducted a Phase I, open label, first-in-human trial of PEG-AVP0458. The primary study objective was the safety of single dose of I-124 PEG-AVP0458 in patients (pts) with TAG-72 +ve relapsed / metastatic prostate or ovarian cancer. Secondary study objectives were evaluation of the biodistribution, tumor targeting, pharmacokinetics (PK) and immunogenicity of I-124 PEG-AVP0458. Pts were infused with I-124 PEG-AVP0458 (3-5mCi) at one of two dose levels (1mg/m2 and 10mg/m2), and imaged sequentially over a one week period. Safety, PK, and immunogenicity were assessed up to 30 days post infusion.Results: Six pts (1F:5M; age range 62-85yrs; 1 ovarian cancer, 5 prostate cancer) were entered into the study, 3 at each dose level. I-124 PEG-AVP0458 was well tolerated, with no infusion-related adverse events, and no serious adverse events observed. There was consistent biodistribution on PET imaging of I-124 PEGAVP0458, with no normal tissue uptake. High tumor uptake was evident in metastatic disease in liver and lymph nodes, with lesion uptake seen within 1-2 days post infusion. PK analysis showed a T½β of 46.8 ± 12.4 hrs. There was no impact of protein dose on biodistribution, tumor uptake or PK. No immunogenicity to PEG-AVP0458 was evident.Conclusions: I-124 PEG-AVP0458 is safe, and demonstrates excellent, rapid targeting of tumor in-vivo, with no normal organ uptake, and high tumor: blood ratios. This data demonstrates the feasibility of using pegylated diabodies for imaging and for payload delivery of radionuclides (RIT) or cytotoxic drugs (ADC) in cancer patients.ANZCTR Number: ACTRN12612000802808

Parasympathetic Imaging of Prostate Cancer using 11C-Donepezil PET.

M. Stokholm[1], S. Høyer[2], S. Jakobsen[1], D. Bender[1], M. Borre[3], J. Frøkiær[1], **P. Borghammer**[1]; [1]Department of Nuclear Medicine & PET Centre, Aarhus University Hospital, Aarhus, DENMARK, [2]Department of Pathology, Aarhus University Hospital, Aarhus, DENMARK, [3]Department of Urology, Aarhus University Hospital, Aarhus, DENMARK.

Background It was recently shown that high-grade prostate

cancer (PC) is characterized by parasympathetic neuroneogenesis, which promotes cancer dissemination, and is associated with decreased survival. We have previously validated 11C-donepezil PET as a marker of parasympathetic innervation. 11C-donepezil PET could therefore have utility in risk-stratification of PC patients, and may facilitate targeted biopsies or focal therapyObjectivesTo investigate 11C-donepezil uptake in low- and high-grade PC as a marker of parasympathetic neuro-neogenesis.MethodsThe 11C-donepezil uptake in PC was investigated using autoradiography of prostatectomy tissue from 13 patients and correlated to Gleason scores (GS). In pilot PET-studies we aim to perform in vivo 11C-donepezil PET imaging in two groups of 12 PC patients with low- and high-risk PC based on biochemical and biopsy risk-stratification.ResultsIn prostatectomy tissue, 11C-donepzil exhibited increased uptake in high-grade PC compared to low-grade and benign hyperplasia. The mean uptake ranged from 56% (GS3+3) to 409% (GS4+4). Preliminary in vivo 11C-donepezil PET studies in five PC patients with low-grade PC (GS≤7) demonstrated only slight uptake in the prostate (SUVmax<4.6), whereas two patients with high-grade PC (GS≥8) showed high focal uptake in the prostate (SUVmax >7.5). Interestingly, high uptake was also seen in bone metastases (SUVmax 7-12) and enlarged pelvic lymph nodes (SUVmax 7-11) in two patients with disseminated PC.ConclusionsIn autoradiography studies, the uptake in tumor tissue of the cholinergic PET ligand 11C-donepezil correlated with GS. Preliminary PET studies suggest that 11C-donepezil may be able to predict the GS in vivo. Parasympathetic PET imaging may therefore have utility for targeted biopsies in PC patients, and may aid in selecting patients for radical prostatectomy.

Effect of androgen deprivation therapy on the results of PET/CT with [18F]fluciclovine in patients with prostate cancer

T. Bach-Gansmo[1], H. Sletten[2], M. C. Småstuen[2], A. M. Løndalen[1], T. V. Bogsrud[1]; [1]Oslo University Hospital, Oslo, NORWAY, [2]Oslo and Akershus University College, Oslo, NORWAY.

Purpose: Anti-androgenic hormonal treatment seems to reduce the sensitivity of 11C- and 18F-Choline PET (1). [18F]-fluciclovine (FACBC) is a new radiopharmaceutical for positron emission tomography (PET) of prostate cancer. We wanted to find out to which extent androgen deprivation therapy (ADT) would influence the sensitivity of FACBC PET in patients with metastatic disease. Methods: This was a retrospective register trial performed in 350 patients with prostate cancer examined with FACBC, of whom 76 received ADT. Informed consent was obtained from all patients. The sensitivity of FACBC PET/CT in patients on ADT was compared with the sensitivity for the total material, 350 patients with primary or recurrent prostate cancer with or without metastatic disease. Results: The number of PET positive cases in the total material was 59%. The sensitivity was 71%, higher but not statistically significant, in the subgroup receiving ADT, and this whether the PSA was stable/declining (65% positive PET) or rising (77% positive PET). Discussion/ Conclusion: Invitro studies have shown that anti-androgen treatment causes downregulation of the LAT3 receptor, which in turn is responsible for an upregulation of LAT1 and ASCT transporters (2), responsible for the uptake of amino acids such as fluciclovine. ADT does not render FACBC PET examinations negative, and as a result FACBC may be particularly useful in this patient group. Additionally FACBC may be less suitable for monitoring the response to ADT. References: 1.Giovacchini G, Picchio M, Coradeschi E, Scattoni V, et al. OP296

68Ga-DOTATATE compared with11C-Choline PET/CT in patients with hormone-resistant prostate cancer at biochemical relapse.

O. Alonso[1,2], G. Dos Santos[1,2], E. Savio[1], M. Garcia-Fontes[1], H. Engler[1]; [1]Uruguayan Centre of Molecular Imaging (CUDIM), Montevideo, URUGUAY, [2]Clinical Hospital, University of Uruguay, Montevideo, URUGUAY.

In hormone resistant prostate cancer (HRPC), neuroendocrine differentiation has been associated with up to 85% of patients. These cells express somatostatin receptors (SSTR) that can be targeted with 68Ga-DOTATATE. Therefore, we present the preliminary results of a prospective trial aiming to compare the diagnostic values of 68Ga-DOTATATE and 11C-Choline PET/CT in patients with HRPC at biochemical recurrence. The study involved 64 prostate cancer patients (median age: 65, range: 47-85 years) with PSA relapse under androgen deprivation therapy, with a median trigger PSA level of 4.25 ng/mL (range: 0.22-291 ng/mL). Within 1-2 weeks, a PET/CT study was performed with 68Ga-DOTATATE and 11C-

Choline with an approximately dose of 100 MBq and 400 MBq, respectively, using a 64-slice PET/CT with time-of-flight correction. Correlative imaging, histopathology and/or clinical follow-up (median follow-up time: 19 months, range: 9-31 months), were considered as reference standard. Both techniques showed positive local, regional lymph node and distant findings in 31 patients. Results were concordant in 57 cases (89%), with discordant findings observed in patients with bone (n=2) and regional lymph nodes lesions (n=5). On a per patient basis, sensitivity, specificity, positive and negative predictive values with their 95% confidence intervals were the same for both techniques: 0.82 (0.65-0.93), 0.90 (0.73-0.98), 0.90 (0.73-0.98) and 0.81 (0.65-0.93), respectively. Although a trend toward a lower sensitivity was observed for patients with lower PSA levels, the difference was not statistically significant: 0.63 vs. 0.89, P=0.13, same values for both tracers, for patients with PSA < 4.25 and ≥ 4.25 ng/mL, respectively. False-positive lesions (n=5) were found, for both tracers, in 3 patients and were located in the prostate bed (n=1) and regional lymph nodes (n=4), being 3 discordant. In all cases, pathology revealed non-specific inflammatory lesions. 68Ga-DOTATATE and 11C-Choline PET/CT seem to have complementary value for the evaluation of HRPC patients with biochemical relapse. Further studies are needed to confirm these findings.

OP297

Two-phase 68Ga-PSMA-HBED-PET/CT in patients with high-risk prostate carcinoma or PSA-relapse

C. Bouter, B. Meller, C. O. Ritter, J. Lotz, J. Meller, S. Hijazi, C. O. Sahlmann; UMG Göttingen, Göttingen, GERMANY.

Aim: Current preclinical studies show increasing uptake of Ga-68-PSMA over time indicating a better lesion/background ratio in Ga-68-PSMA-PET/CT. The aim of this study was the evaluation of the clinical value of two-phase Ga-68-PSMA PET/CT in patients with high risk prostate carcinomas (PC) or suspected recurrence of disease. Methods: A retrospective study of 35 PC patients (aged 48-76, median 71) that underwent two-phase Ga-68-PSMA-PET/CT was performed. Acquisition was done 1h and 3h after injection of 140-392 MBq (median 301 MBq) Ga-68-PSMA with 10-11 bed positions on a Philips Gemini TF16. Maximum standard uptake values (SUVmax) of lesions were measured in both scans and lesions were correlated with histology and / or diagnostic findings of other imaging modalities. Results: Primary tumor showed high SUVmax values 1h p.i. (range 4,3-64,4; median 10, 85) with significantly increased values after 3h p.i. (range 5,3-107,6; median 18,15). Histologically proven lymph node (LN) metastases also showed high SUVmax values 1h p.i. (range 2-37,3; median 9,8) rising up to 3h p.i. (range 3,7-52,7; median 15,2) whereas no correlation between size and SUVmax was detected. Radiologically proven bone metastasis also featured significantly higher SUVmax values in scans up to 3h p.i. (median 1h p.i.: 4,8; median 3h p.i. 7,15). However, benign LN showed lower SUVmax values 1h p.i. (range 0,8-2,5; median 1,4) with decreasing values 3h p.i. (range 0,7-1,5; median 1,05). Conclusions: Uptake of PC lesions in Ga-68-PSMA-PET/CT increases significantly over time in vivo. Two-phase Ga-68-PSMA-PET/CT may help to differentiate between benign lesions and PSMA-expressing PC-relapses or -metastases.

OP298

A Direct Comparison Study of Ga-68-NODAGA-MJ9 (MJ9, Bombesin) to F-18-FCH (FCH) in Recurrent Prostate Cancer

P. Mitsakis[1], T. Zilli[2], M. Kosinski[3], J. Delage[1], H. Maecke[4], R. Mansi[4], J. Bourhis[5], F. Buchegger[1], R. Miralbell[2,6], J. O. Prior[1]; [1]Department of Nuclear Medicine, Lausanne University Hospital, Lausanne, SWITZERLAND, [2]Department of Radiation Oncology, University Hospital of Geneva, Geneva, SWITZERLAND, [3]Institute of Radiation Physics, Lausanne, SWITZERLAND, [4]Department of Nuclear Medicine, University Hospital of Freiburg, Freiburg, GERMANY, [5]Department of Radiation Oncology, Lausanne University Hospital, Lausanne, SWITZERLAND, [6]Institut Oncològic Teknon, Barcelona, SPAIN.

Purpose: We aimed to compare the diagnostic accuracy of 68Ga-NODAGA-MJ9 (MJ9, a novel radiopharmaceutical targeting the gastrin releasing peptide receptor) PET/CT with 18F-FCH (FCH) in recurrent prostatic cancer (PC).Materials and Methods: MJ9 was radiolabelled with the eluate of a 68Ge→68Ga generator using an automatic processor unit (PharmTracer). FCH PET/CT was performed with 18F-labelled fluoromethycholine. We included 33 PC patients (age 68±6y [53-82y]) treated by prostatectomy (27/33=82%) or radiation therapy without prostatectomy (6/33=18%) with biochemical PC relapse (PSA 4.7 ±4.1ng/mL [range 0.3-18.1]) and mean Gleason score 7.2 ±0.9 [5-9]. They underwent within a 10-day period both 68Ga-NODAGA-MJ9 (200MBq) and 18F-FCH (200 MBq) PET/CT imaging at 70 min p.i. Lesions were classified of local, lymph node [LN] and osseous origins and corresponding SUVbw_max (SUV) was recorded in each lesions.Results: In total, 81 lesions (14 local, 39 LN, 24 bone) were detected in 29 patients using 68Ga-NODAGA-MJ9 or 18F-FCH. In 4 patients (4/33=12%)

no lesion was found with both tracers (n=4; PSA=1.2±1.0 [0.3-2.4]). Of the 77 remainder lesions, SUV was similar in local lesions (n=14; MJ9=6.2±3, FCH=5.9±3.2, p=0.8), while it was significantly higher for MJ9 in LN (n=39; MJ9=9.3±8.3; FCH=5.7±4.8; p=0.004) and significantly lower for MJ9 in bone lesions (n=24; MJ9=2.2±1.8; FCH=6.1±3.6; p<0.0001). As compared to FCH, MJ9 missed 18/24 (75%) lesions in bone, 7/39 (18%) lesions in LN, but detected 5/39 (13%) more lesions in LN. When excluding bone lesions, MJ9 had +46% higher SUV than FCH (n=53; MJ9=8.5±7.4; FCH=5.8±4.4; p=0.005).Conclusion: 68Ga-NODAGA-MJ9 uptake was greater than 18F-FCH PET/CT in local and lymph node lesions, while 18F-FCH seemed better for bone lesions in biochemical relapse of prostate cancer patients.

OP299

A Novel Gallium-68-Labelled GRP Receptor Antagonist, [68Ga]Sarabesin 3, for Prostate Cancer Imaging: First Results in Therapy Naïve Primary Patients

I. L. Bakker[1], A. C. Fröberg[1], M. Busstra[1], G. J. L. H. van Leenders[1], E. de Blois[1], I. Schoots[1], J. Veenland[1], T. Maina[2], W. M. van Weerden[1], B. Nock[2], M. de Jong[1]; [1]Erasmus MC, Rotterdam, NETHERLANDS, [2]National Center for Scientific Research "Demokritos", Athens, GREECE.

AIM: There is an unmet demand for more sensitive diagnostic tools in patients with prostate cancer (PC), to improve staging as well as tumour localisation in case of increased tumour markers after treatment. Gastrin releasing peptide receptors (GRPr), being overexpressed in PC but not in normal prostate tissue or benign hyperplasia, could provide an excellent target in PC. [68Ga]Sarabesin 3, a GRPr antagonist, was selected for clinical translation after promising preclinical results in mouse PC models, including high tumour uptake and favourable tumour-to-background ratios. The aim of this trial is to validate GRPr PET-CT imaging in patients with primary PC who are scheduled for surgery. MATERIALS AND METHODS: As yet, three patients with PC confined to the prostate have been included; patients were imaged over a period of 3.5 h after administration of [68Ga]Sarabesin 3 (147±14 MBq, 40±5 μg). PET-CT imaging included dynamic scanning, multiple local images, and two total-body scans. The bladder was continually flushed, enabling optimal imaging of the prostatic region. PET-CT images were matched with the most recent MR scans. Radiotracer stability, activity curves in blood and urine as well as gastrin levels were measured. After prostatectomy, the pathologist examined the tissue confirm tumour localisations and autoradiography was performed to confirm GRPr overexpression. RESULTS: [68Ga]Sarabesin 3 PET-CT-scans showed focal uptake in the prostate first at 45 min p.i.. At earlier time points blood pool activity was too high to distinguish from focal accumulation. In all patients increased uptake was seen corresponding to localisations of PC as determined by pathology. One patient had a tiny tumour, which could only be confirmed by a special biopsy procedure including 40 biopsies; PC was found in only one needle core. Still, persistent uptake was corresponding to this tiny lesion. In another patient the MR identified unilateral tumour presence, while histology confirmed results of the GRPr scan, showing tumour on both sides. The GRPr-expressing pancreas showed high physiological uptake. Diffuse and low uptake was seen in the whole gastrointestinal tract and lower oesophageal and rectal sphincters. The liver showed almost no activity. Serial images and urine specimens showed fast renal excretion. The compound was very stable in blood and urine. Apart from some discomfort by the flush catheter, patients did not report any side effects. CONCLUSION: These first findings suggest [68Ga]Sarabesin 3 PET-CT to have great potential as an imaging tool in patients therapy naïve primary suffering from PC.

Use of 18FDG-PET/CT to predict outcome in patient with locally advanced pancreatic cancer

L. Locantore[1], P. Mapelli[1], E. Incerti[1], P. Alongi[2], V. Gangemi[3], P. Passoni[4], N. Slim[4], N. Di Muzio[4], L. Gianolli[1], M. Picchio[1]; [1]Nuclear Medicine Department, IRCCS San Raffaele Scientific Institute, Milan, ITALY, [2]University of Milano-Bicocca, Milan, ITALY, [3]Nuclear Medicine Unit, Department of Biomedical Sciences and of Morphologic and Functional Images, University of Messina, Messina, ITALY, [4]Radiotherapy Department, IRCCS San Raffaele Scientific Institute, Milan, ITALY.

Aim. Despite the routinary use of chemotherapy (CH) in combination with radiotherapy, patients with locally advanced pancreatic cancer (LAPC) have a poor prognosis. Helical tomotherapy (HTT) is a promising option for local control, allowing a highly conformed radiation dose to the lesion, sparing non-target organs. We investigated if routinary use of 18FDG-PET/CT (PET) could predict progression free survival (PFS) in patients with LAPC. Materials and methods. Fifteen patients with a mean age of 63 years (range: 45-81 years) were enrolled and underwent to PET at basal time, after CH and HTT treatment, for a total of 45 scans. Results were interpreted in both a qualitative (visual examination) and semiquantitative way (maximum and delta standard uptake value - SUVmax and ΔSUV%). PET results were compared to clinical and

radiological follow-up data (12 months). PFS using Kaplan-Meier method and relative risk of progression (RRP) with Cox regression analysis were estimated for all patients. A ΔSUV cut-off of positivity for survival analysis was derived from ROC curve analysis. Results. PET was positive in all patients at basal time, in 10/15 after CH and in 11/15 after HTT. SUVmax ranged from 2.3-13.4 (mean: 7.0) at basal time, 1.5-14.8 (mean: 5.0) after CH and 1.8-17.3 (mean: 4.9) after HTT. ΔSUV values ranged from 31-88% (mean: 53%) after CH and 11-79% (mean: 50%) after HTT. Twelve months follow-up data showed stable disease in 8/15 and progression of disease in 7/15 patients. On the basis of ROC analysis results, a ΔSUV cut-off of threshold of 30% (ΔSUV30) was chosen. PFS rates over 1-year in the PET group with ΔSUV<30 after CH versus the PET group with ΔSUV>30 were 45% versus 53% (p= 0.360). PFS rates over 1-year in the PET group with ΔSUV<30 after HTT versus the PET group with ΔSUV>30 were 25% versus 75% (p= 0.075). Cox regression analysis showed a high RRP for PET group with ΔSUV<30 after HTT (HR 5.9; p= 0.064). Conversely, no significant results was found on risk analysis for PET group with ΔSUV<30 after CH. Conclusions. The routinary use of PET after combined treatment demonstrated a predictive role for therapy response assessment. ΔSUV% cut-off approach might provide efficient risk stratification after HTT. Our results suggest a high prognostic value of PET using a ΔSUV30 for HTT response assessment in prediction of RRP and PFS.

OP301

Predictive value of 18F-FDG PET/CT in patients after primary radio-chemotherapy of head and nack cancers.

I. SANDLER[1], P. Castellucci[1], R. Frakulli[2], U. Caliceti[3], G. M. Lima[1], J. J. Morigi[1], A. Bellusci[3], S. Cammelli[2], S. Fanti[1]; [1]Università di Bologna, Nuclear Medicine Unit, S.Orsola-Malpighi Hospital, Bologna, ITALY, [2]Università di Bologna, Radiotherapy Unit, S. Orsola-Malpighi Hospital, Bologna, ITALY, [3]Università di Bologna, Head and Neck Unit , S. Orsola-Malpighi Hospital, Bologna, ITALY.

Aims: The purpose of this retrospective study is to assess the prognostic value of ^{18}F-FDG PET/CT performed as treatment response evaluation after primary concomitant radio-chemotherapy (RT-CT) for locoregional advanced Head and Neck squamous cell carcinoma (HNSCC). Methods: 151 patients, (108 males and 43 females, mean age 59 yo) underwent ^{18}F-FDG PET/CT after RT-CT for HNSCC, between 2006-2013 to assess response treatment. The sites of HNSCC were oral cavity (10%), nasopharynx (14%), oropharynx (53%), hypopharynx (7%), larynx (7%), salivary glands (5%) and paranasal sinuses (4%). ^{18}F-FDG PET/CT has been preformed from 6 to 36 weeks (median 21 weeks) after the end of RT-CT. Patients were divided in three groups: ^{18}F-FDG PET/CT performed from 6 to 14 weeks after the end of RT-CT (group-A; 31 patients), from 15 to 23 weeks (group-B; 89 patients) and from 24-36 weeks (group-C; 31 patient). ^{18}F-FDG PET/CT scans were performed according to standard procedure then were visually analyzed by two expert physicians and categorized as negative ("score-1"), doubt negative ("score-2"), doubt positive ("score-3") and positive ("score-4"). Patients were followed-up, based on clinic and radiological and/or histological findings, up to 60 months and for at least 12 months after end of therapy (median 38 months). ^{18}F-FDG PET/CT results were classified as true positive (TP), true negative (TN), false positive (FP) and false negative (FN). Results: - Group A: showed "score-1" 14 patients, "score-4" 12 patients, therefore ^{18}F-FDG PET/CT sensitivity 69%, specificity 77%, VPP 75%, VPN 71%, accuracy 0.73. This group showed five doubt scans (16%) as "score-2": two negatives and three positives. No "score-3" - Group B: showed "score-1" 55 patients, "score-4" 27 patients, therefore ^{18}F-FDG PET/CT sensitivity 84%, specificity 98%, VPP 96%, VPN 91%, accuracy 0.93. This group showed total seven (8%) doubt scans: three scans (3,5%) as "score-2" (one negative and two positives) and four scans (4, 5%) as "score-3" (two negatives and two positives). - Group C: showed "score-1" 24 patients, "score-4" 6 patients, therefore ^{18}F-FDG PET/CT sensitivity 100%, specificity 100%, VPP 100%, VPN 100%, accuracy 1. This group showed only one doubt scan (3%) as "score-2" that was find out to be negative. Conclusions: According to our data, PET/CT with ^{18}F-FDG showed an excellent prognostic value of treatment response to primary concomitant RT-CT if performed at least after fourteen weeks following the end of RT-CT. We observed also that the numbers of "doubt scans" significantly decrease after fourteen weeks following the end of RT-CT.

OP302

Predictive value of 18F-FDG PET/CT in restaging patients affected by ovarian cancer: a multicenter study.

F. Caobelli[1], P. Alongi[2], L. Evangelista[3], M. Rensi[4], A. Castello[5], I. Laghai[5], C. E. Popescu[6], C. Dolci[6], S. Seghezzi[7], Young AIMN Working Group; [1]Hannover Medical School, Hannover, GERMANY, [2]University of Milano Bicocca,, Milan, ITALY, [3]Istituto Oncologico Veneto, Padua, ITALY, [4]Hospital of Udine, Udine, ITALY, [5]University of Florence, Florence, ITALY, [6]Niguarda Hospital, Milan, ITALY, [7]Hospital of Treviglio, Treviglio (BG), ITALY.

Purpose: ovarian cancer is the eighth most common malignancy among women and has a high mortality rate. Prognostic factors able to drive an effective therapy are essential. 18F-FDG PET/CT has been investigated in patients with epithelial ovarian cancer and showed promise in diagnosing, staging,

detecting recurrent lesions and monitoring treatment response. Conversely, its prognostic role remains unclear. We aimed at assessing the prognostic value of 18F-FDG PET/CT performed in the restaging process in a multicentre study. Methods: We evaluated 168 patients affected by ovarian carcinoma, who underwent a restaging 18F-FDG PET/CT. The presence of local recurrences, nodal involvement and distant metastasis was recorded as well as lesion dimensions, maximum and mean standardized uptake values (SUVmax and SUVmean, respectively). Progression Free Survival (PFS) and Overall Survival (OS) at 3 and 4 years were computed by using Kaplan-Meier curves. Increased odds ratio was assessed using Cox regression analysis testing all lesion parameters measured by PET/CT. Results: PFS was significantly longer in patients with a negative than a positive restaging PET/CT study (3- and 4-years PFS 64% and 53% vs. 23% and 12%, respectively; $p<0.001$). Similarly, a negative study was associated with a significantly higher OS rate after 4 years of follow-up (67% vs. 25% in negative and positive group, respectively; $p<0.001$). Nodal or distant involvement were also independently associated with an increased risk of disease progression (HR 1.6 and 2.2, respectively, $p=0.003$). Moreover, PET/CT showed an incremental prognostic value compared to FIGO staging system, able to further stratify patient risk within the same staging assignment. At ROC analysis, no thresholds for semiquantitative parameters were predictive of a worse outcome. Conclusion: 18F-FDG PET/CT has an important prognostic value in assessing the risk of disease progression and mortality rate. An effective therapy planning might therefore effectively rely on 18F-FDG PET/CT findings. Semi-quantitative data were not proven to be an effective tool to predict disease progression.

OP303

Early 18F-FDG uptake as a reliable imaging biomarker of T790M-mediated resistance but not MET amplification in NSCLC

V. De Rosa[1], F. Iommelli[1], M. Monti[2], C. Mainolfi[2], R. Fonti[1], S. Del Vecchio[2]; [1]Institute of Biostructures and Bioimages, National Research Council, Naples, ITALY, [2]Department of Advanced Biomedical Sciences, University of Naples "Federico II", Naples, ITALY.

Aim: The two main mechanisms of resistance to EGFR tyrosine kinase inhibitors (TKI) in non-small cell lung cancer (NSCLC) are the occurrence of T790M secondary mutation in the kinase domain of EGFR and MET amplification. We previously showed that ^{18}F-FLT uptake is a reliable imaging biomarker of tumor response in refractory NSCLC due to both mechanisms of resistance. Here we tested whether ^{18}F-FDG PET/CT is able to detect the T790M- or MET-mediated resistance and to monitor the reversal of such resistance by EGFR T790M or MET inhibitors in tumor-bearing animals. Materials and Methods: Erlotinib-resistant NSCLC cell lines (H1975 and H1993) were treated with WZ4002, an EGFR T790M inhibitor, or the MET-inhibitor crizotinib depending on the mechanism of resistance. The levels and phosphorylation status of key proteins in the glycolytic cascade and oxidative phosphorylation were tested in response to treatment along with ^{18}F-FDG uptake. Then nude mice bearing H1975 and H1993 xenografts were subjected to ^{18}F-FDG PET/CT scan before and after treatment (50 mg/kg p.o. for 3 days) with erlotinib, WZ4002, crizotinib or vehicle. Three-dimensional region of interest analysis was performed to determine the percent change of ^{18}F-FDG uptake in response to treatment. At the end of imaging studies, tumors were removed, counted and analysed for glycolytic and mitochondrial proteins as well as signaling mediators. Results: H1975 cells showed a statistically significant reduction of ^{18}F-FDG uptake in response to treatment with WZ4002 (-61% ± 10%, $p=0.02$) whereas tracer uptake remained unchanged in response to erlotinib. H1993 cells, despite their known MET-mediated resistance, showed a decrease of ^{18}F-FDG uptake in response to erlotinib that became even stronger after treatment with the MET inhibitor (-70% ± 11%, $p=0.04$). Western blot analysis of glycolytic and mitochondrial proteins confirmed the different metabolic response of resistant H1975 and H1993 cells to erlotinib. In agreement with *in vitro* findings, imaging studies with ^{18}F-FDG PET/CT in H1975 tumor-bearing mice showed a strong reduction of ^{18}F-FDG uptake after treatment with WZ4002 whereas an increase of ^{18}F-FDG uptake was observed after treatment with erlotinib. Conversely, H1993 tumors bearing MET amplification showed a reduction of ^{18}F-FDG uptake after treatment with both crizotinib and erlotinib. The reduction of *in vivo* ^{18}F-FDG uptake was always associated with downregulation of key glycolytic proteins and upregulation of mitochondrial complexes in excised tumors. Conclusion: ^{18}F-FDG uptake is a reliable imaging biomarker of T790M-mediated resistance and its reversal in NSCLC whereas it fails to detect MET-mediated resistance.

OP304

Integrated 18F-FDG PET/MR imaging in the assessment of soft tissue sarcoma: initial experience with surgical and histopathological correlation

S. Vöö, D. Loeffen, R. Weijers, F. Mottaghy; Maastricht University Medical Center, Maastricht, NETHERLANDS.

Background. PET/MRI is an evolving hybrid imaging modality which combines the inherent strengths of MR with a high soft-

tissue contrast resolution and PET's functional metabolic capabilities.Goal. The objective of the present study was to evaluate whether integrated (18)F-FDG PET/MR imaging could improve the diagnostic workup in patients with soft-tissue sarcoma (STS) and its role in characterization and pre-operative staging of STS in comparison to MR.Material and Methods. Eleven patients (age range 42-72 years) with biopsy-proven STS who were referred for surgery were included in this prospective study. Preoperative FDG PET/MR was carried out in all patients with acquisition of T1W, T2W, short tau inversion recovery (STIR), and contrast-enhanced (ce) MR sequences. PET data were acquired simultaneously with the MR scan after injection of 199±58 MBq of (18)F-FDG. In addition, a skull-to-knee PET/MR (DIXON sequence) was acquired. Imaging results were correlated with the surgical and histologic findings.Results. The most common STS histologic type was malignant fibrous histiocytoma (30%). With regard to tumor grading, MR-based findings were in agreement with the PET findings in most of the cases (9/11, 81%). In 2 cases (19%) the metabolic findings on PET accurately indicated a low-grade STS, in agreement with histology and in contrast to the high-grade tumor suggested on MR images (T2W, ceMR). Tumor extent/invasiveness, as delineated on MR and PET, corresponded to surgical and histopathologic findings in majority of cases (7/11). However, in 4/11 cases the FDG-uptake on PET extended beyond the tumor delineation on MR. Histologic analysis confirmed a larger gross tumor volume and a deeper tumor invasiveness in the surrounding tissue in three cases, but reactive inflammatory changes in one case. These yielded an overall staging accuracy of 64% for MR and 91% for the hybrid PET/MR. In addition, PET/MR imaging revealed the presence of unexpected distant metastases in 18% of cases.Conclusion. MR alone is a robust modality in staging of STSs. However, combining (18)F-FDG PET with MR imaging on a hybrid PET/MR system results in greater accuracy with regard to overall staging and tumor delineation. Therefore, the combined modality of simultaneous PET/MRI is a valuable noninvasive diagnosis tool that could improve the clinical (pre-operative) decision in STS.

OP305

Evaluation of tumor hypoxia prior to and during radiotherapy in intermediate-risk prostate cancer using ^{18}F-Misonidazole PET/CT

M. Dore[1,2], S. Supiot[1,2], C. Cheze-Le-Rest[3], L. Ferrer[1,2], G. Delpon[1,2], M. Hatt[4], S. Guerif[3], D. Visvikis[4], **C. Rousseau**[1,2]; [1]Institut de Cancerologie de l'ouest Nantes, Saint Herblain, FRANCE, [2]INSERM UMR 892 CRCNA, Nantes, FRANCE, [3]University Hospital, Poitiers, FRANCE, [4]INSERM UMR 1101 LaTIM, Brest, FRANCE.

Aim: Since hypoxia is a major factor of radioresistance of prostate cancer (PC), we prospectively assessed hypoxia prior to and during radiotherapy treatment using ^{18}F-Misonidazole (FMISO) PET/CT.Method: Inclusion criteria were intermediate-risk PC patients planned to receive high-dose (>74 Gy) radiotherapy to the prostate without hormonal treatment. Prior to radiotherapy, all patients underwent a $FMISO_1$ PET/CT (45 min dynamic imaging, and late static imaging at 2,5h and 3,5h post-injection of 4 MBq/kg), as well as a trans-pelvic coil 1.5 T MRI and 18FCholine-PET. All images were co-registered using iPLANNET (Brainlab®). In $FMISO_1$-positive patients, a second $FMISO_2$ PET/CT was acquired after a minimal delivered dose of 18 Gy. FCholine and FMISO-positive volumes were segmented by the automated Fuzzy Locally Adaptive Bayesian (FLAB) method. In $FMISO_1$-positive patients, a dynamic analysis of early tumor uptake was performed. Results: Out of the 27 patients (median age 76 [65-81]), 7 and 9 patients were considered positive at 2.5h $FMISO_1$ PET/CT and 3.5h $FMISO_1$ PET/CT respectively. Median SUV_{max} and SUV_{max} tumor to muscle (T/M) ratio were respectively 3.4, 3.6 [1.9-8.2] for 2.5h $FMISO_1$ PET and 3.2, 4.4 [2.2-15.6] for 3.5h $FMISO_1$ PET/CT. Median $FMISO_1$-positive volume was 1.1 ml [0.4-2.4]. Time-activity curves extracted from dynamic images allowed to differentiate hypoxic volume from urine artifacts in 3 patients who had underwent transurethral resection of the prostate due to an abrupt rise of the curve at 20 min. During radiotherapy, $FMISO_2$-positive volumes were no longer detected in 5/9 patients, and $FMISO_2$-positive volume significantly decreased in the remaining 4 patients (median volume 0.7 ml [0.3-1.8]). A weak correlation was observed between $FMISO_1$-positive and MRI-, FCholine-positive areas (median Dice's coefficient=0.03 and 0.01 respectively). Conclusion: To the best of our knowledge, this is the first study showing that a small FMISO-positive volume can be detected in one third of intermediate-risk PC patients. Dynamic analyses could eliminate false positive areas related to urine excretion. Decreased hypoxic volumes were observed in all FMISO-positive patients, which suggests that fractionated radiotherapy induces tumor reoxygenation.

OP306

Multimodal imaging agents for sentinel node mapping as a means to (re)connect nuclear medicine to advances made in robot assisted surgery.

G. H. KleinJan[1,2], N. S. Van den Berg[1,2], E. Wit[2], E. Vegt[2], F. W. B. Van Leeuwen[1], H. G. Van der Poel[2]; [1]Leiden University Medical Centre, Leiden, NETHERLANDS, [2]NKI-AVL, Amsterdam, NETHERLANDS.

Introduction: Prostatectomies and complementary extended

pelvic lymph node dissection (ePLND) of (sentinel) lymph nodes (LN) at risk of containing metastases are increasingly being performed using high-tech robotic approaches. Although this technological evolution has clear surgical advantages, the physical nature robotic systems limits integrated use of routine radioguided surgery technologies. This limitation has driven robotic engineering efforts towards the integration of fluorescence rather than radioguidance. We here present an attempt to reconnect the robotic developments to nuclear medicine, by making use of a hybrid tracer (radioactive and fluorescent) that allows for fully integrated preoperative nuclear imaging and intraoperative fluorescence guidance towards sentinel nodes (SN). Methods: Fifty patients with a Briganti nomogram-based risk >10% of lymph node (LN) metastases were included. After indocyanine green (ICG)- 99mTc-nanocolloid injection, nuclear imaging was performed to locate the SN(s). The 3D information of the SPECT-CT was used by the surgeon to plan the operation with a da Vinci Si robotic system equipped with a Firefly near-infrared fluorescence endoscope. Intraoperatively, fluorescence guidance was used to optically identify the preoperatively defined SN(s); fluorescence imaging (FI) could be conveniently (dis)activated during the resection using a simple hand-switch. The number and location of the intraoperatively identified SNs, the in vivo and ex vivo fluorescence-based SN identification rate and radioactivity measurements, and the tumor status of SNs and LNs removed with ePLND were recorded and analyzed. Results: Based on SPECT-CT imaging a total 201 SNs (median 4) were identified of which 54 (26.9%; median 1) were located outside the standard ePLND. During surgery, 34 SNs could not be resected based on their location (e.g mesorectal fascia) and/or the risk of complications. FI was integrated into the surgical process and thereby helped to identify 15 additional SNs not previously identified on preoperative imaging. In total, 182 SNs were intraoperatively excised of which 82% were identified with the Firefly in vivo (ex vivo: 98%) could be identified with FI. All excised SNs were radioactive. With ePLND an additional 589 LNs were removed (median 10). Histopathological evaluation revealed tumor-positive SNs in 26% of patients (n=13). In 11 of these, the SN(s) was the only tumor-positive node. In two patients besides a tumor-positive SN, additional tumor-positive LNs were found. In one node positive patient, the SN was negative (false positive rate 7%). Conclusion: With the hybrid tracer preoperative SPECT/CT imaging information can be integrated into state-of-the-art surgical robotics, where it complements fluorescence-based SN identification.

OP307

68Ga-OPS202/177Lu-OPS201, a high performance theranostic pair of radiolabelled somatostatin antagonists for PET imaging and radionuclide therapy: translational aspects

G. P. Nicolas[1], R. Mansi[1], F. Kaul[1], S. Vomstein[1], J. Kaufmann[2], H. Bouterfa[2], D. Wild[1], M. Fani[1]; [1]University Hospital Basel, BASEL, SWITZERLAND, [2]OctreoPharm Sciences GmbH, BERLIN, GERMANY.

Aim: To evaluate the somatostatin receptor (sst2)-antagonist Cpa-c(DCys-Aph(Hor)-DAph(Cbm)-Lys-Thr-Cys)-DTyr-NH_2 (JR11), for PET imaging and peptide receptor radionuclide therapy (PRRT) of neuroendocrine tumours (NETs) and address translational aspects related to clinical applications. Materials and Methods: Comprehensive *in vivo* evaluation of ^{177}Lu-OPS201 (^{177}Lu-DOTA-JR11) was performed in HEK-hsst2 xenografts comparatively to ^{177}Lu-DOTA-TATE. The influence of the peptide mass was assessed by a mass escalation study in HEK-hsst2 and AR42J xenografts. Various biodistribution modifiers were tested, including kidney protection agents and i.v. injections of octreotide. In parallel, a phase I/II clinical trial was initiated, comparing two microdoses (15 and 50 μg) of ^{68}Ga-OPS202 (^{68}Ga-NODAGA-JR11) PET/CT with ^{68}Ga-DOTA-TOC in the same 12 patients with NETs (ClinicalTrials.gov NCT02162446). Results: ^{177}Lu-OPS201 showed 2.6-times higher tumour dose and 1.8-fold higher kidney dose, resulting in 34% more favourable tumour-to-kidney dose ratio compared to ^{177}Lu-DOTA-TATE. Biodistribution and nanoSPECT/CT showed that escalating the injected peptide mass of ^{177}Lu-OPS201 from 10 to 200 pmol drastically improved the tumour-to-background uptake ratios in HEK-hsst2 and AR42J xenografts: tumour-to-liver increased from 16 to 52 and from 30 to 54, respectively and tumour-to-bone-marrow from 25 to 97 and from 23 to 93, respectively, 4h p.i. However, tumour-to-kidney ratios remained mostly unchanged. Pre-injection of lysine, gelofusin or combination of both decreased the kidney uptake of ^{177}Lu-OPS201 about 40%. Interestingly, 200-fold excess of octreotide seemed to have no influence on the distribution of the antagonist, including the tumour uptake. In patients, both ^{68}Ga-OPS202 doses showed improved tumour-to-background ratios compared to ^{68}Ga-DOTA-TOC PET/CT. Especially, matched liver metastases (visible on all 3 scans) showed a factor of 2 increase in tumour-to-liver-background uptake ratios (mean±σ) 4.4±3.5 (15 μg)/4.9±3.9 (50 μg) vs 2.1±1.5 for ^{68}Ga-DOTA-TOC. The 50 μg dose seemed to further decrease the uptake of ^{68}Ga-OPS202 in the sst2-positive organs compared to 15 μg, e.g. in the spleen (11.5±5.1/10.3±3.0), pancreas (2.7±1.1/2.3 ±0.7) and intestine (3.6±1.5/3.0±0.9), compared to ^{68}Ga-DOTA-TOC (27.9±11.5, 4.1±1.5 and 5.5±1.2, respectively). Conclusion: Increased image contrast of ^{68}Ga-OPS202, along

with an advantageous tumour-to-kidney dose ratio of ^{177}Lu-OPS201, is expected to improve sensitivity and diagnostic accuracy of PET/CT imaging and safety window of PRRT in NET patients, compared to the agonists. An optimized peptide mass of the radiolabelled antagonist is likely to further enhance the performance of this promising theranostic pair. First *in vivo* pre-clinical data indicated that, when using sst2 antagonists for PRRT, octreotide treatment may not be interrupted.

OP308

First results with Lu-177-PSMA617 in targeted radionuclide therapy of patients with metastatic hormone-refractory prostate cancer

C. Kratochwil[1], F. L. Giesel[1], A. Afshar-Oromieh[1], M. Benešová[2], W. Mier[1], M. Eder[2], K. Kopka[2], U. Haberkorn[1]; [1]University Hospital Heidelberg, Heidelberg, GERMANY, [2]Division of Radiopharmaceutical Chemistry, German Cancer Research Center (DKFZ), Heidelberg, GERMANY.

Objectives:We report our clinical experience with PSMA targeted radionuclide therapy of patients with metastatic hormone-refractory prostate cancer in regard to toxicity and treatment effects using Lu-177-PSMA617, a PSMA ligand consisting of a DOTA-chelate tagged to the Glu-urea-Lys motif via an aromatic linker which further improves tumor accumulation while reducing kidney uptake.Methods:We retrospectively evaluate 35 patients that received therapy with Lu-177-PSMA617 in our department. All patients were hormone- and taxan-refractory or taxanes were contraindicated and the oncological status was progressive. A PSMA-positive tumor phenotype was previousely validated with PSMA-PET/CT (Ga-68-PSMA-11, Glu-urea-Lys-Ahx-HBED-CC), respectively. Acute hematotoxicity was evaluated with lab tests and clinical exam according to CTCEA criteria and response was evaluated with PSA sampling and radiologic follow-up.Results:In patients with multifocal bone lesions but no bone marrow-carcinosis (no superscan in bone scintigraphy) 6 GBq Lu-177-PSMA617 every 2 months was found to be tolerable in regard to hematotoxicity. Other common side effects were xerostomia, less common fatigue and seldom unspecific intestinal disorders. Dosimetry presents kidney doses of less than 1 Gy per 1 GBq Lu-177-PSMA617 and no renal toxicity was observed, yet. Five patients, who were in end-stage situation when receiving the therapy, died before follow-up imaging. PSA-response was observed in the majority of the patients. After 3 cycles (6-9 months) PSA progression re-occurred in ca. 50% of the patients. In the other 50% sustainable biochemical and radiologic response was observed including one patient with complete remission in PSMA-PET.Conclusions:Radionuclide therapy with Lu-177-PSMA617 demonstratesa favorable therapeutic range and can induce biochemical as well as radiologic responses with moderate acute toxicity. Clinical trials evaluating PFS and OS are encouraged.

OP309

Baseline 18F-FDG PET/CT Predicts Progression-Free Survival After Radium-223

E. Etchebehere, J. Araujo, G. Ray, D. Milton, N. Swanston, H. Macapinlac, E. Rohren; The University of Texas MD Anderson Cancer Center, Houston, TX, UNITED STATES.

AIM: The purpose of this study was to evaluate if whole-body ^{18}F-FDG PET/CT is able to predict which patients will benefit from Radium-223 therapy (Ra-223). MATERIALS AND METHODS: We retrospectively reviewed 26 histologically confirmed hormone-refractory prostate cancer patients (52-84 y old; mean 69 ± 9 yrs.) with bone metastases (without visceral metastases). The patients were submitted to an 18F-FDG PET/CT scan prior to Ra-223. Overall survival (OS) was the primary end point. Secondary end points were progression-free survival (PFS) and bone event-free survival (BeFS). We evaluated the presence of nodal metastases, the total number of radium cycles (Ra_{Tot}) and the following 18F-FDG PET/CT parameters: the highest SUVmax of a bone metastasis (*h*-SUVmax), the TLG of bone metastases (TLG_{Bone}) and TLG of bone and nodal metastases (TLG_{All}). RESULTS: The median follow-up time was 6.14 months (0.36-9.72 months). Eight (31%) patients presented nodal metastases prior to Ra-223. Fourteen (54%) patients received all 6 Ra-223 cycles, three (12%) were still in progress and 9 (35%) discontinued Ra-223. Reasons for withdrawal from Ra-223 were: progression (n=6), hematologic toxicity (n=1), declining ECOG status (n=1) and/or a bone event (n=1). During Ra-223, four patients died, 11 (42%) progressed and six (23%) had a bone event. The median OS was not reached (less than 50% of the patients died), the median PFS was 5.91 months and the BeFS was 8.61 months. In a univariate model, Ra_{TOT} was associated with OS (HR=0.38; p=0.018), PFS (HR=0.55; p<0.001) and BeFS (HR=0.45; p=0.001). Each additional cycle of Ra-223 was associated with a 62% reduction in the risk of death, a 45% reduction in risk of progression or death and a 55% reduction in risk of experiencing a bone event or death. PFS was significantly associated with *h*SUVmax (HR=1.39; p=0.002) and marginally associated with TLG_{Bone} (HR=1.69; p=0.0520) and TLG_{All} (HR=1.70; p=0.051). A *h*SUVmax cutoff ≥ 5.6 (p=0.003) and a TLG_{Bone} cutoff ≥ 240 (p=0.006) separated patients with a shorter PFS. BeFS was not associated with any of the FDG-PET/CT parameters nor with the presence of nodal metastases. CONCLUSIONS: Baseline 18F-FDG PET/CT is able to predict PFS during Ra-223. A one-unit increase in *h*SUVmax was associated with a 39% increase in risk of

progression or death. Patients with hSUVmax below 5.6 had a longer progression-free survival. More Ra-223 cycles were beneficial and reduced the risk of death, progression and the risk of a bone event.

OP310

64Cu-ATSM PET/CT in solid tumours: *a prognostic evaluation for disease outcome*

E. Lopci[1,2], I. Grassi[3], S. Cambioli[3], A. Gamboni[4], F. Salvi[5], G. Cicoria[3], F. Lodi[3], C. Dazzi[6], S. Mattioli[7], S. Fanti[3]; [1]Humanitas Clinical and Research Hospital, Milano, ITALY, [2]Alma Mater Studiorum University, Bologna, ITALY, [3]University Hospital S. Orsola-Malpighi, Bologna, ITALY, [4]Ospedale degli Infermi, Faenza, ITALY, [5]Ospedale Bellaria, Bologna, ITALY, [6]Istituto Oncologico Romagnolo, Ravenna, ITALY, [7]Alma Mater Studiorum, Bologna, ITALY.

Purpose: 64Cu-ATSM is a well-known PET radiopharmaceutical applied for tumour imaging of hypoxia. One of the advantages of this compound compared to other hypoxia-avid tracers is the high tumour-to-background signal offered, which guaranties a facilitated tumour delineation. The current study aimed at analyzing optimal semi-quantitative and quantitative parameters obtained by 64Cu-ATSM PET/CT in the same cohort of patients with special focus on their correlation to disease outcome. Materials and Methods: A prospective recruitment of 18 consecutive patients (M:F=13:5; mean age 60.7 years) with locally advanced NSLCL (n=7) or head and neck cancer (HNC) was performed. Each participant received 105-500MBq of tracer according to body size and was scanned in a 3D-mode on a PET/CT tomograph 60 minutes after tracer injection. PET images were reconstructed and visualized on a GE Advanced 4.6 workstation for the definition of semi-quantitative and quantitative parameters: SUV_{max}, $SUV_{ratio\text{-}to\text{-}muscle}$, SUV_{mean}, hypoxic volume (HV) and hypoxic burden ($HB=HV*SUV_{mean}$). These data were subsequently correlated to disease outcome, expressed in terms of progression-free survival (PFS) calculated on a follow-up period of median 14.6 months. Results: All patients showed a moderately to highly increased uptake of 64Cu-ATSM in tumour lesions, with a mean SUV_{max} of 5.2 (range 1.9-8.3), mean SUV_{ratio} of 4.4 (range 1.6-6.8) and SUV_{mean} of 2.8 (range 1.0-6.8). Also a broad range of HV and HB was defined, with as mean values 99.3cm^3 (range 2.5-453.7) and 301 (4.2-1134), respectively. The ROC analysis identified as reference cut-offs with respect to disease outcome the following values: SUV_{max} >2.5 (AUC 0.57; sens. 88.9%; spec.50%), SUV_{ratio} ≤4.4 (AUC 0.60; sens. 50; spec. 83.3%), SUVmean >1.5 (AUC 0.61; sens. 88.9%; spec. 50%), HV >160.7cm^3 (AUC 0.61; sens. 55.6%; spec. 75%), HB >160.7 (AUC 0.67; sens. 58.3%; spec.83.3%). In our cohort, tumour hypoxic burden (HB) showed a statistically significant difference in terms of mean values on the ANOVA test with respect to disease progression (p=0,038). On univariate analysis, the Cox regression confirmed these findings and showed a significant correlation to PFS for HB (p=0.05) and tumour hypoxic volume (p=0.019). Conclusions: In our cohort, the definition of optimal semi-quantitative and quantitative parameters on 64Cu-ATSM PET/CT appears feasible and in line with previously published data. However, when considering the prognostic role with respect to disease outcome, the more robust parameters are represented by hypoxic tumour volume (HV) and hypoxic burden (HB).

GLP-1 analogue liraglutide prevents decline of brain glucose metabolism in Alzheimer's Disease: Randomized, placebo-controlled double-blinded clinical trial

M. Gejl[1], L. Egejord[2], A. Møller[1], S. B. Hansen[1], K. Vang[1], A. Rodell[1], H. Brændgaard[1], H. Gottrup[1], A. Schacht[1], N. Møller[1], B. Brock[1], J. Rungby[2], A. Gjedde[3]; [1]Aarhus University Hospital, Aarhus, DENMARK, [2]Aarhus University, Aarhus, DENMARK, [3]University of Copenhagen, Copenhagen, DENMARK.

Introduction: Type 2 Diabetes Mellitus (T2D) increases the risk of Alzheimer's disease (AD) and vice versa. Suggested common pathophysiological mechanisms include deficient insulin and glucagon-like-peptide-1 (GLP-1) signalling. In rodent models of AD, the GLP-1 receptor agonist liraglutide limits amyloid (Aβ) deposition and inflammation, blocks memory deterioration, and may normalize glucose consumption. As a surrogate marker of synaptic dysfunction and neuronal activity, [18F]fluorodeoxyglucose ([18F]FDG) uptake in brain is sensitive to disease progression. The decline of the cerebral metabolic rate of glucose (CMRglc) is closely related to cognitive impairment. We predicted that treatment with liraglutide would reduce the accumulation of Aβ and improve CMRglc measured with positron emission tomography (PET) of AD patients. Materials and methods: In this 26-week, randomized, double-blind, placebo-controlled trial, we randomized 38 patients with moderately advanced AD to treatment either with liraglutide (n=18) or with placebo (n=20) as add-on medication. We mapped the changes of regional Aβ loads and cerebral blood flow (CBF) values in brain from the early and late phases of tracer Pittsburgh compound B ([11C]PIB) uptake and retention in brain, and the changes of CMRglc from the uptake of FDG, both with PET. We also monitored changes of cognition by means of the WMS-IV scale. Results: During the 26 weeks, the [11C]PIB retention increased significantly in the temporal lobes of both placebo ($P = 0.04$) and liraglutide groups ($P = 0.04$), and in the occipital lobe of the liraglutide-treated group ($P = 0.04$), but the increases did not differ between the two groups ($P \geq 0.38$). The expected correlation between values of CMRglc and CBF, confirmed at baseline and in the placebo-treated patients, was absent in patients treated with liraglutide. The CMRglc declined significantly in the placebo group ($P<0.05$) in precuneus ($P = 0.009$), and the parietal ($P = 0.04$), temporal ($P = 0.046$), and occipital lobes ($P = 0.009$), and in cerebellum ($P = 0.04$). In contrast, patients treated with liraglutide had a numerical, albeit insignificant, increase of CMRglc after the six months of treatment. Cognition was unchanged during the trial in both groups. Conclusion: In AD

patients, liraglutide treatment prevented the decline of CMRglc seen in placebo-treated patients where it signifies cognitive impairment, synaptic dysfunction, and disease evolution. We tentatively ascribe the loss of CBF-CMRglc coupling by liraglutide to altered lactate signalling in the neurovascular unit.

OP323

A randomized, controlled, multicenter, international study of the impact of florbetapir (18F) PET amyloid imaging on patient management and outcome

M. Pontecorvo[1], M. Grundman[2], B. Dubois[3], F. Nobili[4], C. Sadowsky[5], A. McGeehan[1], M. Lowrey[1], A. Dudek[1], M. Flitter[1], G. Dell'Agnello[6], A. Chevrette[7], W. Deberdt[7], A. Arora[1], M. D. Devous Sr[1], M. Mintun[1]; [1]Avid Radiopharmaceuticals, Philadelphia, PA, UNITED STATES, [2]Global R&D Partners, LLC and University of California, San Diego, San Diego, CA, UNITED STATES, [3]Salpêtrière Hospital, Paris, FRANCE, [4]University of Genoa (DINOGMI), Genoa, ITALY, [5]Nova SE University, Fort Lauderdale, FL, UNITED STATES, [6]Eli Lilly Italia, Sesto Fiorentino, ITALY, [7]Eli Lilly France, Paris, FRANCE.

Aim: The study evaluated the impact of amyloid PET on patient management and outcomes in a multicenter, randomized, controlled study.M ethods: Physicians in France, Italy and the US identified patients seeking diagnosis for MCI or dementia, where AD was considered a possible (<85% certain) cause. They recorded a working diagnosis and management plan including any plans for diagnostic and neuropsychological testing, follow-up and referral visits, and any medications planned to improve cognition. Patients underwent a florbetapir PET scan and were then randomized to either immediate or delayed (1 year) feedback regarding amyloid status (positive: Aβ+, negative: Aβ-). Patients returned after 3 months and the physician updated the diagnosis and constructed a summary of actual management, including neuropsychological and diagnostic testing actually performed, followup/referral visits that occurred and medications actually used to treat cognitive impairment since the post-scan visit. Patients returned to the center one year post-baseline for assessment of patient and caregiver outcome. Change in patient cognitive status was assessed with the ADAScog (investigators were blinded to the baseline ADAScog). Patient and caregiver health outcomes and quality of life were assessed at both 3 months and one-year with the RUD, EQ-5D, Geriatric Depression, QoL-AD, Zarit Burden and the Self Efficacy for Managing Dementia scales. It was hypothesized that outcomes would be worse for Aβ+ than for Aβ- patients (i.e., reflecting the impact of Alzheimer's disease) and that this effect might be mitigated for Aβ+ subjects in the immediate feedback group. Results: A total of 618 subjects were randomized to the immediate (308) or to the delayed (310) PET feedback arms, including 174 subjects in France, 221 in Italy and 223 in the US. 599 completed the 3 month and 560 completed the one-year follow-up visits, with the last visit conducted in April 2015. Analyses are ongoing. Preliminary results indicate that the percentage of patients for whom the actual management composite observed at 3 months was different from the baseline management plan (the protocol specified primary outcome) was significantly greater for the group that received immediate feedback regarding amyloid status than for those with delayed feedback. Three month and 1 year results will be presented for both the study as a whole and for individual European countries. Conclusions: This is the first large multicenter randomized controlled study of the clinical impact of amyloid PET and may help guide the use of amyloid PET imaging at both the global and country level.

OP324

18F-Florbetaben PET Imaging of Morphologically Distinct Amyloid β Deposits

O. Sabri[1], A. M. Catafau[2], H. Barthel[1], J. Seibyl[3], B. Ghetti[4], J. Leverenz[5], J. W. Ironside[6], S. Bullich[2], W. Schulz-Schaeffer[7], A. Hoffmann[8]; [1]Leipzig University, Leipzig, GERMANY, [2]Piramal Imaging, Berlin, GERMANY, [3]IND, New Haven, CT, UNITED STATES, [4]Indiana University School of Medicine, Indianapolis, IN, UNITED STATES, [5]Cleveland Lou Ruvo Center for Brain Health, Cleveland, OH, UNITED STATES, [6]University of Edinburgh, Edinburgh, UNITED KINGDOM, [7]Georg August University Göttingen, Göttingen, GERMANY, [8]Bayer Pharma, Berlin, GERMANY.

Aim: Post mortem histopathology is still regarded as gold standard to diagnose Alzheimer's disease (AD). Morphologically distinct amyloid β(Aβ) deposits, such as diffuse or neuritic Aβ plaques (DIFF, NEUR), and vascular Aβ (VASC) may be present in this disorder. Aβ PET imaging recently emerged as a promising alternative to potentially shift the gold standard AD diagnosis to in vivo. 18F-Florbetaben (FBB) has been validated as a biomarker of NEUR. It was the aim of this project to investigate the impact of the different forms of Aβ deposits on FBB PET scans. Materials and methods: Brain tissue was collected from 87 end-of-life patients (age 80 ±10yrs; 64 AD, 14 other dementia, 9 non-demented) who underwent a FBB PET scan before death. Aβ immunohistochemistry (IHC) was used for assessment of VASC. Aβ IHC and Bielschowsky silver stain were used for assessment of NEUR and DIFF in frontal, occipital, anterior cingulate and posterior cingulate cortices. From the total of 87x4=348 samples, 329 were finally assessed, and classified as Aβ absent (none or sparse) or present (moderate or frequent). Cortical standardized uptake value ratios (SUVRs) were obtained in all regions of interest (ROIs) using cerebellar grey matter as reference region. A linear regression model was fitted for each

ROI as: SUVR=a0+an×n+ad×d+av×v, where a0, an, ad, av are constants, and n=NEUR, d=DIFF and v=VASC. n, d, and v were assigned two values: 0=Aβ absent; 1=Aβ present. Results: In ROIs with high frequency of Aβ (frontal, posterior cingulate cortex), both DIFF (ad=0.32 and 0.42) and NEUR (an=0.27 and 0.21) contributed significantly to the SUVR. In ROIs with low frequency of Aβ (occipital, anterior cingulate cortex), only DIFF contributed significantly to the SUVR (ad=0.24 and 0.55). The presence of VASC contributed significantly to the SUVR only in the occipital ROI (av=0.13). Conclusion: There was a significant impact of DIFF on FBB SUVRs in brain regions with low Aβ load, supporting the use of FBB in detecting early stages of Aβ deposition. The impact of VASC on FBB SUVRs was only significant in the occipital cortex. These results underline the importance of measuring the topographic distribution of Aβ aggregates, and suggest potential utility of FBB in detecting cerebral Aβ angiopathy. Research support: Piramal Imaging, Berlin, Germany

OP325

18F-Florbetaben beta-amyloid PET scan quantification: Do cerebellar plaques influence SUVR?

A. M. Catafau[1], S. Bullich[1], J. Seibyl[2], H. Barthel[3], B. Ghetti[4], J. B. Leverenz[5], J. W. Ironside[6], W. J. Schulz-Schaeffer[7], A. Hoffmann[8], O. Sabri[3]; [1]Piramal Imaging GmbH, Berlin, GERMANY, [2]Molecular Neuroimaging, New Haven, CT, UNITED STATES, [3]Leipzig University, Leipzig, GERMANY, [4]Indiana University School of Medicine, Indianapolis, IN, UNITED STATES, [5]Puget Sound Health Care System and University of Washington, Seattle, WA, UNITED STATES, [6]University of Edinburgh, Edinburgh, UNITED KINGDOM, [7]Georg-August University Göttingen, Göttingen, GERMANY, [8]Bayer Pharma AG, Berlin, GERMANY.

Aim: Standardized uptake value ratios (SUVR) using cerebellar grey matter as the reference region are commonly used for quantification of 18F-Florbetaben (FBB) scans. However, cerebellar plaques may be present in Alzheimer disease (AD). The aim of this study was to assess the influence of cerebellar plaques in FBB SUVR, when using cerebellar grey matter as the reference region. Materials and methods: Cerebral (frontal, occipital, anterior and posterior cingulate) cortex and cerebellar cortex tissue from 87 end of life patients (64 AD, 14 other dementia, 9 non-demented aged volunteers; 80.4±10.2 yrs) who underwent a FBB PET before death was neuropathologically assessed using the Bielschowsky silver stain and Amyloid β (Aβ) immunohistochemistry. Neuritic/cored and diffuse plaques were rated as absent, sparse, moderate and frequent. Cerebral cortical SUVRs were compared among brains with different cerebellar plaque loads. Results: None from the 83 evaluable cerebellar samples showed frequent plaques. Sparse diffuse plaques were found in 33 samples, and moderate diffuse plaques in 5. Only 1 sample showed both sparse neuritic/cored and sparse diffuse plaques. Subjects with higher cerebellar plaque loads showed higher cerebral cortical Aβ loads and higher cerebral cortical standardized uptake values. Thus, cerebral cortical SUVRs significantly increased with cerebellar plaque load (range from 1.36 (cerebellar plaques absent) to 1.86 (cerebellar plaques moderate) across regions, all p values <0.004). However, in cerebral cortical regions with moderate or frequent Aβ plaques no significant SUVR differences were found among brains showing different cerebellar plaque loads (all p values >0.39). Conclusions: In brains with higher cerebral cortical Aβ loads, cerebellar plaques were found in 47% of cases, mostly as sparse diffuse plaques (40%). The presence of cerebellar plaques did not influence the SUVRs in subjects with moderate or frequent cortical Aβ. Therefore, the effect of cerebellar plaques in FBB SUVR appears to be negligible even in advanced stages of AD with a high cortical Aβ load.

OP326

Clinical [^{18}F]Florbetaben-PET Imaging - Benefit of Early Acquisition

S. Daerr[1], M. Brendel[1], C. Zach[1], A. Danek[1], H. Barthel[2], O. Sabri[2], P. Bartenstein[1], **A. Rominger**[1]; [1]University of Munich, Munich, GERMANY, [2]University of Leipzig, Leipzig, GERMANY.

Objectives: In the last few years [^{18}F]-labelled amyloid PET radiotracers have been developed and recently received clinical approval. We now report on our experience with a heterogenous patient cohort using [^{18}F]Florbetaben (FBB) PET. A major goal was to investigate the benefit of an additionally performed early post injection acquisition of the FBB-PET. Methods: All subjects for amyloid imaging were recruited in a clinical setting. Aside from undergoing a detailed neuropsychiatric test battery, collection of biomarkers (MRI, CSF, FDG-PET) was performed as well. Furthermore 300 MBq [^{18}F]Florbetaben were injected i.v. and PET scans were routinely acquired 90 min p.i., and an early acquisition starting just after injection was performed in a subset of patients. Visual comparison and semiquantitative correlation analyses were performed between FDG- and early FBB uptake. Results: A total of 105 patients (mean age 70.3±9.5y) were scanned. In a subset of 44 patients an early acquisition of the FBB-PET could be performed, in 35/44 patients the individual FDG-PET was available. In 16/35 cases the regularly acquired amyloid PET was read negative, 19/35 cases were amyloid-positive. When the early acquisition of FBB was processed in

Neurostat and compared to a normative database, the visual interpretation resembled the pattern of the individual FDG-PETs, irrespective of the amyloid-status in the late FBB-scans. The semiquantitative correlation analyses ranged from R=0.78 to R=0.94 ($p<0.01$) in different brain regions assessed, altogether resembling good-to excellent correlation features between early FBB and FDG-metabolism. Conclusions: We report on the clinical use of Florbetaben-PET in a non-selected patient cohort. Early [^{18}F]Florbetaben acquisitions as a perfusion-like marker closely resembled FDG-PET findings. These findings need to be further investigated in a larger patient cohort, but could potentially substitute an additional FDG-PET scan in the future.

OP327

Resveratrol in Alzheimer's disease: a PIB positron emission tomography/computed tomography study

A. Damian[1], A. de la Fuente[2], G. Castellano[3], E. Savio[2], P. Buccino[2], B. Aguiar[4], A. Quagliata[1], F. Cano[3], M. Gonzalez[2], S. Dansilio[4], A. Kmaid[5], I. Savio[5], H. Engler[2]; [1]Uruguayan Centre of Molecular Imaging (CUDIM); Nuclear Medicine Centre, University of the Republic, Montevideo, URUGUAY, [2]Uruguayan Centre of Molecular Imaging (CUDIM), Montevideo, URUGUAY, [3]Department of Social and Preventive Medicine, University of the Republic, Montevideo, URUGUAY, [4]Department of Neuropsychology, University of the Republic, Montevideo, URUGUAY, [5]Department of Geriatrics, University of the Republic, Montevideo, URUGUAY.

Resveratrol (trans-3,5,40-trihydroxystilbene) is a polyphenol that has shown potential beneficial effects in cardiovascular and neurodegenerative disorders. Although it has been proved that resveratrol promotes vasodilatation, the regional changes in cerebral blood flow (CBF) induced by this polyphenol have not been fully assessed yet. Pittsburgh Compound B (PIB) is a lipophilic thioflavin derivative PET tracer used to detect amyloid depositions, for example in patients with Alzheimer's Disease (AD). The molecules of resveratrol and PIB have structural similarities, which can indicate possible similar interactions with amyloid depositions. Additionally, it has been published that early images of the PIB scans can be used as an indicator of CBF.Aim: To assess the possible effect of a short treatment with resveratrol on the amyloid deposition images with PIB PET and on a rough index of CBF.Materials and methods: Prospective study that included twelve PIB positive AD patients (58-85 years old, 5 men) that underwent clinical and extensive neuropsychological examination. The mean progression time from diagnosis was 2.6±2.2 (SD) years, with a mean Mini-mental state examination score of 22.5±3. After the first PIB positive scan, the patients were treated with oral administration of 1 g trans-resveratrol daily during 8 days. A second PIB scan was performed the last day of treatment. Parametric images of the first 6 min (eSUV and ePIB normalized to the cerebellum) and the last 20 min (tSUV and tPIB) of the PIB scans were obtained and analyzed using predefined Volumes of Interest (VOIs) and a voxel based approach with the software Statistical Parametric Mapping (SPM8). Results: The analysis of changes in amyloid depositions (tPIB and tSUV) did not reveal significant differences before and after the treatment with Resveratrol in any region of the cortex. Voxel based analysis of the early images (eSUV) of the PIB scans showed an increased uptake in the occipital cortex bilaterally after the treatment with Resveratrol ($p<0.001$, uncorrected for multiple comparisons, 100 voxels extent threshold) with a minor extension to the left inferior parietal lobe. We couldn't find a significant correlation between eSUV and ePIB.Conclusions: There were not changes in amyloid depositions after a week of treatment with Resveratrol. Changes in the early distribution of PIB, interpreted as an increased CBF, were observed in the occipital and inferior parietal cortex. Further studies with specific CBF tracers are needed to study the regional effect of resveratrol in brain perfusion.

Partition model absorbed dose biases and variability due to tumor-to-normal-liver ratios following 90Y microsphere therapy

J. Mikell[1,2], A. Mahvash[1], W. Siman[1,2], F. Mourtada[3], **S. C. Kappadath**[1,2]; [1]UT MD Anderson Cancer Center, Houston, TX, UNITED STATES, [2]UT Graduate School of Biomedical Sciences, Houston, TX, UNITED STATES, [3]Christiana Care Health System, Newark, DE, UNITED STATES.

Aim: Partition model (PM) assumes uniform distribution of 90Y microspheres within tumors (T) and non-tumoral (NT) compartments. In addition, it assumes a single scalar (TNR) to describe the relative activity concentration (AC) of 90Y microspheres between T and NT. However, clinical reality presents multiple tumors that have different uptake and non-uniform AC. Monte Carlo (MC) provides voxel-based absorbed dose distributions throughout T and NT volumes. Only in the ideal case of uniform uptake to a single T and uniform uptake to NT will the mean absorbed dose estimates from PM equal MC. In this work we calculate 1) the differences between PM and MC for mean absorbed doses to T and NT, and 2) the variability of PM doses on estimates of TNR. Various TNR were calculated using 1) mean tumor AC (meanT), 2) maximum tumor AC (maxT), and 3) four estimates of mean NT AC. Materials and Methods: We analyzed

21 90Y glass-microsphere cases; 7 were single tumor cases. MC absorbed doses were calculated from quantitative 90Y SPECT/CT. Tumors and livers were segmented by radiologist. PM tumor uptake was characterized by meanT and maxT; volume-weighting was used for multiple tumors. PM NT uptake was characterized by mean AC of the entire NT VOI (meanNT) and mean AC of three spheres (D=2.5cm) placed in different locations within NT by radiologist. We generated eight estimates of TNR and consequently eight estimates of absorbed dose to T and NT. We assessed the differences (%Δ) of PM absorbed dose estimates relative to MC and the variability (coefficient of variation, COV) of PM absorbed doses due to TNR. Results: For single tumors using TNR=meanT/meanNT, the average %Δ and (range) was 70%±24% (31% to 99%) for T and 71%±26% (23% to 90%) for NT. For multiple tumors using TNR=volume-weighted-meanT/meanNT, the average %Δ and (range) was 103%±119% (-28% to 476%) for T and 54%±21% (20% to 99%) for NT. For single tumors using TNR=maxT/meanNT, the average %Δ was 192%±89% (53% to 295%) for T and 2%±58% (-65% to 65%) for NT. The PM absorbed dose COV due to TNR variability for single (multiple) tumors was 0.32±0.17 (0.32±0.16) for T and 0.42 ±0.29 (0.23±0.29) for NT. Conclusion: There are large biases and high variability in PM absorbed dose estimates for T and NT stemming from the uncertainties in the TNR that hold true even in the best case scenario of single tumors. Grant support NIH/NCI R01 CA138986.

OP329

99mTc-MAA SPECT/CT lung shunt estimations are more accurate than those obtained from planar scintigraphy

J. Prince, A. F. van den Hoven, G. C. Krijger, N. de Wit, B. J. van Nierop, M. N. G. J. Braat, M. A. A. J. van den Bosch, H. M. Verkooijen, M. G. E. H. Lam; UMC Utrecht, Utrecht, NETHERLANDS.

Aim: Shunting of yttrium-90 microspheres to the lungs can preclude radioembolization if the estimated absorbed lung dose after treatment is >30 Gy on ^{99m}Tc-MAA planar scintigraphy. The objective of this study was to investigate the validity of planar scintigraphy lung shunt after ^{99m}Tc-MAA compared with SPECT/CT and to identify risk factors for a high lung shunt. Materials and methods: Between March 2011 and November 2013 patients eligible for radioembolization were included in this retrospective, cross-sectional, single-center study. The lung shunt fraction after ^{99m}Tc-MAA injection was measured by dividing the counts in the lungs by the counts in the lungs and liver. The absorbed dose (Gy) on SPECT/CT was based on the estimated MBq/mL in the basal lung assuming a homogeneous density and distribution. Univariable analyses were used to test for association ($p<0.05$) between the occurrence of lung shunting on planar scintigraphy or SPECT/CT and the following risk factors: tumor type, tumor burden in the target volume (in %), angioinvasion, extrahepatic disease, and time between ^{99m}Tc-MAA injection and imaging (in minutes). Results: A total of 139 ^{99m}Tc-MAA injections were performed in 112 patients. A median lung shunt fraction on planar scintigraphy of 5.5% (range 0.3-39%) was found. The ability of both measurements to differentiate between patients (the reliability) was moderate, as the intraclass correlation coefficient, $ICC_{consistency}$ (ignoring systematic error), was 0.72; the $ICC_{agreement}$ was 0.59. Planar scintigraphy overestimated the absorbed dose by a median of 1.4 Gy / GBq yttrium-90 (range -2.2 - 14.9 Gy) compared to SPECT/CT. On planar scintigraphy 4 cases exceeded the 30 Gy threshold. However, SPECT/CT did not agree in 1 case and identified 4 extra cases ineligible for treatment. Univariable analyses identified the following risk factors both on planar scintigraphy and SPECT/CT: angioinvasion, tumor burden, and time between ^{99m}Tc-MAA injection and imaging. Only planar scintigraphy showed an association between lung shunt and hypervascularity and extrahepatic disease. Conclusion: Planar scintigraphy overestimates lung shunting compared to SPECT/CT. A clinical significant threshold for lung shunting should be defined for SPECT/CT and may be used in combination with risk factors for accurate patient selection.

OP330

Previsional dosimetry based on 99mTc-MAA SPECT for radioembolization of liver lesions with 90Y-loaded microspheres: impact of attenuation correction, scatter correction and calibration

M. Pacilio[1], C. Chiesa[2], **M. E. Ferrari**[3], F. Botta[3], L. Lorenzon[1], M. Mira[2], M. Ljungberg[4], M. Cremonesi[3]; [1]Azienda Ospedaliera San Camillo Forlanini, Roma, ITALY, [2]Istituto Nazionale dei Tumori, Milano, ITALY, [3]European Institute of Oncology, Milano, ITALY, [4]Lund University, Lund, SWEDEN.

Background and aim: Therapy optimization in radioembolization (RE) with 90Y-loaded microspheres should be pursued through treatment planning based on 99mTc-MAA-SPECT image. The accuracy of the quantification depends on differen issues. The aim of this study was to evaluate the influence of attenuation and scatter corrections in the 99mTc-MAA-SPECT images for RE dosimetry of simulated patients and clinical cases. Methods: Simulated and real 99mTc-MAA-SPECT images were reconstructed by OSEM algorithm without corrections (NoAC_NoSC) or with scatter (NoAC_SC), attenuation (AC_NoSC), scatter and attenuation (AC_SC) corrections. Monte Carlo (MC) simulations (SIMIND code) were performed for three different body size

and different activity distribution (uniform activity in the whole liver, or in a liver lobe, or with hot lesions with lesions/normal liver ratio=5). 36 clinical cases were also studied with a relative calibration method. Lesions and healthy parenchyma were manually contoured on the co-registered CT-SPECT images. The absorbed dose distributions were calculated at dose level from the activity maps, comparing results obtained from different correction methods in terms of DVHs and dose profiles. For simulated cases, the dose image derived from the input activity map was the Gold Standard (GS) while for clinical cases, the dose map from AC_SC was considered as reference. Results: For simulated cases, differences vs. GS decrease implementing AC and SC in the tomographic reconstruction. Deviations from GS of D95%, D70%, D50% for lesion and healthy parenchyma are lower for AC_NoSC, than for NoAC_SC.In the clinical cases, deviations from GS of D90%, D70%, D50%, are lower for AC_NoSC, than NoAC_SC for lesions, while for healthy parenchyma the absence of attenuation correction is less critical than the absence of scatter correction.Conclusions:All corrections are needed to improve dosimetric accuracy.The difference in the results of the healthy parenchyma between simulations and real patients, as regards the influence of separate AC and SC, could be due to the influence of patient motion (respiration, not present in simulations) or variability of activity distributions in real patients.However, for the most important side of the planning strategy (safety=parenchyma dosimetry) the absence of attenuation correction (not available in all SPECT system) seems less critical than the absence of scatter correction (available on all system). Despite inaccuracies, the dosimetry approach provides a much safer (lower toxicity) and efficient (higher tumour irradiation) approach showing therefore a better RE optimization than using others empirical methods indicated by producers (BSA, tumor involvement, mean dose to lobe).

OP331

Effect of Data-Driven Respiratory Gating on Radioactivity Quantification in Liver Lesions for Pre-Radioembolization Tc-99m-MAA SPECT/CT

J. C. Sanders[1,2], A. H. Vija[3], T. Kuwert[1], P. Ritt[1]; [1]Clinic of Nuclear Medicine, University Hospital Erlangen, Erlangen, GERMANY, [2]Pattern Recognition Lab, University of Erlangen-Nuremberg, Erlangen, GERMANY, [3]Siemens Molecular Imaging, Hoffman Estates, IL, UNITED STATES.

Aims: In single photon emission-computed tomography (SPECT), comparatively long acquisition times may lead to blurring and underestimation of radioactivity in foci moved by respiration. This can be mitigated by respiratory gating, whereby a surrogate signal representing the patient's respiratory state is used to subdivide the data into gates, within which motion is assumed negligible. Individual gates can then be analyzed separately. The aim of this study was to examine the extent to which radioactivity in liver lesions varies after respiratory gating is applied. Methods: After granting informed consent to participate in the study, 7 patients (5M/2F) aged 64.9±5.8 Y were injected intraarterially with 143.7±43.5 MBq Tc-99m-MAA (microaggregated albulin) as part of our clinic's standard Y-90 radioembolization planning protocol. A SPECT/CT acquisition was then performed using a Symbia T2 (Siemens Molecular Imaging) with 60 views (15 sec each). List-mode data was acquired, and, using a fully-automated, data-driven gating method, a respiratory-gated dataset with 5 gates was generated in addition to the standard ungated dataset. Reconstruction was carried out with a research version of xSPECT Quant (20 iterations/1 subset). CT attenuation and scatter correction, but no post-smoothing, was performed. Magnetic resonance (MR) images were selected for each patient and co-registered with SPECT reconstructions. Using the MRs, volumes of interest (VOIs) were defined for each patient around lesions exhibiting tracer uptake. Within each VOI, the ratio R of activity in each gated reconstruction to that in the ungated reconstruction was then computed. Results: For 13 of the 16 VOIs assessed, R>1 for at least one gate, indicating underestimation of activity in the ungated reconstruction. Taking the maximum R for each lesion, the mean across all VOIs was 1.15±0.22. Taking the minimum, the mean was 0.82±0.10. For each lesion, the average deviation across all gates was 0.09±0.09. Conclusion: In this study, 81.3% of examined lesions showed underestimation in the ungated dataset, the average magnitude of which was 15%. This implies that blurring due to respiratory motion incurs a bias on ungated SPECT images. Variation across gates for each lesion was due to activity passing in and out of the static VOI as the patients breathed. Although not affecting the lung/liver shunt currently used for radioembolization planning, underestimation of tumor activity may have implications on future efforts to personalize therapy to maximize tumor dose. One limitation of the study is the small number of patients analyzed, which must be increased to reach a definite conclusion.

OP332

Feasibility and safety of selective internal radiation therapy (SIRT) procedure in one day

A. Dieudonné[1], A. Siebert[2], M. Abdel-Rehim[2], S. Legendre[1], S. Sebahoun[1], M. Ben-Reguiga[1], V. Vilgrain[2], R. Lebtahi[1]; [1]Department of Nuclear Medicine, Beaujon Hospital, Assistance Publique-Hôpitaux de Paris (APHP), Clichy, FRANCE, [2]Department of Radiology, Beaujon Hospital, Assistance Publique-Hôpitaux de Paris (APHP), Clichy, FRANCE.

SIRT procedures are usually performed in two steps separated by 7 to 14 days. Here we study the feasibility of performing the procedure in day. Methods: From a 5 years experience of SIRT, with 80 procedures, we had 4 cases for which a second pre-therapeutic angiogram was performed the same day than the therapeutic injection, followed by Tc-99m-labelled-macro-agregated-albumin-particles (MAA) injection. For these patients a second pre-therapeutic angiogram was programmed and new gastric arteries were identified and embolized. This was followed by the injection of MAA to re-evaluate the lung-shunt fraction, extra-hepatic uptake, the perfusion of the liver and the dosimetry of the tumor and non-tumoral tissues. Due to specific circumstances, this procedure was programmed the same day than the therapeutic injection. After 185 MBq intra-arterial injection of MAA, the patients were transferred to the nuclear medicine department for a SPECT/CT acquisition with the catheter in place. The images were analyzed during the transfer of the patient back in the interventional room for the microspheres injection that took 15 minutes. The microspheres (resin, SIRSPHERE, SIRTEX) were prepared and injected. The quality control of the microspheres injection by bremsstrahlung SPECT/CT (50-150 keV, MELP) was done the day after to avoid contamination of the Tc-99m peak. Results: For all 4 patients, no complication related to the transfer back and forth to the nuclear medicine department occurred. The time between the MAA and microspheres injection varied from 1 to 1,5 hours. The comparison of MAA and microspheres showed a very good agreement between MAA and microspheres, meaning that the presence of MAA in the micro-vessels does not perturb the perfusion of the microspheres and the injection of microspheres can be done 1 to 1,5 hours after the MAA injection.Conclusion: The “one day” SIRT procedure, done under specific circumstances, highlights the feasibility and safety of the process in term of patient management and the very good agreement between microspheres and MAA perfusion.

OP333

Regularized reconstruction results in a major improvement of Y-90 PET/CT image quality after SIRT with Y-90 microspheres

K. Tatsch[1], J. Touati[2], M. Leicht[1], C. Puskas[1], L. Maron[1], H. Arques Aguilo[2]; [1]Municipal Hospital Karlsruhe Inc, Dept. of Nuclear Medicine, Karlsruhe, GERMANY, [2]GE Healthcare, Buc, FRANCE.

Due to the physical properties of Y-90, Bremsstrahlung SPECT/CT images after SIRT are hampered by low quality. PET/CT scans might enhance image quality, however, due to the low count statistics based on the Y-90 inherent low positron emission decay, images acquired at reasonable scanning times for the patient are generally hampered by high noise levels. This study investigates whether an advanced reconstruction algorithm (regularized reconstruction aiming for full convergence; Q.Clear) can significantly improve image quality of Y-90 PET/CT scans following Y-90 SIRT therapy. So far we investigated the PET/CT (GE Discovery 710) Y-90 TOF-scans of 14 patients after radioembolization of liver tumors and metastases with Y-90 SIR-Spheres. Six different iterative reconstructions were performed: Standard (Std) with routine parameters for FDG scans (3 it, 24 sub, filter 6.4 mm, 256 matrix), 2 data sets reconstructed in a 192 matrix (8 it, 16 sub, filter 9 (V1) and 17 mm (V2)) and 3 data sets using Q.Clear (Q) with different beta values (750; 1000; 2000). All images were visually assessed by 4 readers (2 experts and 2 non-experts) with respect to 3 parameters: visual image quality, noise level and lesion detectability. Rating was based on a numeric scale from 1 (worst) to 5 (best). Rating for Image Quality was 1.4±0.3 for Std, 1.6±0.3 for V1, 2.4±0.3 for V2, 3.5±0.3 for Q.750, 4.0±0.3 for Q.1000 and 4.3±0.2 for Q.2000. Rating for Noise Level was 1.3±0.3 for Std, 1.6±0.3 for V1, 3.5±0.4 for V2, 3.0 ±0.3 for Q.750, 3.7±0.3 for Q.1000 and 4.6±0.4 for Q.2000. Rating for Lesion Detectability was 1.4±0.4 for Std, 1.6±0.3 for V1, 2.4±0.5 for V2, 3.6±0.4 for Q.750, 4.0±0.4 for Q.1000 and 3.9±0.4 for Q.2000. There was no statistical difference between expert and non-expert reads. Thus, in all three categories best results were obtained for Q.Clear reconstructions. Q.Clear data using a beta value of 2000 delivered the best trade off. Image quality of Y-90 PET/CT scans after SIRT can be dramatically improved by using Q.Clear, a regularized reconstruction algorithm aiming for full convergence. The very low noise levels achieved allow for an excellent delineation of the regional deposition of SIR-Spheres within the treated liver lobes or segments, which is a prerequisite for using such data for improved dosimetric calculations and comparisons with pre-therapeutic FDG and MAA scans. Currently patients are followed to additionally address whether these high quality scans may have impact on a better prediction of treatment response.

OP334

A branching artery tree model in concordance with microscopy observations of microsphere distribution in liver following radioembolisation

J. Högberg[1], M. Rizell[1,2], R. Hultborn[1,2], J. Svensson[1,2], O. Henrikson[1,2], J. Mölne[1,2], P. Gjertsson[2], P. Bernhardt[1,2]; [1]The Sahlgrenska Academy at The University of Gothenburg, Gothenburg, SWEDEN, [2]Sahlgrenska University Hospital, Gothenburg, SWEDEN.

Aim: Our previous investigations have demonstrated that large clusters of resin microspheres are common in normal liver tissue arteries after radioembolisation, causing more heterogeneity in the absorbed dose distribution than can be explained by depositions limited to the final arterioles. In order to reproduce microsphere-clustering findings, we constructed a hepatic artery branching tree

model. Materials and Methods: The virtual hepatic branching artery tree model consisted of a dichotomous (one vessel always branching into two vessels) branching artery of 20 generations. The inner artery diameter exponentially decreased from the lowest to the highest generation. Three variable parameters were optimised to obtain concordance between simulations and measured microsphere distributions: a combined artery coefficient of variation (ACV) for the inner diameter of all artery generations and the microsphere flow distribution at the nodes; a hepatic tree distribution volume (HDV); and an embolisation (EMB) parameter that reduces the artery diameters. The model was tested against previously measured activity concentrations in 16 biopsies, where the microsphere distribution was determined via light microscopy of 15 30-μm sections per biopsy (mean concentration, 14 microspheres/mg; distributions were divided into three groups with mean microsphere concentrations of 4.6, 14, and 28 microspheres/mg). Results: Optimisation of the simulations, by increasing microsphere concentrations and simultaneously increasing ACV and EMB and decreasing HDV (from 130 to 22 cm^3), demonstrated increasing cluster sizes in wider vessels with increasing microsphere concentration. Conclusion: Simulations revealed that microsphere clusters are larger and more common in volumes with high microsphere concentrations, thereby able to reproduce the distributions found in our previous microscopy investigations, the latter demonstrating that the absorbed dose distribution is more non-uniform for resin microspheres than what has been hypothesized or demonstrated by others. The non-uniform absorbed dose pattern for glass spheres is expected to depend mostly on high activity per microsphere, whereas microsphere clusters, caused by embolisation effects, are expected to be much more common for resin sphere treatments. The always relatively small and yet decreasing HDV with increasing microsphere concentration shows that our dichotomous branching model is a simplified model of a native hepatic branching artery tree, the latter demonstrated by anatomy studies to be much more complex than our model. Our model could be useful, though, when limited to small-scale analysis of specific liver segments where the mean absorbed dose within the segment is detected with Single-Photon Emission Computed Tomography (SPECT) or Positron Emission Tomography (PET).

OP335

Reconstruction, volumetry and dosimetry optimisation for 99mTc-SPECT and 90Y-PET images: towards reliable DVH for SIRT treatments

M. Bernardini[1], H. Thevenet[1], C. Berthold[2], A. Fischer[3], A. Petitguillaume[4], A. Desbrée[5], C. Smadja[1], P. Weinmann[1], N. Ghazzar[1]; [1]European Hospital Georges Pompidou, PARIS, FRANCE, [2]Gustave Roussy Institut, Villejuif, FRANCE, [3]Philips GmbH Innovative Technologies, Aachen, GERMANY, [4]Cancéropole Grand Sud Ouest, Toulouse, FRANCE, [5]LEDI, IRSN, Fontanay aux Roses, FRANCE.

Aim: Our purpose was to optimise image reconstruction and volumetric delineation on MAA-99mTc-SPECT/CT and 90Y-PET/CT images, in liver treatment with Selective Internal Radiation Therapy (SIRT), in order to improve dosimetry calculations. The prediction power of MAA-99mTc for 90Y-spheres treatments was also investigated as well as dose-effect relationship relating DVHs with patients follow-up. Materials and methods: To minimise errors in volumes delineation and quantification, 2 NEMA phantom studies were performed. 99mTc-MAA-SPECT/CT images were acquired with a hybrid gamma camera Infinia-Hawkeye (GE) and 90Y-PET/CT images with a Discovery 690 VCT-TOF (GE). Phantom optimisation results were applied to images of 10 patients treated with 90Y-SIR-spheres® (SIRTEX): treatment planning (99mTc-SPECT/CT), post-dosimetry (90Y-PET/CT) and dose-effect relationship (ceCT, 18F-PET/CT) were investigated via DVHs and isodoses. Dosimetry was based on kernel convolution (Imalytics, Philips). Results: 90Y and 99mTc phantom studies enabled to establish the reconstruction parameters that minimise errors in volumes and quantification for PET and SPECT images: optimised reconstruction and adaptive thresholding, allow decreasing average error in volumes from -64.3% to 2.2%. Using the "best volumes" on the "best quantification", here called "cross volumes" technique, allows decreasing error of mean concentration from -64.4% to -52.2% in average. Partial volume effect correction (PVC) decrease quantification error to -17.4% in average. For 90Y-PET images, optimising reconstruction parameters increase mean absorbed dose of +88.1% in average (from +21.0% to +235.9%, depending on volume). Applying PVC, mean absorbed dose increases of +70.9% in average (from +48.6% to 100.4% depending on volume). For 99mTc-SPECT images, optimising reconstruction parameters does not increase significantly quantification (maximum dose difference is -4,0%). With PVC correction, mean absorbed dose increase of +110% in average (from +74.2% to 162.8% depending on volume). These results were applied to analyse patient's images. Differences between lesions delineate on ceCT (pre-therapeutic image reference) and volumes threshold on 99mTc-SPECT and 90Y-PET, reach 320%. Intersections between volumes show important discrepancies too. Absorbed doses in 90Y-PET and 99mTc-SPECT volumes are higher than in ceCT lesions, pointing out the problem of targeting in SIRT. DVH establish a relationship between volume and dose, overtaking the inadequate information of mean absorbed dose. Conclusion: As mean absorbed dose does not represent the irradiation and radiobiological effects on lesions and organs at risk (parallel organs), DVH is essential to optimise treatment planning and to evaluate dose-response effect. To obtain reliable DVH, optimisation of volumes delineation is mandatory as errors in volumes can be important and the impact on dosimetry huge.

Assessing the impact of clinically certified NEP and/or ACE inhibitors on the in vivo profile of [111In-DOTA] MG11: A comparative study in mice

A. Kaloudi[1], E. Lymperis[1], E. P. Krenning[2], M. de Jong[2,3], B. A. Nock[1], **T. Maina**[1]; [1]Molecular Radiopharmacy, INRASTES, NCSR Demokritos, ATHENS, GREECE, [2]Institute of Nuclear Medicine, Erasmus MC, ROTTERDAM, NETHERLANDS, [3]Insitute of Radiology, Erasmus MC, Rotterdam, NETHERLANDS.

Aim: We have recently shown that treatment of mice with the neutral endopeptidase (NEP)-inhibitor phosphoramidon (PA) improves the bioavailability and tumor uptake of several radiopeptides. For the truncated gastrin radiotracer [^{111}In-DOTA]MG11 ([(DOTA)DGlu^{10}]gastrin(10-17)) this method led to impressively high tumor-to-kidney ratios. Translation of this concept in the clinic requires the use of clinically certified NEP inhibitors, such as thiorphan (TO) and its orally administered prodrug racecadotril (Race). On the other hand, both NEP and angiotensin converting enzyme (ACE) have been shown to participate in the catabolism of gastrin analogs. In the present study, we first compare the effects induced on the biological profile of [^{111}In-DOTA]MG11 during NEP inhibition by: i) PA (reference), ii) TO, or iii) Race. Furthermore, we investigated the role of ACE in the catabolism of the radiotracer employing the established ACE-inhibitor lisinopril (Lis). Materials and Methods: [^{111}In-DOTA]MG11 was co-injected with vehicle, or with PA (300 μg), or TO (150 μg), or Lis (100 μg), or Race (2 mg; 30-40 min in advance via ip injection). Mouse blood collected 5 min post-injection (pi) was analyzed by HPLC to assess catabolism rates. Biodistribution was performed at 4 h pi in SCID mice bearing AR42J xenografts after co-injection of [^{111}In-DOTA]MG11 with vehicle, or with PA, or TO, or Lis, or PA+Lis, or Race (ip pre-injected). Results: Treatment of mice with PA, TO or Race increased the levels of circulating [^{111}In-DOTA]MG11 from 5% to 70-75% at 5 min pi. During NEP-inhibition, tumor uptake impressively increased from 1.8 ±1.0%ID/g (controls) to 15.3±4.7%ID/g (PA) and 12.3 ±3.6%ID/g (TO), while with Race tumor values reached 6.8 ±2.8%ID/g. Conversely, Lis had no effect on tumor uptake and no additive effect when co-injected with PA. In all cases renal accumulation remained low and unaffected by any of the above inhibitors. Conclusions: This study has shown that ACE is not involved in the in vivo degradation of [^{111}In-DOTA]MG11, confirming NEP as the predominant degrading enzyme of the radiotracer. NEP inhibition with the clinically tested NEP inhibitors TO and Race resulted in significant enhancement of tumor-to-kidney ratios versus controls. The fact that TO, unlike its ip-administered prodrug Race, produced comparable effects with PA highlights the importance of sufficient NEP-inhibition for maximizing tumor targeting. Further studies, to optimize doses, administration routes and inhibitor-combinations, are currently in progress to advance translation of this concept into the clinic.

A phage display derived stabilised bicyclic peptide targeting MMP-14 shows high imaging contrast in small animal PET imaging

M. Eder[1], S. Pavan[2], U. Bauder-Wüst[1], K. van Rietschoten[2], L. Baldassarre[2], U. Schierbaum[3], O. Seibert[3], K. Leotta[3], S. Campbell[2], H. Harrison[2], C. Stace[2], E. Walker[2], U. Haberkorn[3], K. Kopka[1], D. P. Teufel[2]; [1]Radiopharmaceutical Chemistry, German Cancer Research Center, HEIDELBERG, GERMANY, [2]Bicycle Therapeutics Limited, Cambridge, UNITED KINGDOM, [3]CCU Nuclear Medicine, German Cancer Research Center, HEIDELBERG, GERMANY.

Aim: Radiolabeled bicyclic peptide scaffolds represent highly attractive molecules for PET imaging of various oncological entities and for therapeutic applications due to their low molecular weight, high affinity and specificity. In the present work, bicyclic peptides directed against the tumor associated matrix metalloproteinase 14 (MMP-14, MT1-MMP) were identified, preclinically characterized and further optimized with regard to their in vivo stability and their clinical potential as PET imaging agent. Materials and Methods: Thio-ether formation via the three reactive cysteines of a randomized amino acid sequence and fusion to the phage gene-3-protein generated a library of bicyclic peptides [1]. An affinity selection process yielded several binders with variants showing single digit nanomolar affinity and high specificity for MMP-14. The selected Bicycle structure offers the ability to alter properties through chemical modification and the addition of functional groups via linkers without affecting the affinity, for example a site-specific labelling with the radiochelator DOTA. This construct was radiolabelled with Ga-68 or Lu-177, respectively, and analyzed preclinically according to its cell binding and in vivo tumor-targeting properties. In order to further improve the pharmacokinetic and tumor targeting properties the Bicyclic peptide sequence was stabilized by chemical modification. Results: The initially selected compound DOTA-N144 already revealed high specificity and affinity (KD= 0.5 nM) as determined by fluorescence polarization competition assays. MALDI-TOF analysis of wild-type N144 in mouse plasma however indicated loop-opening potentially causing in vivo instabilities. Several targeted chemical modifications of the amino acid sequence led to a stabilised variant with retained

affinity and specificity. Organ distribution at 1 h p.i. of the optimal dose showed a significantly higher MMP14-specific tumor uptake of 12.02 ± 2.37 %ID/g (0.12 ± 0.06 %ID/g for non-binding scrambled variant) as compared to the non-stabilised compound (2.75 ± 0.88 %ID/g). Both compounds showed fast background clearance (<1 %ID/g for all organs except the kidneys) resulting in high imaging contrast in the μPET studies. Conclusions: The phage display selection of bicyclic peptides was shown to be a highly flexible and attractive strategy for generating and developing peptidic drug leads. The stabilised bicyclic DOTA-lead compound revealed MMP-14-selective tumor uptake in the xenograft model and rapid clearance from non-target crucial organs resulting in high imaging contrasts. The compound represents a highly promising radiotracer which could be used as radiopharmaceutical for future clinical PET imaging and radioendotherapy of MMP14-expressing tumors. Sometimes, Less is More: Specific Activity of Radiopharmaceuticals and its Impact on Biodistribution and Imaging Contrast

J. Notni[1], D. Reich[1], J. Pollmann[1], F. Hofmann[1], M. Weineisen[1], T. Kapp[2], F. Rechenmacher[1], H. Kessler[2], H. Wester[1]; [1]Pharmaceutical Radiochemistry, Garching, GERMANY, [2]Center for Integrated Protein Research, Garching, GERMANY.

For a fixed dose of a radiopharmaceutical (given in MBq), the specific activity A_S (e.g. in GBq/μmol), defined as radioactivity (A) divided by the total molar amount (n) of labelled and unlabelled precursor, is determining the overall injected dose of pharmacologically active compound (e.g., in mg/kg). Particularly for radiopharmaceuticals with saturable targets, such as receptors, the latter can have a pronounced effect on both target accumulation and general biodistribution, and therefore on imaging results. While this is a known and well-described phenomenon, its extent is often underestimated. Here, its manifestation is illustrated on examples of current PET-tracer development. TRAP-based trimers of a) cyclo(RGDfK), targeting αvβ3 integrins, b) an acyclic pseudopeptide, targeting α5β1 integrins, and c) a EuK-based ligand, targeting PSMA, were synthesized from the alkyne-functionalized monomers by one-pot click-chemistry (CuAAC) conjugation to a tris-azide-functionalized TRAP chelator. Affinities (IC50) were determined by ELISA on vitronectin/fibronectin (αvβ3/α5β1), or displacement assays on LNCaP cells (PSMA). Following fully-automated ^{68}Ga labelling, the compounds were administered to mice bearing M21 (integrins) or LNCaP (PSMA) xenografts, with specific activities ranging from 0.5 to 1500 GBq/μmol (approx. 35 nmol to 13 pmol for a 20 MBq injection), which underwent PET and ex-vivo biodistribution studies. Trimerization of the receptor ligands resulted in substantially increased target affinities (αvβ3: 220 pM, α5β1: 80 pM, PSMA: 2 nM) compared to the monomers (5, 2.3, and 36 nM, respectively). For all investigated tracers, variation of A_S resulted in dramatic changes in biodistribution and thus, tumor/organ and tumor/"background" ratios. For example, increasing the total dose of the α5β1-targeting TRAP-trimer Ga-Aquibeprin from 16 pmol to 6 nmol resulted in improved PET tumor/muscle ratio from 5.3 to 12.4. Likewise, for 20 MBq of the ^{68}Ga-labelled EuK trimer, lowering A_S from 540 to 20 GBq/μmol resulted in strongly declining kidney uptake from 28.7 to 3.2 %ID/mL, respectively, while LNCaP tumor uptake was just slightly decreased from 1.5 to 1.3 %ID/mL.Specific activity is an important factor in tuning the in-vivo properties of radiopharmaceuticals, allowing to improve tumor contrast and to manage specific uptake in other tissues. As such, it deserves more attention, particularly in view of substantial evidence for the fact that lower A_S (i.e., higher amounts of pharmacologically active compound) can improve addressing of tumors, while higher A_S can result in more detailed physiological target visualisation. Thus, we advocate for a more detailed investigation of this parameter in radiopharmaceutical studies.

OP339

Assessment of the specificity of 99mTc-duramycin in a mouse model of colorectal cancer

F. Elvas[1,2], C. Vangestel[1,2], K. Y. Pak[3], S. Stroobants[1,2], S. Staelens[1], L. wyffels[1,2]; [1]University of Antwerp - Molecular Imaging Center Antwerp, Wilrijk, BELGIUM, [2]University Hospital Antwerp - Department of Nuclear Medicine, Edegem, BELGIUM, [3]Molecular Targeting Technologies, Inc., West Chester, PA, UNITED STATES.

Aim: As most cancer therapies available have a pro-apoptotic and necrotic effect, the use of specific radiotracers allows for molecular imaging of cell death. Duramycin is a small peptide (MW~2kDa) that recognizes cell death by binding to the head group of phosphatidylethanolamine (PE) with high affinity. Recently, we showed the ability to image therapy-induced cell death in a mouse model of colorectal cancer using 99mTc-labeled duramycin(1). In the current study we aimed at assessing the specificity of 99mTc-duramycin for imaging cell death in chemotherapy treated tumor-bearing mice by performing a blocking study. Materials and Methods: Human colorectal cancer cells (Colo205) were subcutaneously inoculated in both hind legs of athymic nude mice. After the tumors reached 217 mm^3, baseline

static SPECT-CT scans were performed 4 h after injection of 99mTc-duramycin (36.0 ± 1.8 MBq). Chemotherapy consisted of a combination of 80 mg/kg irinotecan plus 5 mg/kg oxaliplatin (q.d. in alternate days during one week) or the corresponding vehicles for control mice (n=6 tumors/group). 99mTc-duramycin (35.0 ± 4.7 MBq) was intravenously injected 24 h after the last course of treatment, and following a 4 h radiotracer uptake-period animals underwent static SPECT-CT imaging. For blocking, duramycin (2 mg/kg as 0.8 mg/mL solution in saline) was injected 30 min before the radiotracer. Radiotracer uptake in the tumors was evaluated by SPECT (%ID/g/kg) and by γ-counting of the tumors (%ID/g). Cleaved caspase-3 (CC3) and TUNEL staining of the tumors will allow assessing cell death in the tumor. Results: On the SPECT images, tumors showed an increased accumulation of 99mTc-duramycin following combination chemotherapy (144.2 ± 19.1%ID/g/kg; $p<0.001$), compared to control (40.6 ± 2.8%ID/g/kg). The binding of 99mTc-duramycin was blocked by preinjection of nonlabeled duramycin (32.9 ± 9.7%ID/g/kg; $p<0.001$). In treated tumors the radioactivity in the tumors positively correlated to CC3 ($r=0.85$, $p<0.001$) and TUNEL ($r=0.81$, $p<0.001$) stainings. For the blocking, regional distribution of radioactivity in the tumors will be determined by autoradiography, and correlated to CC3 and TUNEL staining. Conclusion: Our results show that 99mTc-duramycin specifically accumulates in apoptotic tumors in response to therapy. 99mTc-duramycin holds promise as a radiotracer for early treatment evaluation with potential clinical usefulness in the setting of oncology. 1. Elvas F, et al. Characterization of [99mTc]Duramycin as a SPECT Imaging Agent for Early Assessment of Tumor Apoptosis. Molecular imaging and biology : MIB. Apr 21 2015. OP340

Development of radiocobalt-labeled GRPR antagonist NOTA-PEG2-RM26.

B. Mitran[1], Z. Varasteh[1], U. Rosenström[2], V. Tolmachev[3], G. Lindeberg[2], M. Larhed[4], A. Orlova[1]; [1]Preclinical PET Platform, Department of Medicinal Chemistry, Uppsala University, Uppsala, SWEDEN, [2]Organic Pharmaceutical Chemistry, Department of Medicinal Chemistry, Uppsala University, Uppsala, SWEDEN, [3]Biomedical Radiation Sciences, Immunology, Genetics and Pathology, Uppsala University, Uppsala, SWEDEN, [4]Science for Life Laboratory, Department of Medicinal Chemistry, Uppsala University, Uppsala, SWEDEN.

Aim: High GRPR expression is associated with numerous cancers including those of the prostate and breast. Bombesin (BN) analogues bind with high affinity to GRPR, having significant potential for radionuclide imaging and therapy of GRPR-expressing tumors. We have recently investigated a high-affinity antagonistic analog of bombesin (RM26) conjugated to NOTA chelator via a diethylene glycol (PEG2) spacer (NOTA-PEG2-RM26), labeled with 68Ga, 111In and Al18F. 68Ga-labeled NOTA-PEG2-RM26 showed favorable pharmacokinetic properties. However, as seen for 111In-NOTA-PEG2-RM26, the clearance of radioactivity from blood and receptor positive organs, combined with long retention in tumors resulted in higher tumor-to-background ratios at later time-points. The aim of the current study was to develop a 55Co-labeled PET agent to visualize GRPR. 55Co is a promising β+ emitting radioisotope, the 17.5 h half-life allowing transport to distant scanning centers and imaging at later time-points, when better contrast can be achieved. Materials and methods: The initial preclinical characterization of NOTA-PEG2-RM26 was performed using 57Co as a surrogate nuclide. Stability, in vitro binding specificity and cellular processing were analyzed. In vivo binding specificity and biodistribution were studied in NMRI mice. Results: NOTA-PEG2-RM26 was successfully radiolabeled with 57Co with yields exceeding 99% and demonstrated high stability under EDTA challenge. The radiopeptide showed retained binding specificity to GRPR in vitro. The internalization rate was very slow, internalized radioactivity fraction reaching 12% of cell associated radioactivity 24 h after incubation start. 57Co-NOTA-PEG2-RM26 biodistribution in mice was characterized by rapid clearance of radioactivity from blood (1.3±0.2% IA/g) and normal non-GRPR expressing organs and low liver uptake (0.65 ±0.05 % IA/g), 30 minutes after injection. The clearance was predominantly renal, with low degree of radioactivity reabsorption (6.4±1.9 %IA/g, 30 minutes p.i.). In vivo binding specificity studies showed a significant reduction of radioactivity uptake in GRPR expressing organs (pancreas, small intestines, and stomach) for mice co-injected with excess non-labeled peptide. Conclusions: The initial biological results suggest that radiocobalt-labeled-NOTA-PEG2-RM26 is a promising tracer for the visualization of GRPR-expressing tumors. The use of 55Co as label might provide a probe for PET imaging.

OP341

^{68}Ga-RM2 for imaging of prostate cancer - Successful implementation of Synthesizer- and Kit-based production methods

M. Zerna, A. Müller, **M. Berndt**; Piramal Imaging, Berlin, GERMANY.

Aim: Prostate cancer (PCa) is the most common cancer in men and the second most common cause in cancer-related deaths. Current diagnostic methods are limited in the accurate detection of primary prostate cancer. ^{68}Ga-RM2 is a nona-peptide with optimized binding sequence for Gastrin Releasing Peptide receptor (GRPr) which is overexpressed in prostate cancer. ^{68}Ga-RM2 has been identified from initial clinical studies as a potential imaging agent for detection of primary prostate cancer with high

specificity due to its low uptake in normal prostate and in benign hyperplasia. In order to support the ongoing systematic clinical exploration of ^{68}Ga-RM2 and its ability to improve pre-treatment risk-assessment and therapy-planning, robust GMP compliant manufacturing methods are needed using automated synthesizers and "ready-to-use" lyophilized kits. Herein, we report on our work in establishing a robust automated synthesis of ^{68}Ga-RM2 which could be further simplified to a "shake-and-bake" method. Materials and Methods: ^{68}Ga was obtained from an IGG100 generator (Eckert&Ziegler). Automated production was performed on a PharmTracer module (Eckert&Ziegler) using sterile cassettes, pre-filled RM2-precursor vials (ABX) and a Ga-labeling reagent kit (ABX/Eckert&Ziegler). The ^{68}Ga-generator eluate was trapped on a cation exchange cartridge. This cartridge was eluted with 5M NaCl + 5.5M HCl into the reaction vial, filled with RM2-precursor, sodium acetate solution and scavenger. After labeling at 100-110°C, buffered saline was added and the mixture was passed through a C18 cartridge. After washing the cartridge with buffered saline, ^{68}Ga-RM2 was eluted with ethanol (50%) and diluted with buffered saline. The influence of scavengers was investigated, as well as a process without the C18 cartridge purification. In a second approach, a "shake-and-bake" kit preparation was established. The ^{68}Ga-generator eluate was added directly into a vial containing RM2-precursor, sodium acetate and scavenger. The vial was heated and optionally buffer was added for pH-adjustment. Results: The automated synthesis provided up to 850 MBq of ^{68}Ga-RM2 in >70% uncorrected yield in 20min including purification and formulation. The radiochemical purity was >97% (HPLC and TLC) if ascorbic acid was used as scavenger. Without C18 cartridge purification, ^{68}Ga-RM2 was obtained in 14min in >76% uncorrected yield and purity of >95%. The simple and easy to use "shake-and-bake" kit approach provided ^{68}Ga-RM2 in 90% uncorrected yield and purity of >95%. Conclusion: ^{68}Ga-RM2 can be reliably manufactured on automated synthesizers as well as by a simple "shake-and-bake" kit strategy. Both methods provided ^{68}Ga-RM2 in high yields and high radiochemical purity.

OP342

Kit formulation, preclinical evaluation and experimental radionuclide therapy using CCK2 receptor targeting cyclic minigastrin

E. von Guggenberg[1], C. Rangger[1], L. Balogh[2], Z. Pöstényi[2], D. Pawlak[3], R. Mikołajczak[3]; [1]Department of Nuclear Medicine, Innsbruck Medical University, Innsbruck, AUSTRIA, [2]"Frédéric Joliot-Curie" National Research Institute for Radiobiology and Radiohygiene (NRIRR), Budapest, HUNGARY, [3]Radioisotope Centre POLATOM, National Centre for Nuclear Research, Otwock, POLAND.

Aim: Radiolabelled cyclic minigastrin analogues belong to the most promising candidates for possible clinical application in diagnosis and therapy of cholecystokinin-2 receptor (CCK2R) expressing tumours, mainly medullary thyroid cancer (MTC) and small cell lung cancer. Within an international collaboration of the IAEA we have developed and preclinically evaluated specific kit formulations for Tc-99m and Lu-177 labelling of two cyclic minigastrin analogues, HYNIC/DOTA-cyclo[γ-D-Glu-Ala-Tyr-D-Lys]-Trp-Met-Asp-Phe-NH2 (HYNIC/DOTA-cyclo-MG1) and HYNIC/DOTA-cyclo[γ-D-Glu-Ala-Tyr-D-Lys]-Trp-Nle-Asp-Phe-NH2 (HYNIC/DOTA-cyclo-MG2). Materials and methods: Two different lyophilized kit formulations were prepared for HYNIC- and DOTA-peptides. The stability during storage and after radiolabelling was examined at different time points. Cell uptake studies were performed in A431 human epidermoid carcinoma cells stably transfected with the human CCK2R (A431-CCK2R) and mock transfected cells (A431-mock). The biodistribution in xenografted mice (5 animals per group) was studied up to 24 hours (Tc-99m) and 7 days (Lu-177). An experimental radionuclide therapy (6 animals per group) was carried out with 177Lu-DOTA-cyclo-MG1 and 177Lu-DOTA-cyclo-MG2 at the dose level of 15 and 30 MBq. A dog with histologically confirmed MTC underwent diagnostic imaging and radionuclide therapy with HYNIC/DOTA-cyclo-MG1. Results and conclusion: The kit formulations displayed a high stability during storage. The radiochemical purity (RCP) at a specific activity >100 GBq/μmol resulted to be >90% for both 99mTc-labelled HYNIC-peptides, >93% for 177Lu-DOTA-cyclo-MG1 and >98% for 177Lu-DOTA-cyclo-MG2. The RCP of the 99mTc- and 177Lu-labelled peptides remained stable for 4 h and declined to ~95% (177Lu-DOTA-cyclo-MG2) and ~90% (177Lu-DOTA-cyclo-MG1) at 24 h after preparation. Cell uptake studies in A431-CCK2R cells confirmed a high receptor-specific cell internalization (>20% at 2 h after incubation). Biodistribution studies in xenografted mice revealed a tumour uptake of >3% ID/g for Lu-177 (4 h p.i.) and Tc-99m (1 h p.i.) and a tumour to kidney ratio of ~2 (Tc-99m) and ~3 (Lu-177). In the 15 MBq-group the mean tumour volume doubling time was 1.8 (A431-CCK2R) and 1.2 (A431-mock) times higher than in the untreated control group. For the 30 MBq-group these values resulted to be 2.6 (A431-CCK2R) and 1.7 (A431-mock). SPECT/CT imaging with 99mTc-HYNIC-cyclo-MG1 in a dog confirmed local recurrence of MTC. The first treatment with 177Lu-DOTA-cyclo-MG1 was well tolerated. All together the obtained results are promising for a potential clinical application in patients.

OP343

Development & application of an [18F] anti-amyloid peptide radiotracer

O. Morris[1], J. Gregory[1], A. Blykers[2], D. Allsop[3], M. Taylor[3], S. Allan[1], A. McMahon[1], H. Boutin[1], C. Prenant[1]; [1]The University of Manchester, Manchester, UNITED KINGDOM, [2]Vrije Universiteit Brussel, Brussels, BELGIUM, [3]The University of Lancaster, Lancaster, UNITED KINGDOM.

Aim: Development and automation of novel [18F] radiochemistry and its application in site-specifically radiolabelling an amino(oxy)-functionalised anti-amyloid peptide (RI-OR2) for use as an early-stage Alzheimer's Disease (AD) radiotracer.AD is a neurodegenerative disorder characterised by a progressive decline in cognitive function. AD pathology is identified by the formation of plaques, abnormal peptide clusters, mainly comprising fibrillar β-amyloid (Aβ). Plaques deposition leads to impaired synaptic transmission giving rise to the expression of the recognised cognitive symptoms.RI-OR2 is a novel brain-penetrant retro-inverso peptide inhibitor of an Aβ oligomer sequence. It has been reported to reduce amyloid deposition, associated oxidation and inflammation whilst also having a marked stimulatory effect on neurogenesis. This thereby demonstrates its potential therapeutic application. The retro-inverso D-amino-acid sequence confers high resistance to proteolysis and in-vivo stability to the RI-OR2. Unlike currently used AD radiotracers, RI-OR2, presents as an interesting PET probe owing to its ability to bind to early-, rather than late-, stage amyloid aggregates. In so doing, this might permit detection of AD early in disease onset, allowing more effective therapeutic intervention.RI-OR2 has been functionalised with an amino(oxy) functional group, permitting site-specific radiolabelling with the water-soluble prosthetic group, 2-[18F]fluoro-3-pyridinecarboxaldehyde.Materials & Methods: 2-[18F]Fluoro-3-pyridinecarboxaldehyde was produced by [18F]fluorination of 3-carboxaldehyde-N,N,N-trimethylpyridine-2-aminium bromide, obtained from 2-bromopyridine-3-carboxaldehyde. The 18F-prosthetic group was purified using SPE and reacted with amino(oxy)-RI-OR2, in aqueous conditions. The chemical identity of 2-[18F]Fluoro-3-pyridinecarboxaldehyde was determined by comparing its chromatographic properties with those of the standard 2-Fluoro-3-pyridinecarboxaldehyde.Results: 2-[18F]Fluoro-3-pyridinecarboxaldehyde was produced on a GE-Tracerlab FXFN within 40 min. achieving RCY of 80% ± 5% (n=5). Preliminary results show incorporation of the prosthetic group into the RI-OR2 achieving RCY of 40% ± 5% (n=3) within 30 min., as confirmed by SE-HPLC. 18F-labelled peptide was purified using SE-HPLC, RCP of >95% was obtained. In-vitro stability tests have been performed and preliminary study of the in-vivo biodistribution of this radiotracer has been performed in wild type pre-clinical models. Conclusion: We hereby present a novel [18F] radiolabelling technique of RI-OR2 using an [18F] water-soluble prosthetic group. Site-specific radiolabelling of RI-OR2 with 2-[18F] Fluoro-3-pyridinecarboxaldehyde is efficient, high yielding and proceeds under mild conditions. Optimisation of RI-OR2 radiolabelling and pre-clinical investigation of the 18F-labelled peptide in AD animal models (APPswe/PS1ΔE9 transgenic mice) is in progress and results will be shown.

Ga-68 macroaggregated albumin (MAA) Perfusion PET/CT for lobar pulmonary function quantification: comparison with anatomic method, volumetric CT and planar scintigraphy.

P. Le Roux, T. Leong, S. A. Barnett, R. J. Hicks, P. Eu, J. Callahan, R. Manser, M. S. Hofman; Peter MacCallum Cancer Centre, Melbourne, AUSTRALIA.

Aim: Patients with lung cancer and borderline pulmonary function should have preoperative evaluation of predicted postoperative residual lung function according to the European clinical guidelines (ERS and ESTS) to determine suitability for radical therapy. Several methods are currently used including anatomic estimation based on counting the number of segments to be removed, planar perfusion scintigraphy or volumetric CT. Pulmonary perfusion PET/CT can be performed by substituting labeling of macroaggregated albumin (MAA) with Ga-68 for Tc-99m. The aim of this study was to compare lobar function computed with PET-CT and the conventional methods. Materials and methods: Twenty two patients with lung malignancy and lung function impairment (mean FEV1 1.93L ± 0.67, mean DLCO 73 ± 21% predicted) underwent respiratory gated (4D) PET-CT lung perfusion scans after injection of approximately 50MBq of Ga-68 MAA. Lobes were delineated on CT images and segmentation was subsequently applied to the PET images to determine lobar perfusion (MIM version 6.3 software). Bland-Altman statistic was used to calculate agreement between the lobar lung function in the lobe with tumour using PET compared to anatomic estimation based on counting the number of segments (anatomic method), volumetric CT, and planar perfusion scintigraphy. Scintigraphy was not available in 6 patients. Results: Bland-Altman bias of PET compared to the anatomic method, volumetric CT and planar scintigraphy was -2.3 ± 7.3, -2.9 ± 4.6 and -1.6 ± 9.0, respectively. For some patients with tumors resulting in distal vascular obstruction or severe emphysematous change, there was major disagreement between anatomic and functional methods. The absolute difference between PET versus anatomic method, volumetric CT and planar scintigraphy was higher than 5% of global lung function in 11/22 patients, 8/22 and 13/16 patients, respectively. The difference was greater than 10% in 5, 1 and 6 patients, respectively. Conclusions: Lobar lung function computed with Ga-68 MAA PET lung perfusion imaging differs significantly in some patients from anatomical, CT and planar scintigraphy methods. Further studies are needed to assess if perfusion PET allows better prediction of postoperative lung function and may influence management of lung surgery patients.

OP352

The Importance Of Scintigraphic Pattern in the Suspected Diagnosis Of Sjögren's Syndrome.

B. Garcia-Garcia, M. J. Ribelles, E. F. Guillén, L. Sancho, M. Rodriguez, M. J. García-Velloso, P. DeCastro, E. Ornilla, J. Á. Richter; Clinica Universidad de Navarra, Pamplona, SPAIN.

AIM: To estimate the diagnostic contribution of Technetium 99m pertechnetate salivary gland scintigraphy (SGS) in referred patients due to suspicion of Sjögren's Syndrome (SS). The association among the degree of involvement shown by SGS, antibodies, biopsy result, and final diagnosis, was evaluated. MATERIALS AND METHODS: 87 SGS were performed in 84 subjects, who were sent from different specialty physicians (Neurology, Internal Medicine, and Rheumatology). All the patients underwent scintigraphy using a standardized protocol that included a sequential acquisition of images (1 minute/frame) and a salivary stimulation with citric acid 30 minutes later. Curves and glandular uptake were assessed qualitatively. Regarding the number of affected glands (n), four scintigraphic patterns were stablished: P-I (n=0), P-II (n=1), P-III (n=2), and P-IV (n≥3). Salivary gland biopsy was made in 19 patients, and ANA/ENA antibodies in 75. SS final diagnosis was confirmed in 23 cases, as stated in the American-European Consensus Criteria (AECC). RESULTS: Gland biopsy was positive in 9 patients (7 of which showed an altered uptake in SGS) and negative in 4 patients. Nevertheless, 6 samples got inconclusive results. ANA/ENA antibodies were detected in 42 cases, and negative in 33. Normal scintigraphic uptake was pointed out in 20 subjects, and abnormal patterns were reported in 67: 13 P-II, 26 P-III, and 28 P-IV. In relation to the final diagnosis, SGS globally depicted 84.6% sensitivity, 26.2% specificity, 32.8% positive predictive value (PPV), and 80% negative predictive value. These results were respectively modified by the four aforementioned uptake patterns. P-II: 33.34%, 66.67%, 20%, and 80%. P-III: 63.6%, 42.1%, 24.14%, and 80%. P-IV: 76.5%, 51.6%, 46.4%, and 80%. Assuming the antibodies presence as reference value, SGS result showed coincidence in 39 subjects, supporting or discarding SS diagnosis. There were discordant results in 36 patients: 21 of them were considered false-positive scintigraphy, 14 of which maintained antisialogogue therapy; 9 were false-negative scintigraphic cases, 3 referred previous sialoadenitis, 2 got a false-negative result for antibodies, and there was 1 patient lost. CONCLUSION: SGS is a useful diagnostic tool for the diagnosis of SS. Its performance improves significantly according to the number of affected glands. When interpretating SGS results in suspected SS, we may need to consider the coexistence of other

circumstances which could modify salivary secretion, particularly the concurrence with antisialogogue drugs.

OP353

Surgical planning issues of radio-guided sentinel node biopsy (SNB) in patients (pts) with second primary ipsilateral breast cancer (SPIBC)

C. Peterle, C. Cittanti, P. Carcoforo, M. Portinari, V. de Cristoforo, I. Santi, S. Panareo, L. Feggi; S. Anna University Hospital, Cona (FE), ITALY.

Background: Widespread of breast-conserving surgery and the boost of life expectancy in these pts contribute in increasing the number of women with SPIBC who have to undergo second radio-guided SNB.The aim of this retrospective study was to assess incidence and sites of possible altered lymphatic drainage in pts who underwent SNB for SPIBC and its impact in the increasing percentage of due conversion of the surgical treatment from local anaesthesia to general anaesthesia.MethodsWe re-evaluated all data about pts who underwent lymphoscintygraphy(LS)for detection of SNB since October 2012 to March 2015, dealing separately with pts with SPIBC:all of them had previous breast-conserving surgery,with either SNB or SNB followed by axillary lymph-node dissection(ALND).The day before surgery we injected the tracer(Nanocoll® 70MBq)with periareolar intradermal technique(PA)if the surgeon was planning to remove SN only in local anaesthesia,whereas intra and peritumoral injection(IPT)was used if the surgeon was planning to remove simultaneously SN and breast cancer.We considered SN in abnormal lymphatic drainage basin all the SN located in sites other than ipsilateral axilla.We dealt separately with non-identified SN.ResultsIn our NM Unit SN lymphoscintigraphy was performed on 745 pts:722 to detect SN for primary breast cancer;23 because affected by SPIBC(3.09%).No SN was visualized in 8/722 pts(1.11%),while in 1 pt SN was not in the ipsilateral axilla(1/722;0.14%).Among the 23 pts with SPIBC,in 6 pts(26.1%)SN was not found neither by LS nor during surgery by gammaprobe(all these pts previously underwent ipsilateral complete ALND);at least one SN was removed in 17/23 pts.The SN was found in ipsilateral axilla in 10/17 pts(58.82%:1 IPT;9 PA);in abnormal site in 7/17 pts(41.18%):contralateral axilla 3/17 pts(17.65%: 1 IPT, 2 PA);internal mammary 3/17 pts(17.65%:1 IPT,2 PA);anterior subcostal site 1/17 pts(5.88% PA).19/23 pts underwent surgery in local anaesthesia(82.6% PA),while 4/23 pts in general anaesthesia(17.4% IPT).In 3/17 pts(17.6%),in order to remove the LS-located SN in deep sites,it became necessary to delay surgery to convert from local to general anaesthesia.In one case (anterior subcostal site) SPECT-CT was necessary to locate SN during preoperative LS. Conclusions: This preliminary study shows that surgical planning(based on LS and SPECT-CT results)is critical in SPIBC pts(compared to not previously operated pts),being higher the percentage of SN non-visualized or in abnormal site,which require general anaesthesia(26.1% vs 1.11%;41.18% vs 0.14%:p<0,01).In pts who already underwent ALND,as expected,the rate of SN detection is significantly reduced,thus leading to ineffective surgery.

OP354

Factors influencing brown fat activation in FDG PET/CT: a retrospective analysis of 21,000+ cases

J. Steinberg, E. Vegt; Netherlands Cancer Institute, Amsterdam, NETHERLANDS.

Aim: Brown fat, or brown adipose tissue (BAT), is known to exhibit high uptake of ^{18}F-fluorodeoxyglucose (FDG) on positron emission tomography (PET), and can either be mistaken for malignancy or obscure underlying malignancy. BAT activation is associated with age, body mass index, gender, and ambient temperature. Nuclear medicine physicians have sought ways to reduce BAT activation, such as the administration of diazepam prior to injection of FDG, which is thought to decrease BAT activation via a reduction in sympathetic activity. The goal of this study was to gain further insight into the relative contribution of factors that may influence the activation of BAT. Materials and methods: A retrospective study of FDG PET/CT scans was performed using a database of PET/CT reports of 21,326 patients through the years of 2007-2014. The report contains information regarding the date and time of the scan, the age and gender of the patient, observed BAT activation, and the administration of diazepam. The date of the scan was used to determine average outdoor temperatures using data from that National Climatic Data Center (Asheville, North Carolina, United States). The data were analyzed using software developed in-house. Results: The number of patients with BAT activation was 864 (4.1%). BAT activation was observed to be higher in women than in men (6.2% vs. 1.6%, $p < 0.0001$), higher in patients under 60 years old than over 60 years old (6.6% vs. 1.9%, $p < 0.0001$), higher when average outdoor temperatures were below 10°C than above 10°C (4.8% vs. 3.4%, $p < 0.0001$), and higher for FDG injections in the morning than in the afternoon (4.6% vs. 3.3%, $p < 0.0001$). Diazepam usage was associated with much higher BAT activation (14.1% vs. 2.7%, $p < 0.0001$), among both genders, all ages, and outdoor temperatures. Conclusion: This large retrospective study provides more insight into the relative importance of several factors known to influence BAT activation. Using this information, additional measures can be taken to reduce BAT activation among high-risk individuals during FDG PET examinations. However, contradictory to

our expectation, we observed much higher BAT activation in patients who had received diazepam before the scan. This suggests that diazepam increases the likelihood of BAT activation, but it may also be due to the fact that patients at increased risk of BAT activation were selected to receive diazepam. More prospective studies are warranted to elucidate this finding.

OP355

Role of HIF-1 in Hypoxia Stimulated Glucose Metabolism in Human Endothelial Cells

J. Paik[1], j. Park[2], K. Jung[3], K. Lee[4]; [1]samsung medical center, seoul, KOREA, REPUBLIC OF, [2]samsung medical center, sungkyunkwan university, seoul, KOREA, REPUBLIC OF, [3]Samsung medical center, Sungkyunhwan University, seoul, KOREA, REPUBLIC OF, [4]samsung medical center, Samsung medical center, Sungkyunhwan University, seoul, KOREA, REPUBLIC OF.

Aim-Hypoxia is a common denominator of many vascular disorders and can profoundly affect endothelial function and metabolism. In this study, we evaluated the effect of oxygen depletion on endothelial 18F-FDG uptake, GLUT1expression and hexokinase activity, and investigated the role of HIF-1α in this response. Methods and Results— Human umbilical vein endothelial (HUVE) cells under normoxia, hypoxia, and reoxygenation were evaluated for 18F-FDG uptake, hexokinase activity, and Western blot analysis of GLUT1 and HIF-1α protein. The role of HIF-1α in hypoxia-stimulated 18F-FDG uptake was assessed by stabilization with a HIF-1α inhibitor. In addition, the effect of HIF-1α in hypoxia-stimulated HUVE cells was measured by 18F-FDG uptake and HIF-1α expression level with HIF-1α siRNA transfection and HIF-1α inhibitor. Furthermore, HIF-1α activation in hypoxic HUVE cells was assessed by HIF-1α transcription factor assay. Involvement of potential signaling pathways was investigated with respective protein kinase inhibitors. Exposure to hypoxia for 6 and 16 hr increased HUVEC 18F-FDG uptake to 181.0 ± 9.1% and 196.4 ± 1.1% of controls, respectively. Reoxygenation after 16 hr hypoxia gradually recovered 18F-FDG uptake to 4 hr. Hypoxia also induced a 3.9 ± 0.7 fold elevation of hexokinase activity, and a significant increase in GLUT1 and HIF-1α levels. HIF-1α stabilization with DMOG was sufficient to sustain hypoxia-stimulated 18F-FDG uptake during reoxygenation and to increase 18F-FDG uptake in normoxic conditions. Hypoxic HUVE cells significantly increased HIF-1α activation using transcription factor assay to 2.51 ± 0.02 fold elevation of controls. HIF-1α was activated by hypoxia and inhibition of the protein with HIF-1α siRNA and HIF-1α inhibitor completely abrogated the ability of hypoxia to increase HIF-1α and FDG uptake. Cycloheximide, tyrosine kinase inhibition with genistein, and protein kinase C (PKC) inhibition with staurosporine completely abolished hypoxia-stimulated FDG uptake by inhibiting HIF-1α increase. PI3 kinase inhibition with wortmannin blocked hypoxia-stimulated FDG uptake, not by inhibiting HIF-1α increase but by attenuating HIF-1α transcription activity. Conclusions— Hypoxia enhances endothelial cell glucose uptake by upregulating hexokinase activity and GLUT1 expression. The findings further indicate that HIF-1α plays a central role in this metabolic response with dependence of its increase on PKC and transcription activity on PI3K activities. Our findings provide a molecular basis for the mechanism in which ECs respond to acute hypoxia. The results of this study suggest that cross-talk between AMPK and Akt is essential for angiogenesis under conditions of hypoxic stress, but dispensable for angiogenic cellular responses in normoxic endothelial cells.

OP356

Initial Experience with PET/MRI in the Evaluation of Diabetic Foot

D. Franceschi, K. Yaddanapudi, R. Matthews, V. Brunetti, B. Martin; SUNY at Stony Brook, StonyBrook, NY, UNITED STATES.

INTRODUCTION: Osteomyelitis is a common complication of diabetic foot Infections. Accurate diagnosis of bone involvement in the setting of complicated diabetic foot is a diagnostic challenge. We present our initial experience with FDG PET/MRI to determine bone involvement in diabetic patients with chronic foot infection. MATERIAL AND METHODS: Seven patients with chronic foot infection and clinical suspicion of osteomyelitis underwent PET-MRI of the foot. The MR imaging findings were graded as Grade 0 – normal signal, Grade I - hazy reticulated, T1 hypointense signal, Grade II - confluent T1 hypointense signal. Grade II, confluent signal was considered diagnostic of osteomyelitis. Reticulated signal was believed to reflect edema on MRI. Abnormal focal increased FDG uptake localizing to the bone on fused PET-MRI images was considered as osteomyelitis. Five of the seven patients subsequently underwent surgery. Two patients diagnosed with osteomyelitis refused surgery and opted for conservative therapy. RESULTS: All seven patients had osteomyelitis according to PET- MRI findings. Five patients had osteomyelitis on histopathology and 2 patients according to secondary clinical end points. Three cases with FDG

uptake involving the bone on fused images had negative MRI patterns (Grade I reticulated T1 hypointense signal or no signal change). All the cases positive on MRI were positive on FDG-PET. The sensitivity of PET-MRI to diagnose osteomyelitis was 100% in this small series of diabetic patients with chronic foot infection. CONCLUSIONS: PET-MR proved to be highly sensitive modality with high reader confidence for diagnosis of osteomyelitis in diabetic foot infections, reflecting complimentary nature of these modalities.

Scatter correction requirements for quantitative I-131 SPECT: Triple Energy Window and full Monte Carlo correction compared in phantom acquisitions

C. A. J. van Gils[1,2], R. van Rooij[1], C. Beijst[1], H. W. A. M. de Jong[1]; [1]University Medical Center Utrecht, Utrecht, NETHERLANDS, [2]St. Antonius Ziekenhuis, Nieuwegein, NETHERLANDS.

Aim: For accurate dosimetry in I-131 therapy, reliable quantitative SPECT reconstructions are essential. However, due to the complex emission spectrum of this isotope, accurate scatter correction is not trivial. Especially downscatter from higher energetic 606 keV gamma emissions in the 364 keV photopeak energy window poses a challenge. The goal of this research is to compare the effectiveness of two different scatter correction methods, namely triple energy window (TEW) and full Monte Carlo scatter correction. By doing this, scatter correction requirements for performing quantitative I-131 SPECT can be derived. Materials and methods: A NEMA IEC body phantom is used in which the two largest of the six fillable spheres contain non-radioactive water, whereas the other spheres contain I-131 solution in an activity concentration ratio of approximately 10:1 compared to the background compartment. Acquisitions are performed using a Siemens Symbia T16 utilizing the HE collimator over 120 angles. Total acquisition duration is varied to investigate the influence of noise and activity on the scatter correction performance. Using the in house developed and validated reconstruction software Utrecht Monte Carlo System (UMCS), reconstructions are generated without scatter correction, with TEW scatter correction and with full Monte Carlo-based scatter correction. All methods use OSEM reconstruction with 8 subsets with varying number of iterations (1-40). The resulting data is analyzed along the NEMA NU 2-2007 guidelines, calculating hot- and cold-sphere contrast, as well as the percentage of background variability and the residual count error in the lung insert. Results: As expected, applying no scatter correction yields the poorest results in all measured parameters. The TEW correction method results in overestimation of scatter contribution in the photopeak window, leading to erroneous quantification and unrealistically high recovery coefficients. Monte Carlo scatter calculations on the other hand provided validated, accurate scatter corrections, regardless of object geometry and scan duration and resulted in a significant improvement of all measured parameters over no scatter correction. Conclusion: Scatter correction is important in accurate I-131 quantification. Conventional TEW correction can yield overestimations of scatter, potentially leading to consequent underestimation of total uptake and apparent increase in hotspot uptake in clinical scans. Therefore, extra caution should be exercised when using TEW correction for quantification purposes. Full Monte Carlo calculations provide object-specific scatter corrections leading to the most accurate quantification. Therefore, it is considered the method of choice for quantitative I-131 SPECT.

OP358

Absolute quantification in SPECT - a phantom study

J. Kupferschlaeger, J. Lott, L. Kuenzel, H. Dittmann, C. la Fougère; University Hospital Tuebingen/Department of Radiology/ Division of Nuclear Medicine, Tuebingen, GERMANY.

Aim: New software solutions like Q.Metrix® (GE Healthcare) promise absolute quantification of SPECT data using attenuation-, scatter correction and resolution recovery. Aim of this study was to investigate the accuracy of quantification as well as scatter correction, the determination of recovery coefficients (RC) for partial volume correction (PVC), the influence of CT high voltage (HV) and tube current on quantification. Material and methods: IEC-Phantom with Hot-Sphere-Insert (6 hollow spheres with diameters 10-37mm) and lung insert was filled with 99m-Tc for three lesion to background ratios (LBR): LBRinf (1:0), LBR4 (4:1), LBR8 (8:1). All measurements were performed on a Discovery 670 NM/CT PRO® (GE) SPECT/CT system. For each LBR we performed CTs with 3 HV-settings (140kVp, 120kVp, 100kVp) and for each HV three tube-current settings (10mA, 30mA and 75mA, rotation time 0.8 sec). Reconstruction was performed with OSEM algorithm (2i10s, no pre- and postfiltering) including scatter-, CT-based attenuation correction and resolution recovery. For quantification we used the following VOIs: 2 VOIs in the phantom background, 6 VOIs for the spheres using threshold segmentation, 2 cylindrical VOIs in the (cold) lung insert and a VOI for the whole phantom. For each VOI we determined

average and maximum activity concentration in Bq/ml. Results: CT HV and tube current has minor influence on quantification: we observed a maximum deviation less than 1.6% from the activity concentrations using a reference CT (120kVp, 75mA) for attenuation correction. The total activity in the phantom as well as the activity concentration in the background could be reproduced excellently with a maximum error of 5%. Resolution recovery improves the recovery for volumes larger than 5 ml by approx. 20% but was limited for volumes smaller than 5 ml. Maximum values from the VOIs tend to be overestimated (RC-range 1.0 to 1.5 for large volumes) depending on iteration parameters and the LBR. Average values depended on VOI type and accurate VOI-placement. The smallest two spheres (10mm, 13mm) could hardly be quantified or detected for LBR8 and LBR4. Scatter correction underestimates the scatter fraction: about 50% of the background activity concentration was found in the cold lung insert. Conclusions/Discussion: Absolute quantification of SPECT data using the Q.Metrix® software is possible if all corrections are applied. This is valid for large structures like organs but PVC should be applied for quantification of small lesions. Further improvement of scatter correction is needed.

OP359

Absolute quantification in a commercial SPECT/CT: Tc-99m Activity recovery in NEMA/IEC and anthropomorphic phantoms.

S. Gnesin[1], P. Leite Ferreira[2], J. Malterre[2], J. Prior[2], F. Verdun[1]; [1]Institute of Radiation Physics, Lausanne University Hospital, Lausanne, SWITZERLAND, [2]Department of Nuclear Medicine, Lausanne University Hospital, Lausanne, SWITZERLAND.

Aim: Similar to PET, absolute quantitative image modality is becoming available in commercial SPECT/CT devices. The goal of this study was to assess the quantitative accuracy of activity concentration recovery as a function of image reconstruction parameters using a NEMA/IEC and an anthropomorphic abdominal phantom. Materials and methods: We performed quantitative ^{99m}Tc-SPECT/CT acquisitions (Siemens Symbia Intevo) of a NEMA/IEC phantom (6 hot spheres, 10:1 sphere to background activity ratio, 1 lung insert) and an anthropomorphic abdominal phantom (commercial Kyoto Liver/Kidney phantom) including a liver insert (volume=1.8L) with 3 hot-spheres (20-30-40mm diameter, 5:1 hot-sphere to liver activity concentration ratio). Background activity concentration (AC_{bg}) was 33/104 kBq/mL in the NEMA/abdominal phantom respectively. SPECT acquisitions used 120 projections (20s/projection). Reconstructions were performed with the proprietary iterative conjugate gradient algorithm. Reconstruction parameters such as iteration number (It range: 4-48, 6 subsets) and gaussian smoothing (FWHM range: 0-10 mm) were varied. Recovery coefficients (RC, mean and max), relative lung error (only for the NEMA phantom) and image noise (COV) on the background were assessed. Results: On the NEMA phantom, measured AC_{bg} was <6% from the expected true value for all tested cases. RC increased less than linearly with iterations. RC relative increment (mean/max) was 13/18%, 8.5/12%, 4/7.5% when varying from It=4 to 8, 12 to 24 and 24 to 48 respectively. It=20 and gaussian smoothing of 7.5mm limited the COV to ≤20%. In these conditions RC (mean/max) were 0.8/1.2 for lesion size > 5 mL and 0.42/0.55 at 1 mL. Lung relative error was fairly sensitive to It changes and ranged from 8 to 12% with increasing smoothing levels. Comparable AC_{bg} accuracy and RC values were found for the abdominal phantom. In this specific case, the higher activity concentration resulted in reduced background variability (COV=10% at It=20, FWHM = 7.5mm). Conclusions: Absolute quantification in commercial SPECT/CT is becoming available. The tested device provided a good accuracy in background activity recovery. Relative lung error was comparable to PET levels assessing the efficient integration of attenuation and scatter corrections with adequate detector modeling. Reliable SPECT quantification has the potential to improve clinical outcome and radiation dosimetry assessments. Reconstruction parameters influence RC (and thus SUV), and optimization is recommended in accordance with clinical requirements.

OP360

Comparison of Image Reconstruction Techniques for Single Photon Emission Computed Tomography (SPECT)

M. Dimcheva, S. Sergieva, A. Jovanovska; Sofia Cancer Center, Sofia, BULGARIA.

The aim of this study was to compare the performance of filtered backprojection (FBP) and iterative reconstruction algorithms available in clinical SPECT software. Materials and Methods: SPECT images of a Jaszczak phantom with cold rod inserts, hot and cold spheres and capillary line sources were acquired on a dual-head SPECT-CT system Symbia T2, Siemens. Image acquisition was performed using a 180° non circular orbit for each detector, with 120 projection angles, 500 000 counts per projections 128 × 128 matrix size, zoom = 1 and pixel size of 4.8mm. A symmetrical 15% wide energy window for the acquisition was centered at 140 keV. The phantom studies were acquired for 30 sec per projection angle. FBP reconstructions were performed by use of the ramp filter limited at the Nyquist frequency (0.5 cycle per pixel). The different type of filter using FBP reconstructions was also considered. The images reconstructed with OSEM were filtered with

a symmetric 3-D Gaussian function having a full width at half maximum of 1 pixel (4.8 mm). Iterative reconstruction of these images was halted after 12 iterations using 4 subsets. Each combination of subsets and iterations was applied to the same set of noisy projection data. The linear attenuation correction was set to μ = 0.15 cm -1. Results: The effect of image smoothing with the use of Gauss filter with different FWHM = mm are shown. Application of Gauss post-filtering degrades the contrast but did not affect the high quality of images. However, this result applies only if Gauss filter's FWHM coefficient does not exceed a double value of the pixel size. Generally, iterative technique (OSEM algorithm) gives better outcomes for both the qualitative and quantitative assessment of SPECT studies in comparison to FBP method. Conclusion: The quality of the image depends on several factors such as spatial resolution, contrast and noise. Proper filter selection is significant for the improvement of the image quality and therefore for the diagnostic evaluation.

OP361

Quantitative Yttrium-90 PET/CT acquisition and reconstruction optimization: An anthropomorphic phantom validation.

S. Gnesin[1], L. Paterne[1], A. Boubaker[2], S. Adib[2], M. Pappon[2], M. Kosinski[1], J. Prior[2], S. Baechler[1], F. Verdun[1]; [1]Institute of Radiation Physics, Lausanne University Hospital, Lausanne, SWITZERLAND, [2]Department of Nuclear Medicine, Lausanne University Hospital, Lausanne, SWITZERLAND.

Aim: Post-radioembolization ^{90}Y spatial distribution and radiation dosimetry can be obtained from clinical quantitative ^{90}Y-PET/CT and used to evaluate treatment outcome and validate predictive dosimetry based on ^{99m}Tc-MAA SPECT/CT. We aimed at determining optimal reconstruction parameters for quantitative ^{90}Y-PET/CT acquisition of an anthropomorphic abdominal phantom. Materials and methods: We performed 10 sequential (1 per day) PET/CT scans (Discovery 690, GE-Healthcare) of an anthropomorphic abdominal phantom including a liver insert (volume=1.8L) with 3 hot-spheres (20-30-40mm diameter). Hot-sphere to liver ^{90}Y activity concentration (AC_{bg}) ratio was 5:1. Initial liver background activity concentration was 1MBq/mL. The rest of the phantom being water filled. AC_{bg} linearity as a function of time was assessed in the liver background. At each time point, recovery coefficients (RC, mean and max) and contrast-to-noise ratio (CNR) in hot spheres and image noise (COV) in the liver background were assessed as a function of different reconstruction parameters: OSEM iterations (It=1, 2, 3, subsets=24), frame duration (F_d=20, 30, 45 min). The impact of Time-of-flight (TOF) information and point-spread-function (PSF) recovery where also assessed. Results: TOF-based reconstructions provided AC_{bg} and RC convergence in 1 and 2 iterations respectively, while 2/3 iterations where required for AC_{bg}/RC to converge to a stable value otherwise. Furthermore, TOF reconstructions minimized spurious signal in regions without activity concentration. Higher RCs were obtained for combined TOF+PSF reconstructions regardless other reconstruction parameter combinations (RC_{mean} from 0.45 in 20-mm spheres; 0.5 in 30-mm spheres; 0.65 in 40mm spheres). Measured AC_{bg} in TOF+PSF reconstructions was <8% from the expected true value down to 300 kBq/ml where no-TOF reconstructions resulted in up to 20% AC_{bg} underestimation. PSF-based reconstructions (It=2, F_d=30 min) displayed COV≥40% for AC_{bg}<300kBq/mL; the same level of noise was found for AC_{bg}<450kBq/mL when no PSF recovery was applied. When using TOF+PSF reconstructions (It=2, F_d=30 min), lesions detectability (CNR>4) was possible down to 1000/800/600 kBq/mL on the 20/30/40mm sphere respectively. Conclusions: Combination of TOF and PSF improves quantitative assessment in intrinsically low-statistic ^{90}Y-PET acquisitions. TOF+PSF based reconstruction significantly reduced correlated noise and improved activity recovery convergence and detectability at matched frame duration.

OP362

FDG uptake quantification: a new approach using tumour delineation on maximum intensity projections

A. de Jong[1], B. A. Blomberg[1], R. A. Nievelstein[1], V. Frings[1], G. Kramer[2], A. J. de Langen[2], O. S. Hoekstra[2], R. Boellaard[2]; [1]UMC Utrecht, Utrecht, NETHERLANDS, [2]VU Medical Center, Amsterdam, NETHERLANDS.

Aim: To study the performance of a new approach for FDG uptake quantification using tumour delineation on PET maximum intensity projections (MIPs). The tool is designed to allow faster tumour delineation by minimizing user interaction (i.e. it is not required to delineate each lesion in all PET image slices). The tool specifically enhances workflow in case the patient has a large number of lesions. Materials and methods: A new tool was developed that generates FDG whole-body PET/CT MIPs at 0 (coronal), 45, 90 (sagittal) and 135 degrees (MIP tool). Next, tumours can be delineated manually with or without intensity thresholds on these MIPs. These MIP delineations are then back-projected to the FDG PET/CT images to obtain an initial tumour mask per lesion. Final tumour delineations are then derived by performing a region growing method starting at the maximum intensity voxel per lesion (within these masks), using a background corrected 50% of maximum threshold (A50%). From the final delineation SUVmax, SUVmean, metabolic active tumor volume (MATV) and total lesion glycolysis (TLG) are derived. The performance of the method was tested using the NEMA NU 2 Image Quality

phantom, and in eight FDG whole-body PET/CT scans of therapy-naïve non-small-cell lung cancer patients. The phantom study was performed according to EARL specifications and the patients were examined following the EANM FDG PET/CT guidelines (Boellaard et al EJNMMI 2015; 42: 328-54). Phantom data will be compared using the expected uptake parameters, and both phantom and clinical data will be compared using an image based A50% method (Cheebsumon et al EJNMMI 2012; 2: 56) to delineate tumours (VOI tool). Results: For the phantom study MIP tool SUVmax approached real SUV by 96%. MIP tool SUVmean approached real SUV by 77%. MIP tool MATV and TLG approached real volume and real TLG by 83% and 65% respectively. For the phantom study SUVmax and SUVmean were identical for both tools. MATV as well as TLG differences were within 1% between both tools. In the clinical studies, SUVmax as well as SUVmean were identical between both tools. MATV and TLG differences ranged between 0-4% and 0-3% respectively. Conclusion: The MIP based delineation approach provided comparable (<4%) results to those obtained using the image based delineation approach. The method may require less user interaction in case of multiple lesions and could be an interesting alternative for assessing total tumour burden quickly.

OP363

The influence of ignoring higher bone attenuation on pelvic and spinal lesions in [18F]NaF PET/MRI examinations.

G. Schramm[1,2], L. Oehme[3], J. Maus[2], F. Hofheinz[2], J. Petr[2], A. Lougovski[2], B. Beuthien-Baumann[3], J. van den Hoff[2]; [1]KU Leuven, Leuven, BELGIUM, [2]Helmholtz-Zentrum Dresden-Rossendorf, Dresden, GERMANY, [3]Universitaetsklinikum Carl Gustav Carus, Dresden, GERMANY.

Aim: MRI-based attenuation correction (MRAC) in clinical whole-body PET/MRI imaging routinely is based on tissue type segmentation. Due to lack of MRI signal in cortical bone and the varying signal of spongeous bone, standard whole-body segmentation-based MRAC neglects the difference between the attenuation coefficient of soft tissue and the (higher) one of bone (MRAC-nobone). In the present work we have quantified the bias caused by MRAC-nobone in spinal and pelvic lesions in 20 PET/MRI examinations with [18F]NaF using the reconstructed PET standard uptake value (SUV) as the relevant measure. Methods: We reconstructed 20 PET/MRI [18F]NaF patient data sets acquired with a Philips Ingenuity TF PET/MRI. First, we used the vendor-provided MRAC-nobone algorithm to reconstruct PET-nobone. Second, we used a threshold-based algorithm developed in our group to automatically segment bone structures in the [18F]NaF PET images. Subsequently, an attenuation coefficient of 0.11 1/cm was assigned to the segmented bone regions in the MRI-based attenuation image (MRAC-bone) which was used to reconstruct PET-bone. The automatic bone segmentation algorithm was validated in 6 PET/CT [18F]NaF examinations. Finally, relative SUVmean and SUVmax differences between PET-bone and PET-nobone of 8 pelvic and 41 spinal lesions, and of other regions such as lung, liver, and bladder were calculated. Results: The comparison of [18F]NaF-based and CT-based bone segmentation in the 6 PET/CT patients showed a Dice similarity of 0.7 with a true positive fraction of 0.72 and a false positive fraction of 0.35. The [18F]NaF-based bone segmentation worked well in the pelvis and spine. However, it showed artifacts in the skull and in the extremities. The analysis of the 20 [18F]NaF PET/MRI examinations revealed relative SUVmax differences between PET-nobone and PET-bone of (-8.7% ± 2.7%, p = 0.01) and (-8.1% ± 1.9%, p = 2.4e-8) in pelvic and spinal lesions, respectively. A maximum SUVmax underestimation of -13.7% was found in lesion in the third cervical spine. The averaged SUVmean differences in volumes of interests in lung, liver and bladder were below 3%. Conclusion: Neglecting higher bone attenuation in MRAC leads to a systematic moderate SUV underestimation in spinal and pelvic lesions. The developed automatic [18F]NaF PET-based bone segmentation allows to include higher bone attenuation in whole-body MRAC and thus improves quantification accuracy for pelvic and spinal lesions in [18F]NaF PET/MRI examinations enabling direct comparisons to PET/CT examinations.

OP364

Evaluation of Siemens SMART Neuro AC Calculated Attenuation Correction for FET PET

P. Ritt, T. Kuwert, C. von Gall; Clinic of Nuclear Medicine, University Hospital, Erlangen, GERMANY.

Aim: Correction for photon attenuation (AC) in PET is essential for quantitative imaging. Before hybrid PET/CT scanners were available, emission-based, calculated AC was common. It is generally accepted that for PET examinations of the brain, hybrid PET/CT often adds little benefit beyond AC. For this reason, enhanced calculated AC methods have been (re-)introduced into hybrid PET/CT and PET/MRI scanners. We aimed for evaluating the accuracy of one of these calculated AC methods, namely Siemens' SMART Neuro AC, which has recently become available. Materials and MethodsFET PET/CTs were acquired for 17 patients (6 male, 11 female, mean age 36±15 y), suspected of recurrent cerebral malignancies. The average injected dose was 200±50 MBq at 73±18 kg. The PET images were reconstructed from the counts acquired between 30 and 60 min p.i. The reconstruction was carried out with OSEM3D at 12 subsets, 4 iteration, and 5.0 mm Gaussian smoothing. AC images were obtained using the CT data (CTAC), as well as by applying the SMART Neuro calculated attenuation correction (calcAC).

Images that represent the difference between both AC strategies were generated and non-rigidly registered to an MRI atlas. By this, the differences between calcAC and CTAC were evaluated in 19 MRI-defined brain regions. Additionally, the differences for FET-positive lesions were assessed in terms of change of the ratio of the lesion's SUVmax to the SUVmean of a non-affected, contralateral region. Results: CalcAC leads, on average, to an underestimation of activity concentration when compared to CTAC. Subsequently, the activity of calcAC images in the parietal, occipital, frontal, temporal lobes, and in the cerebellum were 90.0: 84.4: 94.6: 89.5: 87.9% of the CTAC images' values respectively. However, the differences were symmetrical in left-right direction. Consequently, the deviations for the quotient SUVmax/SUVmean were smaller, on average 2.8 percent and ranging from 0.1 to 9.9%. This deviation did not lead to any reclassification of the lesions as either benign or malignant when a threshold of x was used for this purpose. Conclusion: Although finding slightly higher deviations between CTAC and calcAC reconstructed images than reported by the manufacturer (99% of brain pixels below 10% error), the bias will most likely not influence diagnoses based on SUV ratios. This fact may be attributed to the left-right symmetry of the bias. Nevertheless, one has to keep in mind the potentially lower measured activity and should be especially cautious when comparing to data obtained with CTAC in prior examinations.

Interim [18F]-FDG-PET in MALT lymphoma patients treated with immunotherapy: which Deauville score is the best predictor of end-of-treatment outcome?

T. Traub-Weidinger, M. Raderer, B. Kiesewetter, M. Weber, G. Karanikas, M. Mitterhauser, M. Hacker, M. E. Mayerhoefer; Medical University of Vienna, Vienna, AUSTRIA.

Aim: To determine, which score of the 5-point Deauville treatment response scale, as assessed by interim [18F]-FDG-PET, is the best predictor of end-of-treatment outcome in patients with FDG-avid MALT lymphoma undergoing immunotherapy. Method: Our prospective study included patients with histologically verified MALT lymphoma scheduled to receive rituximab-based immunotherapy and to undergo whole-body [18F]-FDG-PET/CT before treatment, after three therapy cycles (interim), and after six therapy cycles (end-of-treatment). Patients without FDG avidity at pre-treatment [18F]-FDG-PET were excluded. In the remaining patients, treatment response of all nodal and extranodal lymphoma lesions visible on pre-treatment [18F]-FDG-PET was assessed on interim [18F]-FDG-PET, separately for four different cut-off scores of the Deauville scale: score 2 = uptake higher than the background activity, score 3 = uptake higher than the mediastinal blood pool, but lower than the liver; score 4 = uptake comparable to, or slightly higher than the liver, score 5 = uptake clearly higher than the liver. For each of the four lesion-based cut-off scores, the ICML/Lugano classification was used for assigning each patient to an outcome class: complete remission (CR), partial remission (PR), stable disease (SD), or progressive disease (PD). These interim outcomes were then compared to the end-of-treatment outcomes according to the ICML/Lugano classification using kappa coefficients. Results: Fifteen patients with 35 lesions met our participation criteria. Using a Deauville cut-off score of 2, five patients were rated as CR, six patients as PR and four as SD at interim restaging. Using a Deauville cut-off score of 3, seven patients were rated as CR, four patients as PR and four as SD at interim restaging. Using a Deauville cut-off score of 4, eight patients were rated as CR, three patients as PR and four as SD at interim restaging. Using a Deauville cut-off score of 5, ten patients were rated as CR, two patients as PR, and three as SD at interim restaging. The Deauville scores 2, 3, 4, and 5 showed agreement with end-of-treatment outcomes (nine CR, three PR, three SD, and no PD) in 66.7%, 80%, 86.7%, and 86.7%, with kappa values of 0.5, 0.67, 0.77, and 0.75, respectively. Conclusion: Interim [18F]-FDG-PET after three cycles of immunotherapy can predict the end-of-treatment outcome in patients with FDG avid MALT lymphoma using a Deauville cut-off score of 4.

OP366

The Deauville Criteria and Metabolic Parameters as Prognostic Factors in Interim PET in Hodgkin Lymphoma: a Single Centre Experience

M. Cuzzocrea[1], L. Guerra[2], F. Elisei[2], C. Crivellaro[1,2,3], E. De Ponti[4], S. Bolis[5], L. Baratto[1], S. Pacella[1], M. Arosio[2], C. Landoni[1]; [1]Department of Nuclear Medicine, University of Milan-Bicocca, Milan, ITALY, [2]Department of Nuclear Medicine, San Gerardo Hospital, Monza, ITALY, [3]Tecnomed Foundation, University of Milan-Bicocca, Milan, ITALY, [4]Department of Medical Physics, San Gerardo Hospital, Monza, ITALY, [5]Department of Haematology, San Gerardo Hospital, Monza, ITALY.

BACKGROUND AND AIM OF THE STUDY: 18-Fluorodeoxyglucose (FDG) positron emission tomography/computed tomography (PET/CT) is the most accurate tool for staging, treatment monitoring, and response evaluation in Hodgkin lymphoma (HL). The interim-PET (i-PET) is considered predictive of final response and prognosis; early determination of treatment sensitivity by i-PET is the best tool to guide

individualized, response-adapted treatment. This study aimed to explore the prognostic role of i-PET in patients with HL: Deauville criteria, SUVmax and SUVpeak were respectively correlated to disease free survival (DFS) and overall survival (OS). METHODS: We retrospectively evaluated 83 patients (47 men, 36 women; mean age 40±14 years, range 20-73) with newly diagnosed HL, stage I-IV disease (5 stage I, 39 stage II, 18 stage III and 21 stage IV). All patients were studied with 18F-FDG PET/CT prior to treatment (baseline PET), after two cycles of chemotherapy (i-PET) and at the end of the treatment. Treatment was not changed according to the results of the i-PET. i-PET were qualitatively interpreted by two observers using the Deauville five-point scale. A score of 1-3 was regarded as "negative" and 4 or 5 as "positive". Lesions with the highest FDG uptake on i-PET was selected as "reference lesion" and SUVmax and SUVpeak were calculated. All datasets were correlated with DFS and OS. ROC curves were analysed to find best SUVmax and SUVpeak thresholds predictive for complete response and OS. Kaplan-Meier method was used to evaluate DFS and OS. RESULTS: The median follow-up was 36 months for DFS and 50 months for OS. i-PET scan resulted negative for 66 patients (79.5%) and positive for 17 patients (20.5%). The positive and negative predictive values of i-PET for predicting treatment outcome were 47,0% and 93,9%, respectively. The DFS and OS for positive i-PET and negative i-PET were 58.2% and 96.7% ($p<0.0001$), and 70.6% and 98.5% (p 3 were relevant on OS ($p=0.014$ and $p=0.022$, respectively); no significant differences were found in DFS. CONCLUSIONS: Early interim PET/CT is a good predictor of outcome in patients with HL. Deauville criteria using a cut off between 3 and 4 was reliable to discriminate patients with poor from good prognosis. Similarly, metabolic features of reference lesion (SUVmax ≤ 3 and SUVpeak < 3) are predictors of good prognosis.

OP367

PET/FDG and Interleukin-10 as prognostic indicators in Diffuse Large Type B-Cell Lymphoma

L. Tagliabue[1], L. Ottobrini[2], C. B. Colombo[2], S. Seghezzi[3], I. Libani[2], A. Moro[1], M. Violati[1], L. De Fazio[4], A. Bertolini[5], P. Foa[2], G. Lucignani[2]; [1]AO San Paolo, Milano, ITALY, [2]University of Milan, Milano, ITALY, [3]AO Treviglio-Caravaggio, Treviglio, ITALY, [4]AO Lodi, Lodi, ITALY, [5]AO Valtellina e Chiavenna, Sondrio, ITALY.

AIM: Diffuse large B-cell lymphoma (DLBCL) is the most common non-Hodgkin's lymphoma. In these patients, FDG/PET has been reported to be a good prognostic indicator when performed during therapy (interim-PET/FDG) and more so at the end-of-therapy. However, because of the still limited prognostic accuracy of interim-PET/FDG and, to some extent, also of end-of-therapy-FDG/PET, given the evidence of IL-10 involvement in DLBCL genesis and progression, we aimed to evaluate the prognostic role of combined IL-10 serum assay and PET/FDG. Patiens and methods: Twenty-four drug-naive patients with DLBCL Ann Arbor stage > I underwent both IL-10 serum assay and PET/FDG evaluation three times: at the time of diagnosis, after 2 cycles of R-CHOP (interim), and again at the end-of-therapy. PERCIST criteria were used for the assessment of PET/FDG studies. Results: Interim-PET/FDG allowed us to discriminate two patient populations: one with a complete metabolic response, i.e. PET/FDG-negative (15/24 patients), and another with either partial metabolic response or progressive disease, i.e. PET/FDG-positive (9/24 patients). At end-of-therapy, PET/FDG scan was negative in 19/24 and positive in 5/24 patients, as PET/FDG became negative in 4 patients that were PET/FDG-positive at interim. A disease relapse was observed within 36 months after therapy completion in 2/19 patients and in 4/5 patients that were FDG/PET-negative and FDG/PET-positive, respectively, at the end-of-therapy. IL-10 serum levels, detectable in serum at staging but not after therapy, did not appear to be significantly related to metabolic response. The results of IL-10 assay and PET/FDG analyzed together conveyed these novel findings: A) High IL-10 levels (> than 10pg/ml) at staging were recorded among all the relapsing patients (i.e. 4/5 PET/FDG-positive and 2/19 PET/FDG-negative at the end-of-therapy). B) When values of IL-10 measured at staging are combined with either interim- or EOT-PET/FDG results, it is possible to stratify patients with high/low probability of relapse with the same accuracy. C) Low levels of IL-10 appear to characterize a population of "slow responders with favorable prognosis", i.e. patients PET/FDG-positive at interim and PET/FDG-negative at end-of-therapy, that do not relapse. Conclusions: In DLBCL patients, following 2 cycles of R-CHOP, the combination of IL-10 assays and PET/FDG increases the prognostic accuracy by decreasing both false negative and false positive prognoses, and, at the end-of-therapy, allows to identify patients at high risk for relapsing disease among both PET/FDG-positive and PET/FDG-negative subjects. IL-10 could be routinely used along with FDG/PET for the prognostic assessment of DLBCL patients.

OP368

Assessing Bone Marrow Involvement in DLBCL: Comparison of FDG PET and Bone Marrow Biopsy

V. Ptacnik, K. Benesova, E. Cmunt, J. Kubinyi, M. Trneny; Charles University Prague, Prague, CZECH REPUBLIC.

Aim: FDG PET/CT is important imaging method for clinical stage determination of DLBCL. According to new guidelines (Cheson et. al., J Clin Oncol 2014) FDG PET can in majority of cases substitute bone marrow biopsy for possible bone marrow involvement evaluation. Methods: Retrospective analyze

of 217 consecutive patients was done. The group consists of 112 men and 105 women (median age 65 years) with newly diagnosed DLBCL. All had available staging bone marrow biopsy (BMB) and FDG PET. We compared results of PET and BMB to establish the differences between positivity rates of each method. Evaluation of PET was done visually, increased FDG uptake was considered positive. Focal and diffuse FDG hyperaccumulation was distinguished. BMB was evaluated histologically to determine type of involvement and percentage of malignant cells. The confrontation of findings was done; impact to clinical stage (CS) and outcome of treatment were compared. Results: Comparing PET and BMB findings, 82% were congruent, 71.9% of them were negative and 10.1% positive; 17.9% findings were contradictory: 13.4% were PET only positive and 4.6% BMB only positive. Out of 10 BMB only positive patients 8 had discordant histological finding and 2 had concordant finding with low level of bone marrow infiltration. Analyzing PET only, 23.5% patients were positive, BMB positive were 14.7% findings and positive finding according to at least one method had 28.1% patients. Seven patients had diffusely increased FDG uptake in bone marrow, 4 of them had positive BMB finding, 3 had negative bone marrow biopsy - these were considered as false positive. PET driven clinical stage was downgraded from stage IV to localized by BMB in 2 cases and upgraded from localized to stage IV in 1 patient. 30 of 32 patients with initial bone marrow involvement had BMB after treatment, 2 (6.7%) remained BMB+. 46 of 51 initially PET positive patients had restaging PET after therapy, 4 (8.7%) remained positive. Two of 22 initially PET+/BMB+ patients lingered PET+/BMB+ after therapy, none remained positive only with one method. Conclusions: PET compared with BMB increases finding of bone marrow involvement from 14.7% to 23.5%, combining the methods we get on 26.7% positive findings. PET misses BM involvement in 4.6% of patients. Almost half of the diffuse PET+ cases are false positive, therefore we recommend bone marrow biopsy performance in these cases.

OP369

Prolonged overall survival in metastatic melanoma with low tumor burden at anti-PD1 initiation: CT-scan, 18-FDG-PET and blood samples

L. Dercle, S. Ammari, M. Texier, E. Lanoy, S. Champiat, D. Deandreis, M. Terroir, A. Marabelle, M. Schlumberger; Gustave Roussy, Villejuif, FRANCE.

PURPOSE: Immunotherapies targeting the pathway of the programmed death-1 ("anti-PD1") receptor lead to a delayed clinical response that is sustained in only a fraction of patients with metastatic melanoma. The rationalization of the use of this costly drug requires identifying patients with demonstrated clinical benefit. Patients with serum LDH>250 (biologic tumor burden [TB], blood sample) are considered at high risk by the AJCC M-staging system. Our group demonstrate that a TB_{3D}>202cm3 (anatomic TB, CT-scan) is classified high risk. The primary objective was to characterize if biomarkers extracted from the whole metastatic tumor volume by ^{18}F-FDG PET at anti-PD1 initiation predict overall survival [OS]. METHODS: Patients with metastatic melanoma prospectively included in phase I trials were eligible. All the lesions measurable at baseline within the whole tumor volume were measured on CT-scan (anatomic TB: TB_{1D}, TB_{2D}, TB_{3D}), on FDG-PET (metabolic TB: MTV; glycolysis: TLG, SUV_{max}, SUV_{mean} and HISUV). The respective effect on OS and PFS was evaluated and derived from Cox proportional hazard models. RESULTS: Data were available in 28 patients with a median follow-up of 13.2 months. A significant correlation of biomarkers of TB (p<.05) was demonstrated for anatomic TB (TB_{3D} vs TB_{1D}: r=.78), metabolic TB (MTV vs TLG: r=.93), MTV/TLG vs TB_{3D} (r=.61/.62) and MTV/TLG vs LDH (r=.37/.40). Patients with lower TB showed a prolonged survival: TB_{1D} <113 (p.0008), LDH<250 (p.01), MTV<21 cm3 (p.02) and TLG<171 (p.13). Hazard ratio of death for one SD increase were: 2.07 [1.31; 3.27] for LDH (p<.01), 2.64 [1.57; 4.45] (p<.01) for TB_{1D}, 2.09 [1.33;3.30] (p<.01) for TB_{2D}, 2.32 [1.45; 3.72] (p<.01) for TB_{3D}, 1.41 [0.87;2.26] (p=.16) for MTV, 1.08 [0.67;1.75] (p=0.76) for TLG, .87 [.47;1.59] (p=.21) for SUVmax, 1.10 [.37;3.32] (p=.86) for SUVmean and 0.81 [.45;1.43] (p=0.46) for HISUV. CONCLUSION: Proof of concept that a screening of good candidate for immunotherapy is achievable by medical imaging: low TB (anatomic, metabolic and biologic) at the initiation of anti-PD1 show prolonged survival. An increased TB on CT-scan (TB3D>202cm3, TB2D>113mm), and/or 18F-FDG-PET (MTV) and/or blood samples (LDH>250) might identify high risk patients and the most accurate imaging modality might depend on the dominant site of the metastases (e.g.: FDG-PET for bone, CT-scan for liver). Biomarkers estimating the intensity of the glycolytic activity within the tumor volume (SUVmax, SUVmean, HISUV) are not prognostic of OS.

OP370

Cost-effectiveness analysis of sentinel node biopsy in patients with primary cutaneous melanoma

P. Serra-Arbeloa[1,2], Á. O. Rabines-Juárez[1], S. Álvarez-Ruiz[3], F. Guillén-Grima[2]; [1]Complejo Hospitalario de Navarra, Pamplona, SPAIN, [2]Universidad Pública de Navarra, Pamplona, SPAIN, [3]Hospital Universitario Miguel Servet, Zaragoza, SPAIN.

Aim: To develop a cost-effectiveness analysis of the role of the sentinel node biopsy (SNB) in patients with different Breslow thickness primary cutaneous melanomas (CM) over a 10 year time horizon, using the health care system perspective. Methods: A decision tree model was used to compare two different

strategies of management of patients diagnosed with CM, wide excision with SNB followed by complete lymph node dissection (SNB) and wide excision only (WE). The economic and clinical outcomes, measured as mean total cost per patient, cost effectiveness ratio (CER), incremental cost effectiveness ratio (ICER), life years saved (LYSs) and quality-adjusted life years (QALYs), were calculated from the model. Transition probabilities of disease progression and survival rates were obtained from the published literature after a systematic review, and the costs from government official publications. A sensitivity analysis was performed to test the robustness of the model, analysing the changes in different variables of every branch of the tree. Results: Base case analyses suggested that the mean total cost per patient with intermediate thickness CM receiving the SNB strategy was 25,822 € with 0.84 LYSs, 0.69 QALYs, and a CER of 30,812 €/LYS and 37,125 €/QALY; being of 22,683 € with 0.81 LYSs, 0.67 QALYs, 28,143 €/LYS and 33,780 €/QALY when the patient received the WE only. The ICER for SNB was 97,849 €/LYS and 130,508 €/QALY. In a patient with thick CM the mean total cost of the SNB was 36,101 € with 0.63 LYSs and 0.46 QALYs, and a CER of 57,263 €/LYS and 77,896 €/QALY. For a WE patient was 18,185 € with 0.67 LYSs, 0.49 QALYs, 27,264 €/LYS and 37,162 €/QALY. The ICER for SNB was -490,202 €/LYS and -692,074 €/QALY (Northwest quadrant; SNB dominated by WE). The mean cost of the patient with thin CM was 25,980 € with 0.92 LYSs, 0.72 QALYs, 28,897 €/LYS and 35,943 €/QALY for the first strategy, and 7,800 € with 0.92 LYSs, 0.83 QALYs, 8,877 €/LYS and 9,365 €/QALY for the second one. The ICER was -9,217,203 €/LYS and -165,191 €/QALY (Northwest quadrant). The sensitivity analysis showed no significant differences in the results. Conclusion: SNB appears not to offer an improvement in health outcomes in terms of LYSs and QALYs for patients with thick and thin CM, and a slight benefit for those with intermediate CM. SNB seems not to be cost-effective compared with WE in any CM thickness.

OP371

The role of preoperative lymph node ultrasound in patients with primary cutaneous melanoma: a meta-analysis

P. Serra-Arbeloa[1,2], Á. O. Rabines-Juárez[1], S. Álvarez-Ruiz[3], F. Guillén-Grima[2]; [1]Complejo Hospitalario de Navarra, Pamplona, SPAIN, [2]Universidad Pública de Navarra, Pamplona, SPAIN, [3]Hospital Universitario Miguel Servet, Zaragoza, SPAIN.

Aim: The objective of the study was to evaluate the diagnostic accuracy of high-resolution ultrasound (US) in detecting nodal involvement before performing the sentinel node biopsy (SNB) in patients with primary cutaneous melanoma (CM). Methods: A systematic review was conducted following the Preferred Reporting Items for Systematic reviews and Meta-Analyses (PRISMA) guidelines criteria. An electronic search using the terms “melanoma” and “sentinel node” was performed in MEDLINE, Scopus and Web of Knowledge (WoK) databases. Studies were considered if they reported data on preoperative lymph node US accuracy that allowed creating a 2x2 table, excluding those with high risk of bias (QUADAS-2 criteria). A meta-analysis was used to calculate the pooled sensitivity and specificity with their 95% confidence intervals (95%CI) and to test heterogeneity. Sensitivity and subgroup analyses were performed to search the articles that provided more heterogeneity. After the study, a level of recommendation for the use of the technique, according to the Scottish Intercollegiate Guidelines Network (SIGN) criteria, was established. Results: Seven articles were included. Two of them reported accuracy data per patient, 2 per node and 3 per patient and node. A total of 1,229 patients and 2,270 nodes were considered, with a mean SN positivity rate of 11.9% and a mean of false negative rate of 16,4%. In the results per patient, the weighted sensitivity was 33% (95%CI=24-36%) and the weighted specificity 93% (95%CI=91-94%). When the results were obtained per node, the weighted sensitivity and specificity were respectively 16% (95%CI=13-20%) and 97% (95%CI=96-97%). In both cases, a high heterogeneity between the studies was found. After sensitivity and subgroup analysis, the heterogeneity persisted and when the articles that provided more heterogeneity were excluded, the sensitivity of the preoperative US per patient decreased up to 25%. Conclusions: Preoperative ultrasonography to detect lymph node involvement in patients with CM presents a very low sensitivity; a negative ultrasonographic result does not exclude lymph node metastases. US cannot replace SNB in the detection of lymph node metastases. The maximum level of recommendation of US for this indication is C (being A the highest and D the lowest).

OP372

Lymphoscintigraphy and Sentinel Lymph Node Biopsy in Cutaneous Melanoma: Analysis of 201 Patients From a Single Institution

L. Jaukovic, M. .Rajović, M. Radulovic, L. Kandolf-Sekulovic; Military Medical Academy, Belgrade, SERBIA.

AIM: Sentinel lymph node biopsy (SLNB) is widely accepted method in the management of clinically localized cutaneous melanoma. The aim of this study was to report the results on patients scheduled for preoperative lymphoscintigraphy and SLNB. METHODS: At Medical Military Academy, Belgrade, 250 patients were identified for SLNB between 2010-2014. Out of them, retrospective review of 201 patients with cutaneous melanoma was performed. Lymphoscintigraphy was used

in all the patients and dual labeling method (blue dye/ nanocolloid) in less than one half of them. To delineate the relation of patients', tumors' and scintigraphic characteristics with positive SLN status, we examined all variables by univariate logistic regression with odds ratios representing effect size. RESULTS: Overall identification rate of SLN was 98.5%. Positive SLN (metastatic, one or more) was seen in 47 (23.4 %) patients. Drainage to one regional basin was seen in 176 (87.6 %) and multiple drainage regions (up to three) - in 24 patients (11.9%). In transit lymph nodes were detected in 20 patients. Univariate regression analysis with 201 cases included in model revealed Breslow thickness, nodular melanoma histological subtype and acral localization- to be significant independent predictors of SLN status ($p<0.05$). CONCLUSION: Beside the well established primary tumor thickness as the predictor of SLN positivity, we observed acral body site location and nodular melanoma to significantly enhance the risk for regional metastases. Our data confirm that multidisciplinary approach of SLNB is relevant as a diagnostic and staging procedure in cutaneous melanoma patients.

Y-90 imaging for dosimetry in radioembolization: comparison between scatter corrected bremsstrahlung SPECT/CT and time-of-flight PET/CT

Y. K. Dewaraja[1], P. M. Novelli[1], J. A. Fessler[1], M. U. Feng[1], R. Nelson[1], J. Rothley[1], M. Ljungberg[2], P. L. Roberson[1], S. J. Wilderman[1]; [1]University of Michigan, Ann Arbor, MI, UNITED STATES, [2]Lund University, Lund, SWEDEN.

Aim: To compare quantitative imaging of Y-90 by scatter-corrected bremsstrahlung SPECT (SPECT+SC) and PET with time-of-flight (PET+TOF) for dosimetry applications. Methods: A torso phantom with 0.74 GBq of Y-90 in liver and 60 mL tumor (5:1 tumor-to-liver) was imaged with a Siemens Symbia SPECT/CT and Biograph mCT PET/CT using a prolonged acquisition (90 min in both) such that the total counts were similar to a 20 min patient scan with 4 times the activity, which is typical for imaging following radioembolization with glass microspheres. A high-energy collimator and 105-165 keV window was used for SPECT. The in-house 3-D OSEM SPECT reconstruction used an analytical projector coupled with object-specific scatter estimates from Monte Carlo (MC) updated after 10 iterations. 3-D OSEM PET reconstruction was performed with 1 - 5

iterations (21 subsets) with resolution recovery and TOF. The tumor and healthy liver activity was quantified using a self-calibration based on the known liver activity. For PET, activity was also quantified directly using the image Bq/mL values provided by the system. Post-radioembolization SPECT/CT and PET/CT for 2 patients were also reconstructed as above and quantified using a calibration from the phantom experiment. 3-D dosimetry was performed using a previously developed MC algorithm. Results: Tumor contrast, background noise, tumor quantification error and healthy liver quantification errors were 56%, 14%, 30%, -8% respectively for SPECT without scatter correction, but improved to 94%, 12%, 4, -1% respectively for SPECT+SC after just 3 updates of the scatter estimate. The corresponding results for PET+TOF (1 iteration, 21 subsets) were 100%, 24%, -0.5%, 0.1%, without substantial improvement with more iterations. At equivalent noise, SPECT+SC had better contrast and quantification than PET+TOF. Using the direct PET quantification, activities were underestimated by up to 19%. In patients, the estimated liver activity compared to 'truth' (total administered activity accounting for lung shunt) was within 14% for SPECT without SC, 6% for SPECT+SC and 9% for PET+TOF. Using the direct PET quantification, patient liver activity was underestimated by up to 27%. There was good agreement between SPECT and PET based tumor and liver dose volume histograms only when SC was included (mean doses agreed to within 12%). Conclusions: For relatively large targets, quantitative accuracy and contrast of bremsstrahlung SPECT+SC approaches that of PET+TOF, but with less noise. Similarly in patients, dose estimates based on SPECT+SC agreed well with estimates based on PET+TOF. Further studies with small targets are needed to compare resolution.

OP381

Study of the impact of PSF and Noise on Dose Volume Histograms (DVH) for the dosimetry of Y-90

H. Levillain, **M. Sanchez-Garcia**, A. Dieudonné; Department of Nuclear Medicine, Beaujon Hospital, Assistance Publique-Hôpitaux de Paris (APHP) & INSERM U1149, Clichy, FRANCE.

Our aim was to evaluate the degradation of dose-volume histograms (DVH) induced by partial volume effect (PVE) and noise independently and for simulated SPECT and PET. Methods: First, we have analytically modelled uniform spheres (contrast=10) with different diameters: 1 cm, 5 cm and 10 cm (S1, S2, S3 respectively). We have analytically simulated the effects of PVE and noise. PVE was simulated with the convolution of a Gaussian point spread function (PSF) characterised by full width at half maximum (FWHM). The noise was simulated by a log-normal distribution characterised by relative standard-deviation (RSD). For the 3 spheres, PVE and noise were applied separately for distinct analysis, with 2 PVE: FWHM=5mm and 10mm, and 2 noises levels: RSD=0.10 and 0.3, representative of the clinical routine. Then we have simulated the degradation of SPECT and PET devices, according to what is observed in clinical routine, with respectively (FWHM=10 mm, RSD=0.10) and (FWHM=5 mm, RSD=0.3). The DVHs were computed from absorbed dose calculation using dose-point kernels (DPK) in each generated activity map, including the non-degraded one, with a homogenous water medium. Finally, DVHs were compared to theoretical ones, for the following absorbed dose criteria: D80, D50, Dmean and D20. Results: PVE decreased D80, D50 and had no impact on the other absorbed dose criteria, except for S1 for which D20 was underestimated of 66%. The more PSF was close to sphere's size, the more the effect of PVE was important. As an example, for all spheres, D80 (for which one PVE had a major impact) was underestimated between 38% and 8.1% and between 61% and 20% for FWHM of 5mm and 10mm respectively. Noise decreased D80 and increased D20 and had no influences on D50 and Dmean. For the most degrading noise level RSD=0.1, D80 was underestimated between 0.4% and 9.5%, D20 was overestimated for all spheres, between 6.4% and 12.2%. The simulated SPECT underestimated D80 up to 80%, D50 up to 82%, Dmean up to 79%, and D20 up to 78%. The simulated PET underestimated D80 up to 21%, D50 up to 17%, Dmean up to 12%, and D20 up to 4%. Conclusion: This study highlights the impact of PVE and noise on the DVHs, showing the importance of controlling and evaluating these effects to set-up absorbed dose protocols.

OP382

An inter-operator study of the accuracy of Y-90/In-111 DOTATATE dosimetry using an anthropomorphic phantom

T. Sanderson, **J. Gear**, A. Divoli, A. Craig, M. Gray, I. Murray, G. Flux; The Royal Marsden NHSFT, Sutton, UNITED KINGDOM.

Aim: To determine the accuracy and inter-operator variability of dosimetry performed on patients undergoing Y-90/In-111 DOTATATE radiopeptide therapy using a 3D printed anthropomorphic phantom. Method: The 3D printed phantom was based on a cohort of neuroendocrine patients and contained liver, spleen, kidney and spherical hepatic lesions. Organs and lesions were filled with a representative concentration of Y-90 and In-111

to that observed clinically. SPECT/CT imaging was performed using the clinical dosimetry imaging protocol and processed by 4 independent operators. Post therapy SPECT imaging was performed on a Siemens Symbia Intevo SPECT/CT system at 24, 48 and 72 hours post administration with 15% energy windows over the 171 and 245 keV In-111 peaks and 6% windows either side of the peaks to enable triple energy window scatter correction. Siemens Flash 3D reconstruction was performed using a CT attenuation correction. 6 subsets and 8 iterations were sufficient for reasonable image quality without over amplifying image noise or generating excess resolution recovery artefacts. Scatter data was smoothed using a 12 mm Gaussian kernel and corrected during reconstruction. Organ and lesion segmentation was carried out using the CT image. VOI counts were converted to activity using a pre-acquired calibration dataset. Time-activity curves were plotted and cumulated activity was determined from the integral of a single exponential fit. Y-90 organ S-factors for the standard reference man were scaled for organ mass and lesion S-factors were interpolated from unit-density sphere S-factors from Olinda. In addition a digitally segmented image of the phantom was inputted into the OEDIPE Monte Carlo dosimetry tool to provide organ specific S-factors. Results: Absorbed doses measured by different operators was consistent for all VOIs with a coefficient of variation below 20%. Mean percentage errors in activity quantification across all VOIs ranged from 4% to 21% with an average deviation of 10%. Absorbed dose accuracy ranged from 4% for lesions and organs greater than 4 cm in diameter to 22% for lesions 2 cm in diameter. The Percentage differences when using mass scaled S-factors to that calculated using Monte Carlo varied from 3 to 10%. Inaccuracies due to not considering organ cross-dose were less than 1%. Conclusions: The accuracy and reproducibility of dosimetry calculations should be determined to enable dose-response relationships to be investigated. The results from this study compare favourably with absorbed dose calculation accuracies suggested in the literature of 30-100% and are sufficient to validate the dosimetry methodology employed.

OP383

Modelling of a Patient-Specific ^{177}Lu-Dotatate Therapy Renal Dosimetry Process for Investigation of Uncertainties

J. Gustafsson[1], G. Brolin[1], M. Cox[2], M. Ljungberg[1], L. Johansson[2], K. Sjögreen Gleisner[1]; [1]Department of Medical Radiation Physics, Clinical Sciences Lund, Lund University, Lund, SWEDEN, [2]National Physical Laboratory, Teddington, UNITED KINGDOM.

AIM: The aim was to investigate the uncertainties in kidney absorbed dose and biologically effective dose (BED) for SPECT/CT-based patient-specific dosimetry in ^{177}Lu-Dotatate therapy. MATERIAL AND METHODS: A Monte Carlo method for uncertainty propagation was applied to a computer model of the dosimetry process. As basic tools, simulated SPECT images of three anthropomorphic computer phantoms coupled to pharmacokinetic models of ^{177}Lu-Dotatate were used. The phantoms had well-defined absorbed-dose rate curves for every structure and hence reference values, corresponding to "true values", of renal absorbed doses and BED. From the reconstructed SPECT images (60 projections, 45 s/projection, OSEM with compensation for attenuation, scatter and distance-dependent resolution) the renal absorbed-dose rate was determined at four time-points (0.5 h, 24 h, 96 h and 168 h) post injection. Curve fitting yielded estimates of the absorbed dose and BED (α/β = 2.6 Gy, T_{rep} = 2.8 h). Uncertainties were introduced in different steps of the process, in particular in the *a*) estimation of system sensitivity, *b*) variability in imaging time-points, *c*) SPECT projection noise, *d*) CT-derived density map used for attenuation and scatter correction and for absorbed-dose rate determination, *e*) ^{177}Lu emission spectrum, *f*) kidney VOI delineation, and *g*) recovery coefficient. The kidney absorbed dose and BED were then quantified in 256 Monte Carlo realisations from which the mean and standard deviation (SD) were derived. By sequential replacement of the individual variable parameters by fixed values, the decrease in dispersion was analysed as a measure of the parameter's influence on the combined uncertainty in absorbed dose. RESULTS: The kidney absorbed dose SDs were approximately 6 % for all phantom kidneys, with the variability in kidney recovery coefficient and the camera sensitivity being the most influential contributors. The derived deviations between mean and reference absorbed dose were between -0.4 % and 6.7 %. The BED results were similar to the absorbed dose results. CONCLUSIONS: Using the dosimetry process model with assumed but plausible standard uncertainties in input parameters, the standard uncertainty in kidney absorbed dose was approximately 6 %. The most important contributors were effects which are correlated between imaging time-points, e.g. the recovery coefficient and the system sensitivity, while uncorrelated effects, like SPECT projection noise and kidney VOI delineation variability, had marginal influence on the absorbed dose estimations. The BED was not appreciably affected by variations in the absorbed-dose rate curve beyond the associated uncertainty in absorbed dose.

OP384

Dosimetry of Lu-177 DKFZ-PSMA-617 for the treatment of metastatic prostate cancer using quantitative SPECT/CT

A. Delker, W. Fendler, A. Brunegraf, A. Gosewisch, F. Gildehaus, P. Bartenstein, G. Böning; University of Munich, München, GERMANY.

Aim: Estimation of radiation dose helps to determine the optimal activity to achieve best therapeutic effect in combination with limited side effects. Our aim was to perform first image based dose calculations for tumor tissue and critical organs after application of Lu-177 DKFZ-PSMA-617 for the treatment of metastatic prostate cancer. Methods: Whole-body planar images and SPECT/CT of the abdomen data were acquired in 10 patients (mean age 70 years) at approximately 1h, 24h, 48h and 72h after administration of 3.7 GBq Lu-177 DKFZ-PSMA-617 on a Siemens Symbia SPECT/CT. Quantitative 3D SPECT OSEM reconstruction was performed with corrections for photon scatter, photon attenuation and detector blurring. A camera specific calibration factor derived from phantom measurements was applied. Total activity in the kidneys, liver, spleen, salivary glands and 4 tumor lesions in each patient were calculated using a combination of linear approximation, exponential fit, and target-specific S values according the MIRD concept. Results: The average estimated dose ± SD was 2.4 Gy ± 0.6 Gy in the kidneys, (0.7 Gy/GBq), 0.4 Gy ± 0.2 Gy in the liver, 0.4 Gy ± 0.1 Gy in the spleen and 5.1 Gy ± 2.0 Gy in the salivary glands (1.4 Gy/GBq). Critical dose limit for the kidneys was not reached in any of the patients. Doses for tumor lesions up to 35.7 Gy were observed. An increased uptake in the intestine was observed after approx. 24h with overlap to the kidneys by about 50-75% for planar images. Conclusions: Critical organs are the salivary glands and the kidneys. Kidneys, based on their vital function, are the dose limiting organ in analogy to other Lu-177 based therapies. Quantitative 3D SPECT improves accuracy of kidney dose estimation due to reduced overlap by activity on the colon on late images. Our results further suggest that the activity administered for each cycle could be increased to optimally exploit the tumor dose.

OP385

Accuracy of Triple Energy Window vs. Analytical Photon Distribution Scatter Corrections in Lu-177 Studies

C. F. Uribe[1,2], L. Frauenstein[3,1], P. L. Esquinas[1,2], J. Tanguay[1], M. Gonzalez[4], A. Celler[1]; [1]Medical Imaging Research Group, University of British Columbia, Vancouver, BC, CANADA, [2]Department of Physics and Astronomy, University of British Columbia, Vancouver, BC, CANADA, [3]Department of Computer Science, Otto von Guericke University of Magdeburg, Magdeburg, GERMANY, [4]Vancouver Coastal Health, Vancouver, BC, CANADA.

Aim: Accuracy of absorbed dose calculations in personalized radionuclide therapy is directly related to the accuracy of activity estimates obtained at each of imaging time-points. Our objective was to compare the accuracy of ^{177}Lu quantification achieved using two scatter correction (SC) methods: 1)triple energy window (TEW) and 2)analytical photon distribution interpolated (APDI). Materials and Methods: Four series of experiments were performed using objects filled with ^{177}Lu: (a) seven spheres [0.5-113mL] were scanned in air, and in a cylinder filled with cold and hot water; (b) six bottles [8.5-34mL] in air and hot water, (c) four bottles [33.9mL] in a Thorax phantom filled with water (lungs and spine inserts, and additional beef bone created non-uniform density distribution), (d) four bottles [34-200mL] in air and between four 2L water bags. SPECT/CT SymbiaT (Siemens-Healthcare) camera with MELP collimator, and three energy windows were used (208keV photopeak and two scatter windows). OSEM reconstruction included attenuation correction (AC) and resolution recovery (RR), and either TEW or APDI. Segmentations for objects in air and in cold water used fixed thresholds of 0.1% and 1%, respectively, while for hot background, a fixed 40% threshold and our iterative adaptive dual thresholding (IADT) method were used. Four additional scans (six objects [17-200mL] placed in a cylinder with four different backgrounds) were performed to create an IADT calibration curve. Results: For objects placed in cold uniform-density backgrounds (air, water) the accuracy of activity quantification was similar for both SC methods. Depending on object size and shape the errors ranged from 3-6% in air to 10-12% in water. Although in scans of objects placed in hot background the accuracy of total activity reconstruction was about 6%, the quantification of individual objects was highly dependent on their sizes and segmentation method. When using IADT segmentation the errors ranged from 3% for large objects to over 30% for small spheres, using 40% fixed threshold resulted in larger errors. For objects placed in non-uniform-density background the APDI method outperformed TEW by a factor of three. Conclusion: For areas with uniform density (majority of clinical situations), similar levels of activity quantification of ^{177}Lu can be achieved when using TEW or APDI scatter correction (SC). Phantom experiments showed that for objects ≥34ml, activity can be reconstructed to within 10%. APDI outperforms TEW in non-uniform-density areas (e.g. a tumor close to the spine), but is more complex and requires more computer time than TEW.

OP386

Towards a quality assurance for dosimetry in peptide receptor radionuclide therapy (PRRT) with 177Lu-DOTATATE

G. Marin, B. Vanderlinden, Z. Wimana, T. Guiot, I. Karfis, P. Flamen; Institut Jules Bordet, Bruxelles, BELGIUM.

Aim177Lu-DOTATATE is the most commonly used radiopeptide for PRRT. In order to establish a reliable dose-response/toxicity correlation it is necessary to achieve a good

precision on all measurements. The aim of this work was to evaluate the precision of the dosimetric procedure.Materials and methodsEight patients with neuroendocrine tumors received 4 to 5 cycles of 177Lu-DOTATATE. Three SPECT/CT (4, 24, 168h post-injection) and five blood samples (0, 1, 4, 24, 168h post-injection) were performed after each administration. Organs activities were calculated by multiplying the volumic activities by the manually delineated CT volumes. Time-activity curves (TAC) were obtained by fitting measured activities with biexponential functions. Residence times (RTs) were obtained by integrating the TACs.To avoid inter-patient variability, RTs and volumes were normalized by the respective mean value of each organ for all cycles for each patient (mean normalized value = 1).The precision of RTs and volumes was evaluated with the standard deviations of the normalized RTs (nRTSDs) and normalized volumes (nVSDs) for each organ. As those SDs still contain both stochastic quantification errors and intra-patient inter-cycle variability, their analysis will help discriminate between the two.ResultsFor kidneys, nRTSDs of 0.14 and 0.10 were found respectively for the right and left. A linear correlation (R^2 = 0.78) was found between the nRTSDs of each pair, suggesting that nRTSDs are not completely explained by quantification errors.For the spleen, a higher nRTSD of 0.18 was found, partly due to diurnal volume modification because of the dynamical status of splenic blood supply, as highlighted by a nVSD of 0.14 for spleen versus 0.04 for kidneys.For the liver, nRTSD was 0.22. Two patients showed a systematic RT decrease over therapy cycles (corresponding to decreasing lesion uptake). When they were discarded from the evaluation, the liver nRTSD decreased to 0.08.For the total body, the higher nRTSD (0.21) may come from low image statistic.For the bone marrow, a different quantification procedure based on blood samples lead to a nRTSD of 0.19.ConclusionOrgans nRTSDs allowed estimation of the maximum stochastic errors on dose quantification in PRRT. Intra-patient variability was shown to be a source of overestimation, but can be reduced with a quality assurance program driven by error analysis. This will help identify methodological sources of error requiring additional quality control, leading to better precision on dose-response/toxicity correlations.

OP387

International Multicentre Evaluation of Absolute Quantification in Planar and SPECT Imaging

B. E. Zimmerman[1], I. Buvat[2], E. C. Frey[3], A. J. Green[4], D. Grošev[5], M. Lassmann[6], M. Ljungberg[7], **G. Poli**[8]; [1]National Institute of Standards and Technology, Gaithersburg, MD, UNITED STATES, [2]Service Hospitalier Frédéric Joliot, Paris, FRANCE, [3]Johns Hopkins Medical Institutions, Baltimore, MD, UNITED STATES, [4]National Physical Laboratory, Teddington, UNITED KINGDOM, [5]University Hospital Centre Zagreb, Zagreb, CROATIA, [6]Universitatsklinik Wurzburg, Würzburg, GERMANY, [7]Lund University, Lund, SWEDEN, [8]International Atomic Energy Agency, Vienna, AUSTRIA.

Aim: Accurate quantitation of activity provides the basis for internal dosimetry of targeted radionuclide therapies. The International Atomic Energy Agency has recently conducted a Coordinated Research Project entitled “Development of Quantitative Nuclear Medicine Imaging for Patient Specific Dosimetry”. The main purposes of this project were to investigate the quantitative imaging capabilities at sites with a variety of experience and equipment and to assess the levels of errors in activity quantitation resulting from the use of SPECT and planar imaging. Materials and methods: Participants from 10 countries took part in the intercomparison by quantifying activities using planar, SPECT and SPECT/CT imaging. Participants were provided with four epoxy-filled cylinders containing 133Ba, chosen as a surrogate for 131I. The 133Ba sources, with nominal volumes of 2, 4, 6 and 23 mL, were calibrated by the U.S. National Institute of Standards and Technology, with the activity unknown to the participants. The sources were imaged in a cylindrical phantom filled with water. In a first trial, participants estimated the activities using local protocols. In the second trial, participants repeated the measurements using a standardized protocol, with acquisition and processing methods more rigorously defined. Finally, processing and analysis of the data from the second trial was repeated centrally. Results: In the first trial, true activities were underestimated by 15-20% with planar imaging, after rejection of outlying data. SPECT with Chang’s attenuation correction data showed the highest variability and the true activity was underestimated by 5-10%. SPECT/CT gave the best accuracy and reproducibility in all trials. The second trial showed some improvements in accuracy, variability and outlying results. Planar imaging was subject to methodological errors, e.g., in the use of a transmission scan for attenuation correction. The use of Chang attenuation correction (AC) was essential for SPECT without CT-based AC, and variability resulted from definition of phantom contours.Conclusion: The project demonstrated the need for training and standardized protocols to achieve good levels of quantitative accuracy and repeatability in a multicentre setting. Absolute quantification of simple objects with no background activity was possible with errors of +8 % with planar imaging, -7 % with SPECT (with Chang-AC) and better than 6 % for SPECT/CT. CT-based AC was the best, and in a clinical scenario would handle uniform and non-uniform attenuation distributions. Processing for SPECT/CT was more

standardized and less subject to errors and therefore seems the best option for quantitative nuclear medicine imaging.

Insights into the DNA damage response can improve peptide receptor radionuclide therapy outcomes

J. Nonnekens, C. Beerens, M. van Kranenburg, D. C. van Gent, M. de Jong; Erasmus MC, Rotterdam, NETHERLANDS.

Aim: The targeted treatment of neuroendocrine tumors (NET) with lutetium-labeled somatostatin analogues (peptide receptor radionuclide therapy, PRRT) is successfully applied in clinical trials, while similar approaches may also be feasible for many other tumor types. PRRT of metastasized NETs is very promising with improved patient outcome compared to other treatments, but cure is reached only in very low percentages. To achieve an even better tumor response, the administrated dose cannot simply be increased because of dose limiting toxicity in bone marrow and kidneys. Therefore, in order to improve the current treatment outcome, we investigated the DNA damaging effects of PRRT with the final aim to enhance these effects through modulation of the DNA damage response. We aim specifically to sensitize the (fast replicating) tumor cells without further damage to healthy tissues using PARP inhibitors. Materials and methods: All experiments were performed with rat pancreatic CA20948 tumor cells expressing the somatostatin receptor subtype 2 or human tumor cells lines stably transfected with this receptor subtype. Cells were incubated for 4 hours with increasing doses of ^{177}Lu-[DOTA, Tyr^3]octreotate (DOTA-TATE), followed by non-radioactive chases for different periods until 5 days post treatment. Cells were fixed and fluorescently stained with different antibodies (53BP1, gamma-H2AX) to visualize the accumulation of DNA repair proteins to the produced DNA double strand breaks. Cell proliferation was measured using EdU incorporation and Click-iT labeling technology. Simultaneously, cells were incubated during the chase period with the PARP inhibitor Olaparib. Furthermore, cells were subjected to different doses of ^{177}Lu-DOTA-TATE in the absence or presence of Olaparib and cellular survival was measured using colony assay and sulforhodamine B colorimetric assay. Results: Cells treated with ^{177}Lu-DOTA-TATE showed accumulation of 53BP1 and gamma-H2AX in so-called foci, indicating the production and repair of DNA double strand breaks. Foci were visible up to 3 days after treatment. Interestingly, addition of Olaparib led to increased and prolonged DNA damage, specifically in replicating cells. ^{177}Lu-DOTA-TATE eradicated cells in a dose dependent manner and cell killing was enhanced by Olaparib. Conclusions: PRRT produced DNA single and double strand breaks and triggered the DNA damage response in our in vitro models. Through modulation of the DNA damage response with Olaparib, we were able to enhance the DNA-damaging effects of PRRT, specifically in replicating cells. We expect that our results will eventually improve the current PRRT outcome, leading to increased patient survival rates.

OP389

Blocking DNA repair mechanism - the way to improve alpha targeted therapy of glioblastoma multiforme ?

E. Rosiak[1], H. Koziara[2], R. Matyskiel[1], B. Królicki[2], L. Królicki[1]; [1]Department of Nuclear Medicine, Medical University of Warsaw, Warsaw, POLAND, [2]Department of Neurosurgery, Maria Skłodowska-Curie Memorial Cancer Center and Institute of Oncology, Warsaw, POLAND.

AIM: Recently the alpha targeted therapies using intracranial delivery of 225Ac or 213Bi-labeled Substance P (SP) have been developed. Our aim was to investigate the radiobiological effects of alpha-particles from 213 Bi and 225Ac- on cell survival, cell cycle progression and DNA ploidy in glioblastoma multiforme (GBM) cells cultured in vitro under hypoxia and normoxia condition.MATERIALS: Cultured cells in vitro were obtained from tumor samples from 43 patients with histologically confirmed of GBM. They were treated with 1 dose of 1,2MBq 213 Bi-SP/1ml medium or 1 dose of 180kBq 225Ac-SP/ 1ml medium under normoxia and hypoxia (0,7-0, 8% O2). Non-irradiated cancer cells cultured under normoxic and hypoxic condition were used as a control. METHODS: The level of apoptosis and necrosis, measurement of cellular DNA content and the analysis of the cell cycle we performed by flow cytometry under aerobic and hypoxic conditions. Experimental data was obtained at 1 h, 3 h, 6 h, 12 h, 24 h, 48 h, 72 hours and 10 days after application of isotopes for cell cultures. RESULTS: Alpha radiation induced cell cycle alterations. Between 24 - 72 hr after the treatment with 213 Bi-SP and 225Ac-SP under normoxia during S-phase cycle were 100%± 0.0% and 99.9%±0.12 % cells; under hypoxia during S-phase were 99.88 %± 0.29% cells and 100%± 0% cells respectively. 72 hours after treatment with 213 Bi-SP and 225Ac-SP under hypoxia and normoxia we observed enhanced self-renewal of cancer cells, DNA repair and significantly decreased the population of cells in S phase with accumulation of cells in G2/ M phase as well as radiation-induced chromosomal damage, alterations in the structure and number of chromosomes with high levels of tetraploidy or

aneuploidy.10 days after treatment with 213 Bi-SP and 225Ac-SP the ratio of G2/G1 cells increased significantly compared to control cells: under normoxia ratio of G2/ G1 was 8.13%±4.38% and 9.33%±5.0%; under hypoxia ratio of G2/ G1 was 10.72%±2.90% and 11.02% ±3.10% respectively ($p<0.05$)CONCLUSION: These results suggest that alpha therapy induces DNA damage that are reflected in transient arrest in S-phase up to 72 hours under hypoxic and normoxic condition. This response can however be reduced by the activities of DNA repair pathways observed after 72 hours. Alpha targeted therapy combined with blocking DNA repair mechanisms could be therefore offer as a therapeutic strategy for glioblastoma multiforme and further research will be needed.

OP390

Radiation-Induced Media-Transferred Bystander Effect in Breast Cancer Cells

K. L. Madsen, P. F. Høilund-Carlsen, B. B. Olsen; Odense University Hospital, Odense, DENMARK.

Aim: In radiation biology, the term *bystander effect* refers to the phenomenon that non-irradiated cells exhibit similar changes as nearby irradiated cells, e.g., DNA double strand breaks (DSBs), chromosomal instability, and cell death. The aim was to investigate if this bystander effect could be media-transferred to non-irradiated cells by incubation in irradiated cell conditioned medium (ICCM). Material and methods: Human breast cancer MCF-7 cells in medium were irradiated with 0, 1, 2, 4 or 8 Gy of external ionizing radiation. After 24 h, the ICCM was transferred to a new series of non-irradiated MCF-7 cells to examine for a potential medium-transferred bystander effect using three different endpoints: i) DSBs visualized by γH2AX-foci after 18 h incubation with ICCM, ii) number of micronuclei in binuclear cells as a marker of chromosomal instability after 48 h of incubation with ICCM, and iii) the effect on cell death after 7 days of incubation with ICCM as judged by the CellTiter-Blue Viability Assay, which measures metabolic activity. Results: Re i: DSBs were induced in the non-irradiated cells since the average number of γH2AX-foci pr. cell was significantly increased independent of radiation dose; 0 Gy 0,5±0,8, 1 Gy 1,7±1,6 ($P < 0,001$), 2 Gy 1,3±1,4 ($P < 0,01$), 4 Gy 2,7±2,7 ($P < 0,0001$) and 8 Gy 3,9±3,5 ($P < 0,0001$). Re ii: The number of micronuclei in binuclear cells was negligible with only a small and insignificant increase upon incubation with ICCM, suggesting the absence of chromosomal instability. Re iii: There was no cell death upon incubation with ICCM; on the contrary, stimulating effects were observed on the metabolic activity independent of radiation dose; 0 Gy 100%±3,1, 1 Gy 111%±2,0 ($P < 0,01$), 2 Gy 117%±1,0 ($P < 0,001$), 4 Gy 117%±1,4 ($P < 0,001$) and 8 Gy 108%±2,6 (not significant). Conclusion: There was a significant radiation-induced medium-transferred bystander effect with respect to DSBs, but chromosomal instability was not significant in non-irradiated cells incubated in ICCM. In addition, a somewhat surprising and significant increase in metabolic activity was observed. This apparently paradoxical increase warrants further experiments.

OP391

Ex vivo tumor tissue culture to mechanistically examine DNA-damage after peptide receptor radionuclide therapy

J. Nonnekens, C. Beerens, D. C. van Gent, M. de Jong; Erasmus MC, Rotterdam, NETHERLANDS.

Aim: Many studies to explore cellular mechanisms of anticancer therapies are performed on cell lines. However, morphology, complexity and key parameters of actual tumors differ considerably from cell lines grown in 2D culture. Moreover, tumors from different patients differ in their response to therapy, necessitating personalized treatment. To take analysis of anticancer therapies to the next level, we have developed a novel system to examine human tumor tissue *ex vivo*. Specifically, we examined patient neuroendocrine tumors (NETs) that will be treated with lutetium-labeled somatostatin analogues (peptide receptor radionuclide therapy, PRRT). This approach allows for detailed analysis of the cellular responses, such as the DNA damage response, over prolonged periods of time in the relevant tumor context. Materials and methods: Fresh human tumor tissue derived from surgery or biopsies was cut in thin slices (300 μm) with a Leica vibrotome. Culturing of NET-slices was performed at 37°C on a rotating platform (60rpm). Besides using human tumor tissue, xenografted neuroendocrine tumors grown on mice were used. These slices were grown on cell strainer inserts at 37°C. Slices were incubated for 4 hours with various doses of ^{177}Lu-[DOTA,Tyr^3]octreotate (DOTA-TATE), followed by non-radioactive chases for different periods. Slices were formalin fixed and paraffin embedded. 4m paraffin sections were subjected to immunohistochemical stainings: hematoxylin and eosin staining for morphology and fluorescent staining with different antibodies (53BP1, gamma-H2AX) to visualize the accumulation of DNA repair proteins to the produced DNA double strand breaks. Cell proliferation was measured using EdU incorporation and Click-iT labeling technology. Cell death was measured using apoptotic TUNEL labeling. Results: In the current settings, the tissue slices could be kept alive for approximately 1 week after dissection. Cells of slices treated with ^{177}Lu-DOTA-TATE showed foci formation of 53BP1 and gamma-H2AX, indicating the production of DNA double strand breaks, up to for several days after

treatment. Furthermore, the treatment reduced replication and induced apoptosis. Conclusions: PRRT produced DNA double strand breaks and triggered the DNA damage response in NET tumor slices. These results give mechanistic insights into the effectiveness of PRRT. We will apply this knowledge to improve the current PRRT-protocols and increase patient survival rates. Furthermore, looking from an animal welfare aspect; the use of tissue slices as an intermediate step between *in vitro* cell assays and *in vivo* mouse experiments will tremendously reduce the amount of laboratory animals needed.

OP392

Clinical Relevance of Targeting SSTR2, GRPR and CXCR4 with Radioligands for Imaging and Therapy in Breast Cancer

S. Dalm, A. Sieuwerts, M. Look, M. Melis, C. van Deurzen, J. Foekens, M. de Jong, J. Martens; Erasmus MC, Rotterdam, NETHERLANDS.

Introduction: Imaging and therapy using radioligands targeting receptors expressed on cancer cells is successfully being used in patients with neuroendocrine tumors. Previous studies have demonstrated expression of the somatostatin receptor subtype 2 (SSTR2), the gastrin releasing peptide receptor (GRPR) and C-X-C chemokine receptor 4 (CXCR4) on breast cancer (BC). Since GMP-compliant radioligands targeting the SSTR2, GRPR and CXCR4 are available, targeting these receptors on BC might offer new imaging and therapy options. BC is a heterogeneous disease consisting of multiple molecular subtypes, which influence treatment and prognosis. We investigated the SSTR2, GRPR and CXCR4 mRNA levels of 915 BC patients and correlated this with important clinico-pathological factors and prognosis. Materials and Methods: SSTR2 and GRPR expression of 13 clinical BC specimens was analyzed by in vitro autoradiography using ^{111}In-Octreotate and ^{111}In-AMBA, respectively, and correlated with corresponding mRNA levels. Moreover, SSTR2, GRPR and CXCR4 mRNA levels of 915 BC specimens (from lymph node negative (LNN) and lymph node positive (LNP) patients) were determined using RT-qPCR and associated with known clinico-pathological factors (total patient group) and prognosis (LNN patients). Results: A significant positive correlation was found between binding of ^{111}In-Octreotate and ^{111}In-AMBA to the BC specimens and SSTR2 (Rs=0.7348, P=0.0042) and GRPR mRNA levels (Rs=0.9352, P<0.0001), respectively. Furthermore, in the total patient group high SSTR2 and high GRPR mRNA levels were both associated with estrogen receptor (ER) positive (P<0.0001) and progesterone receptor (PR) positive tumors (P<0.0001). On the contrary, high CXCR4 mRNA levels were associated with ER negative tumors (P<0.0001). No association was found between SSTR2 and GRPR expression and prognosis in the untreated LNN patients. Contrary to what expected, higher CXCR4 expression was associated with better prognosis in the LNN patient group (Hazard ratio metastasis free survival=0.76 (0.64-0.90), P=0.001). Conclusion: SSTR2 and GRPR mediated imaging can be applied in ER and PR positive tumors, while CXCR4 mediated imaging is best suited for ER negative tumors. Thus, ER positive patients resistant to current standard lines of therapy might benefit from radioligands targeting SSTR2 or GRPR, while in progressing ER negative patients CXCR4 therapy might be considered, particularly those patients whose lesions are demonstrated positive based on imaging using the respective ligands.

OP393

Increase of PSMA Expression by Androgen Deprivation

B. Meller, C. O. Sahlmann, S. Hijazi, C. Bouter, L. Trojan, J. Meller, P. Thelen; Georg-August-University Göttingen, Göttingen, GERMANY.

Aim: PSMA is novel and promising target for diagnostics and therapy of prostate carcinoma (PC). The aim of this investigation was to increase PSMA-expression for improved detection of recurrent PC and its metastases in diagnostics as well as better targeting for radiopeptide-therapy by use of standard PC drugs. Material & Methods: Radiolabeling of 5 μg PSMA-HEBD-CC (ABX) were performed with M = 1200 MBq $^{68}GaCl_3$ (iThemba Labs) in a GRP Module (Scintomics). The human castration resistant cell line VCaP (CRPC) was obtained from ATCC. Parallel cultures were treated with 1 nM testosterone and with 5 μM abiraterone over 48 h. The androgen sensitive cell line (revCRPC) was long-term sub-cultured with 1 nM testosterone. Parallel cultures were incubated without testosterone or received additionally 5 μM abiraterone acetate for 48 h. To assess the capacity of cells for the labeled compounds, 0.3 nM ^{68}Ga-labeled peptide (100-300 kBq/ml) was simultaneously applied to 3 parallel cells cultures for each interval (1 - 3 hours) and each cell line. Experiments were repeated for three times. Cells were harvested and measured activity was correlated to the cell count. Additionally, PSMA-mRNA expression was investigated by qPCR. Results were statistically evaluated by non-parametric tests. Results: Androgen sensitive cells (revCRPC) accumulated the tracer significantly higher than the castration resistant subtype (CRPC, p<0.05). ^{68}Ga-PSMA-HEBD-CC uptake almost doubled during 3 h in all cell lines (p<0.01). Compared to non-treated cells in parallel cultures the pre-incubation with abiraterone over 48 h resulted in a significant increased uptake in CRPC (p<0.001). In revCRPC pre-incubation with abiraterone resulted in an eight-fold higher uptake after 3h. Withdrawal of medium supplementation testosterone additionally increased the uptake up to ten-fold (p<0.01). The influence of abiraterone on PSMA-expression was confirmed by PCR

data in both cell lines. Conclusions: We found an increasing uptake of ^{68}Ga-PSMA-HEBD-CC over time, probably based on an increasing internalization rate. Our investigations verify an increase of PSMA-mediated uptake by androgen deprivation in CRPC and androgen sensitive cell lines. These results might be useful in the early detection of PC recurrence as well as for PSMA-mediated therapy. These results may contribute to the development of improved protocols in PSMA-mediated imaging and therapy sequencing.

OP394

Detrimental Effects of Radiation on the Fluorescence of Fluorophores: Implications for Dual-Modality Imaging

R. Hernandez[1], S. Heskamp[2], M. Rijpkema[2], D. M. Goldenberg[3], W. McBride[3], A. Morgenstern[4], F. Bruchertseifer[4], W. Cai[1], O. Boerman[2]; [1]University of Wisconsin-Madison, Madison, WI, UNITED STATES, [2]Radboud University Medical Center, Nijmegen, NETHERLANDS, [3]Immunomedics Inc., Morris Plains, NJ, UNITED STATES, [4]Institute of Transuranium Elements, Karlsruhe, GERMANY.

Aim: Despite the large interest on nuclear/optical multimodality imaging, the effect of radiation on the fluorescence properties of fluorophores remains unknown. Herein we determined the radiosensitivity of the near infrared dye IRDye800CW, and devised a strategy to ameliorate its negative impact for multimodality imaging. Materials and Methods: Buffered aqueous solutions of IRDye800CW were incubated in the presence of increasing activities of ^{111}In, ^{68}Ga, or ^{213}Bi (γ, β, and α emitter, respectively) and its normalized fluorescence (λ_{ex}=740 nm and λ_{em}=796 nm) was determined at different radiation exposure times. The radioprotective effect of three hydroxyl radical scavengers (ethanol, gentisic acid, and ascorbic acid (AA)), was examined. The impact of other factors such as activity concentration, temperature, type of buffer, and pH on the fluorescence properties of IRDye800CW was also determined. Similar experiments were conducted on RDC018, a DOTA-conjugated IRDye800CW-derivative used as multimodality imaging probe in pretargeting. Results: A significant decrease of the fluorescence of IRDye800CW was observed upon incubation with escalating activities of ^{111}In, ^{68}Ga or ^{213}Bi. The effect was dependent on the amount of activity as well as the type of radiation, which supported our hypothesis of a free radical mediated mechanism. ^{68}Ga showed the largest radiolytic effect - the fluorescence signal of the fluorophore was reduced to background levels within 30 min incubation with 20 MBq of ^{68}Ga-, followed by ^{111}In and ^{213}Bi. IRDye800CW and RDC018 presented similar radiosensitivity except for ^{213}Bi-labelled RDC018, which exhibited enhanced radiolysis, presumably due to direct radiation damage induced by α particles. The addition of scavengers provided a concentration dependent radioprotective effect. Among all scavengers, AA provided the most robust protection over a wide range of concentrations and preserved RDC018 fluorescence at much higher activity levels. Interestingly, AA afforded only partial radioprotection of ^{213}Bi-RDC018, which further supported our hypothesis of α particle-fluorophore direct interaction. Conclusion: Herein we provide the first report on the radiosensitivity of fluorophores, and outline a set of conditions that minimize the deleterious effects of radiation damage on nuclear/optical multimodality imaging probes.

OP395

Characterisation and quantification of fluorescently labeled Exendin for beta cell targeting and comparison with radiolabeled Exendin

S. Ekim, D. Bos, M. Brom, M. Gotthardt; Radboud University Medical Centre, Nijmegen, NETHERLANDS.

Background and aims: Exendin can specifically bind to the glucagon-like peptide 1 receptor (GLP-1R) which is expressed on the beta cells in the pancreas. By targeting GLP-1R with radiolabeled Exendin, it is possible to determine the beta cell mass. However, the resolution of PET and SPECT is not sufficient to examine tracer accumulation at the cellular level, which could provide vital information about the specificity of the tracer for beta cells. By using fluorescent labeled tracers, it is possible to study the kinetics of radiotracer accumulation at the cellular level. But quantification of the fluorescently labeled tracers is difficult because of the limited penetration depth of the fluorescent label and attenuation/absorption and autofluorescence of organs. The aim of the study is developing a sensitive and quantitative technique to measure accumulation of fluorescently labeled tracers, comparing the biodistribution of fluorescent labeled Exendin with radiolabeled Exendin and evaluation of the effect of peptide dose for both tracer.Materials and methods: GLP-1R over-expressing CHL cells were used in experiments. For in vitro experiments 30nM Exendin-3-Cy5.5(Ex-Cy5.5) was incubated at 37°C degrees for 4 hours, and blocking experiment with an 30 fold molar excess unlabeled Exendin-3 was performed in 3 separate wells. The cell-bound fluorescence was measured with ELISA-plate reader.Ex-Cy5.5 and Exendin-3-DTPA-^{111}In(Ex-DTPA-^{111}In) biodistribution studies were performed in BALB/c nude mice with a subcutaneous CHL-GLP1R tumor. Mice were injected with 0,3-1-3-10μg of Ex-Cy5.5 or Ex-DTPA-^{111}In and after 4 hours the organs were dissected and homogenized for fluorescence measurements. Samples are measured in ELISA plate reader with organ

specific standards.Results: Binding assay performed on CHL-GLPl R(+) cells showed that Ex-Cy5.5 can specifically bind to GLP1R at a percentage of 17% which is similar to Ex-DTPA-^{111}In. The uptake of Ex-3-Cy5.5 in the tumor was 8, 49±3,99 %lD/g when 0,3μg was injected and maximum relative uptake was observed at 1μg (21,04±6,35 %lD/g). With higher doses lower tumor accumulation was observed.Conclusion: A very sensitive and quantitative technique for biodistribition studies of fluorescently labeled peptides was developed.By preparing organ specific standard curves, fluorescence signal detected from the organs could be accurately quantified. The results showed that the optimal dose for in vivo targeting of the GLP-1R with Ex-Cy5.5 and Ex-DTPA-^{111}In is different. This should be taken into account while using the fluorescently labeled tracers to study the kinetics of radiotracer accumulation. ln vivo optimal dose for Ex-Cy5.5 is observed as 1μg, while for Ex-DTPA-^{111}In it is observed as 0,3μg.

Adaptation of 13N-NH3 and 18F-FDG Imaging Protocols for sarcoidosis for new scanner technology

C. Abreu[1], J. O'Doherty[1], S. Barrington[1], S. Pereira[1], L. Alves[1], J. John[1], P. Schleyer[2]; [1]PET Imaging Centre, King's College London, King's Health Partners, St Thomas' Hospital, London, UNITED KINGDOM, [2]PET Imaging Centre, King's College London, London, UNITED KINGDOM.

Background. Perfusion 13N-NH3 and 18F-FDG viability studies are performed as combined investigations to assess for possible cardiac sarcoidosis. At our centre we perform a 1-day protocol beginning with a dynamic rest 13N-NH3 (550 MBq) scan using quantitative Patlak analysis and visual analysis followed by an 18F-FDG cardiac scan at 30 minutes and a half body scan at 60 minutes post injection. Recently we have installed 2 new GE Discovery 710 PET CT scanners, and have subsequently adapted our imaging protocol to capitalise on the new techniques available on these scanners. Methods. We performed 14 patient scans for suspected cardiac sarcoidosis on a Discovery 710 PET/CT scanner. The new imaging protocol was compared with that from our previous scanner (GE Discovery VCT). The D-710 is different in terms of crystal material (LYSO vs BGO), acquisition mode (3D only), image reconstruction and ultra low dose CT for attenuation correction (Q.AC). ECG gating was performed on all 18F-FDG images, and respiratory motion correction was also evaluated. Average cine CT images were used for attenuation correction to reduce respiratory motion induced by PET/CT misalignment. Further manual alignment was also required for some patients. Results. Patient radiation exposure for the cine CT was reduced using the Q.AC CT reconstruction algorithm by a factor of 2.18 in both DLP (103.59 to 47.56) and CTDIvol. (6.47 to 2.97). Image quality was felt to be improved compared to the D-VCT. Radiation dose due to CT attenuation correction is markedly reduced using the new scanning technology. Further improvements to flow quantitation may be made by using compartmental modelling instead of Patlak analysis. Conclusion. Installation of new PET/CT scanners enabled a significant change in cardiac acquisition protocol, which improves image quality, reduces radiation dose and can provide a more accurate CT registration for attenuation correction. It may be possible to further reduce patient dose by lowering the administered 13N-NH3 activity without compromising image quality due to the increased sensitivity of the D-710 compared to the D-VCT.

OP412
Benign Iodine-131 Treatment - Passing tasks from physician to technologist

H. C. Larsen, L. F. Grønnemark, P. C. Holdgaard, MD; Department of Nuclearmedicine, Vejle Hospital - Part of Lillebaelt Hospital, Vejle, DENMARK.

AIM: In Departments of Nuclear Medicine in Denmark the benign Iodine-131 treatment is most often given by a physician. Furthermore the physician gives the information about the treatment to the patients. Previously at our department the physician gave the information about the benign Iodine-131 treatment to

each patient individually, including the precautions and possible side effects. The physician used an entire working day performing this procedure. The purpose of this project was to pass some of the tasks from the physician to the technologists, and thereby save physician time and give more responsibility and new skills to the technologists. Methods and materials: In a period of 2 months the task of giving information to the patients was handed over from the physicians to 2 technologists. We also changed it to a common information session held by the technologist for all the patients scheduled that day instead of the physician gave the information individually to each patient. The first common session were held by the physician and 2 technologists observed. After a while, it was one of the technologists who did the common session, observed by the physician. Finally when the technologists were familiar with the common session, one of the 2 technologists did the session alone. Results: Now the common information session is held by the technologist about the precautions and possible side effects to the benign Iodine-131 treatment and other practical information. The session lasts 20 minutes and often includes 8 patients. Doing the information session the patients are allowed to ask questions and this might benefits the other patients. The physician has a short individual conversation with each patient after the common session. The physician still makes palpate the thyroid gland and decides the Iodine-131 dose. The individual conversation takes 5-10 minutes per patient. Before the setup was changed the physician spend an entire working day giving information to the Iodine-131 patients. Now the physician only spends 2-3 hours talking with the Iodine-131 patients. Conclusion: By doing a common information session and by passing some of the tasks in benign Iodine-131 treatment from the physician to the technologist it is possible to considerably reduce the use of physician time, which then can be allocated to other tasks. Additionally it gives the two technologists more responsibility and additionally skills, better understanding of this patient group and thereby a more meaningful workday.

OP414

Methods for preparing and acquiring PET/CT exams with 18F-Fluorodeoxyglucose and 18F-Fluoromethycholine

R. Sanco, M. Zappalà, V. Arnoldo, L. Memo, E. Zaramella, A. Carraro, L. Evangelista; Istituto Oncologico Veneto I.R.C.C.S., PADOVA, ITALY.

Introduction. To date, the standardization of protocol for preparation and acquisition of PET/CT images with 18F-Fluorodeoxyglucose (FDG) and 18F-Fluoromethylcholine (FCH) are missed. Because both the examinations are functional, the patient preparation is critical. The aim of the present prospective study was to determine the effect of patient preparation on PET image quality, both visually and semiquantitatively. Materials e methods. We collected data from 87 patients: 60 underwent FDG PET/CT and 27 performed a FCH PET/CT. Each patient was asked to compile a questionnaire that was based on food information, such as the type and the amount. Moreover, technician data (i.e. true, random and single coincidence, tracer dose, injection and acquisition time) and semiquantitative features (such as maximum and mean Standardized Uptake Value-SUVmax and SUVmean-, and Standardized Uptake Lean Value-SUL) were collected and correlated with clinical and demographic parameters. T-Student test and ANOVA test were used for the statistical analysis. Results. In 60 patients undergoing FDG PET/CT, a higher singles coincidence rate was found in case of a fasting >10h as compared to a fasting ranged between 5-10h (43.8 ±5.7 x105 vs. 37.8±6.7x105; p=0.028). Moreover, the rate of random and true coincidences was higher in patients with a body weight (BW)>60 kg and in those who had a water consumption >1liter before scan. At semiquantitative analysis, patients with a body mass index (BMI) >25 showed a significantly higher liver SUVmax and SUVmean than those with a BMI60kg than those with a BW<60kg, although not statistically significant. None of clinical parameters was associated with semiquantitative data (SUVmax and SUVmean of liver and kidney). Finally, we found that the bowel FCH uptake was visually inferior in patients with a BMI<25 than those with a BMI>25 (p=0.025). Conclusions. To improve the quality of FDG and FCH PET images seems necessary to prepare the patient as following: 1) to prolong the fasting time (>10 hours) before the examination; 2) to avoid the assumption of carbohydrate the evening before PET exams (to improve cardiac evaluation; especially in case of thoracic disease) and 3) to invite to drink at least 1 liter of water before the examination.

OP415

SPECT Myocardial Perfusion Imaging Quantification in Obese Subjects: Influence of Attenuation Correction with Computed Tomography Attenuation Maps

O. Stakhiv[1], M. Clarke[2], M. Aplin[2], N. Singh[2], K. Day[2], S. Dizdarevic[2], M. Jessop[2], E. Sousa[1]; [1]Escola Superior de Tecnologia da Saúde de Lisboa, Instituto Politécnico de Lisboa, Lisbon, PORTUGAL, [2]Nuclear Medicine, Department of Imaging, Brighton and Sussex University Hospital NHS Trust, Brighton, UNITED KINGDOM.

Introduction: Myocardial Perfusion Imaging (MPI) is a well implemented technique for assessment of Coronary artery disease (CAD. Obese subjects have a larger volume of soft tissue and organs that attenuate gamma causing false positive results due to attenuation artefacts. Aim: To evaluate the Influence of attenuation correction with Computed Tomography Attenuation Maps

(CTAM) in perfusion quantification for subjects with Body Mass Index (BMI) between 30 and 35, and above 35. Methods: Four groups of 72 subjects 47 with BMI between 30 and 35 Kg/m2 (27 male (GMI) and 20 female (GFI)) and and 24 (13 male (GMII) and 11 female (GFII)) with BMI between 30 and 35 Kg/m2 above 35 Kg/m2 who underwent stress-rest, SPECT MPI of a two days protocol, by EANM guidelines protocol with activity adjusted to subject's mass (400 MBq for subjects 110 kg), with 99mTc-tetrafosmin, for suspected CAD, were analysed with and without the incorporation of CTAM, for stress and rest studies, the studies were reconstructed by OSEM/MLEM. All images segmentation and quantification was done by myocardial walls regions for perfusion: Anterior (Ant), Inferior (Inf), Lateral (Lat), Septal (Sep) and Apical (Api), recurring to QGS/QPS. Each study was processed three times by one operator, and average value was used. For statistical evaluation it was used Friedman test for nom parametrical pared samples. Results: Statistically significant differences were found in comparison of studies with and without attenuation correction for: GFI group of stress and rest studies respectively for Lat ($p=0.006$, and $p=0.034$), Inf ($p=0.000$, and $p=0.000$) and Sep ($p=0.074$, and $p=0.044$); GFII group in stress study in Lat ($p=0.073$) and in stress and rest studies respectively for inferior wall ($p=0.001$, and $p=0.008$); GMI group of stress and rest studies respectively for Lat ($p=0.000$, and $p=0.000$), Inf ($p=0.000$, and $p=0.000$), Sep ($p=0.003$, and $p=0.001$) and for rest study in Api ($p=0.045$). GMII group of stress and rest studies respectively for Lat ($p=0.020$, and $p=0.014$), Inf ($p=0.000$, and $p=0.000$), Sep ($P=0.003$ and $p=0.075$). A significance level of 5% was used. Discussion: The influence of attenuation correction with CTAM is bigger within the groups with BMI between 30 and 35 Kg/m2, for male and female. This influence is also seen more markedly in the male groups. Conclusion: Differences between the male and female sets, agree with the ones described in literature.

OP416

[18F]-FDG SUV of reference regions in PET/MRI following standard MR-based attenuation correction

I. Haidinger[1], I. Rausch[1], M. Mayerhöfer[2], M. Hartenbach[3], T. Beyer[1]; [1]Centre for Medical Physics and Biomedical Engineering, Medical University of Vienna, Vienna, AUSTRIA, [2]Division of Radiology, Department of Biomedical Imaging and Image-guided Therapy, Medical University of Vienna, Vienna, AUSTRIA, [3]Division of Nuclear Medicine, Department of Biomedical Imaging and Image-guided Therapy, Medical University of Vienna, Vienna, AUSTRIA.

Aim: Standard MR-based attenuation correction (AC) in PET/MRI is based on dedicated MR images and thus, not intrinsically representative of measured attenuation coefficients. This may lead to a bias in the reconstructed PET activity values. Here, we evaluate standardized uptake values (SUV) of reference regions in FDG-PET/MRI whole-body (WB) imaging in dual-time point examinations.Material and Methods: SUV of reference regions (LI: liver, MD: mediastinum and MU: muscle) were defined in two patient groups: single-injection, dual-scan (SI-DS) PET/CT-PET/MR or single-injection, single-scan (SI-SS) PET/MR examination.SI-DS group: WB-imaging of 77 patients was performed 77±28min pi of 250MBq FDG on a Siemens Biograph-TPTV and repeated 133±30min pi on a Biograph mMR PET/MR. Standard acquisition, AC and reconstruction protocols were used. For each patient volumes of interest (VOI) were defined manually on the PET/CT images for LI (14mL), MD (4.5mL) and MU (4.5mL). VOIs were transferred manually to co-registered PET/MR image data.SI-SS group: WB-imaging of 30 patients was performed 93±19min pi of 250MBq FDG on a Siemens Biograph mMR. Similar size VOIs were defined manually on AC-PET images for LI (14mL), MD (4.3mL) and MU (4.2mL). Mean and maximum SUV were calculated for all scans and regions. Paired and non-paired Willcoxon tests ($p<0.05$) were used to test differences in SUV for significance of PET/CT versus PET/MR in SI-DS and PET/MR in SI-DS versus SI-SS, respectively.Results: In SI-DS SUVmax in PET/CT and PET/MR was 4.1(±0.8) and 2.4(±0.7) for LI, 3.1(±0.7) and 1.9(±0.7) for MD and 1.6(±0.5) and 1.1(±0.5) for MU, respectively. Corresponding SUVmean values were: 2.6(±0.5) and 1.6(±0.4) for LI, 2.0(±0.4) and 1.2(±0.4) for MD and 0.9(±0.3) and 0.6(±0.3) for MU, respectively. Differences were statistically significant ($p<0.001$).In SI-SS SUVmax was 2.2(±0.4) for LI, 2.0(±0.5) for MD and 0.9(±0.3) for MU. Corresponding SUVmean values were: 1.6(±0.3), 1.4(±0.3) and 0.6(±0.1), respectively. Differences to the corresponding SUV in the PET/MR data SI-DS group were not statistically significant in the liver ($p>0.05$), but statistical significance was found in MD (SUVmean) and MU (SUVmax).Absolute SUV differences between PET/MR in SI-SS and SI-DS examinations were similar to pi-time-dependent differences reported in Cheng et al. (MIB 2013) and Laffon et al. (JNMT 2011). Absolute differences between PET/CT and PET/MR were larger, most likely due to differences in the AC methods.Conclusion: Group-wise comparison of PET/CT and PET/MR data indicates a systematic underestimation of SUVs in reference regions of PET/MR images following standard MR-AC compared to PET/CT.

OP417

Do Metal Objects in the Topogram Influence the Patient Dose?

K. Falch[1], C. Baun[1], S. Shanmuganathan[1], M. Nikolajsen[2], O. Gerke[1], P. Hoeilund-Carlsen[1]; [1]Odense University Hospital, Odense, DENMARK, [2]University College Lillebaelt, Odense, DENMARK.

Aim: Patients scheduled for PET/CT are always requested to remove metal objects if possible from their clothes and body before the scan. However, quite often the planning CT topogram reveals forgotten items such as dentures, jewelry, keys, or coins. If these objects are removed before the diagnostic CT scan without performing a new topogram, the dose modulation software miscalculates the mA, and the radiation dose to the patient will increase.The aim of this study was to assess the impact of metal objects in the topogram upon the radiation dose to the patient if a new topogram is not performed after removal of these high attenuation objects. Methods and materials: The study was performed using an Alderson phantom with a metal object present during the topogram in a diagnostic CT protocol. Three objects were used: a belt in the pelvic area, a key at the right thorax, and a cell phone at the right thigh. For each object, 10 scans were performed removing the object between the topogram and the CT scan, thus, a total of 30 'with-object-scans' were performed. The results of these were compared to 10 scans performed without any metal objects present during the topogram. The CT dose for each scan was estimated by the dose length product (DLP). An exploratory linear regression model was applied on the dose-length product (DLP) using the different circumstances as explanatory factor ('without object' (reference) vs. 'with belt' vs. 'with key' vs. 'with cellphone'). Results: *Preliminary results based on the first 20 scans*: Compared to scout without object, mean DLP was increased by 2.26 mGy-cm (95% CI: 1.68-2.84; $p<0.0001$) in phantoms with belt and decreased by 0.65 mGy-cm (95% CI: 0.07-1.23; $p=0.03$) in phantoms with key. With cellphone, DLP was increased by 1.26 mGy-cm, but not to a statistically significant degree (95% CI: 0.68-1.84)). Adjusted R squared was 0.87. Conclusion: These preliminary data show that the dose to the patient is increased when a larger metal object is present during the topogram and no new topogram is performed after removal prior to the diagnostic CT scan. This should encourage technologists to perform a new topogram, whenever changes of the scanning circumstances have been made.

OP418

The Effect of Type of Collimation, Duration of Image Acquisition and Scatter Correction in Heart-to-Mediastinum Ratio of I-123-MIBG Scintigraphy

S. Chaves, T. Vieira, A. Sá Pinto, V. Alves, A. Fernandes, J. G. Pereira; Centro Hospitalar de São João, Porto, PORTUGAL.

Aim: Heart-to-mediastinum ratio (H/M) has been commonly utilized as an indicator of myocardial 123I-Metaiodobenzylguanide (123I-MIBG) uptake.However, estimates of the H/M vary depending on the choice of acquisition parameters and the application of corrections to physical phenomena such as scattering.The purpose of this study was to analyze how the choice of different acquisition times, collimator types and scatter correction (SC) influences the H/M calculation.Materials and MethodsWe randomly selected 6 patients that were sent to our Nuclear Medicine Department for oncological evaluation. Images acquisition began 3 hours post-injection of 123I-MIBG (185-370 MBq). First, were acquired 2 sequential thoracic static (TS) images of 5 minutes (5M) each, (LEHR collimators; 256x256 matrix; 20% energy window was set on 159 keV); this step was repeated, in sequence, using ME collimators. After this, a whole body (WB) scanning (LEHR collimators; 256x1024 matrix; speed of 10 cm/min) was acquired. SC was applied defining a second window (130 keV +/- 10%) during the acquisition of TS and WB imaging, when using LEHR collimators. Ten minutes images (10M) were obtained by the sum of the counts in the sequential 5 minute images. An irregular ROI was manually drawn over the left ventricle (H) and a rectangular ROI (120 pixels) was placed in the upper mediastinum (M). The H/M was defined as the ratio of the average counts in the heart and mediastinum ROI's. H/M ratios were calculated for the eight images for each patient: 10M/LEHR, 10M/LEHR/SC, 5M/LEHR, 5M/LEHR/SC, 10M/ME, 5M/ME, WB, WB/SC. The correlations of the H/M ratios of the eight images were determined.Results and ConclusionMean H/M ratios for WB, 5M/LEHR, 10M/LEHR, 5M/ME, 10M/ME, WB/SC, 5M/LEHR/SC, 10M/LEHR/SC, were 1.75 ± 0.25, 1.82 ± 0.30, 1.82 ± 0.30, 2.43 ± 0.48, 2.46 ± 0.49, 3.24 ± 0.95 3.46 ± 0.97, 3.92 ± 1.24, respectively.There were no significant correlations of H/M ratios of SC images with non-SC images.There were significant correlations of H/M ratios obtained in images with 5M and 10M, for both type of collimators studied (rLEHR = 0.99, errorLEHR = 0,01 and rME = 0.98, errorME = 0,09), with 10M/LEHR and WB (rWB = 0.91, erroWB = 0,15), with 10M/LEHR and 10M/ME (r10M = 0.97, error10M = 0,09) and with 5M/LEHR and 5M/ME (r5M = 0.96, error5M= 0, 11).This research suggests that H/M ratios may be obtained from images with smaller acquisition times, across different types of collimators and administered activities.

An automatic delineation method for bone marrow absorbed dose estimations of 89Zr PET/CT studies

N. E. MAKRIS, R. Boellaard, C. W. Menke-van der Houven van Oordt, A. A. Lammertsma, M. C. Huisman; VU University Medical Center, Amsterdam, NETHERLANDS.

Purpose: To develop and validate an automatic delineation method for estimating red marrow (RM) activity concentrations and absorbed doses in positron emission tomography/computed tomography (PET/CT) studies using ^{89}Zr labelled tracers. Methods: Five patients with advanced colorectal cancer received 37.1 ± 0.9 MBq [^{89}Zr]cetuximab, 2 hours after administration of a therapeutic dose of 500 mg m^{-2} unlabelled cetuximab. For each patient, five PET/CT scans (1, 24, 48, 96 and 144 h post injection) were acquired using a Gemini TF-64 PET/CT scanner. Low dose CT data were used to manually generate volumes of interest (VOI) in the lumbar vertebrae (LV). In addition, LV VOI were generated automatically using an active contour method applied to the low dose CT. This method first identifies the outer bone structure of the LV, based on local intensity information in the low dose CT image, and subsequently partitions the LV between compact bone and bone marrow. RM activity was then determined by mapping the low dose CT derived RM VOI onto the corresponding PET scans. Finally, these activities were used to derive residence times and, subsequently, the self and total RM absorbed doses using OLINDA/EXM 1.1. Results: High correlations (r^2>0.85) between manual and automated VOI methods were obtained for both RM activity concentrations and total absorbed doses. On average, the automatic method provided values that were less than 5% lower than those obtained with the manual method. Conclusions: An automated and efficient VOI method, based on an active contour approach, was developed, enabling accurate estimates of RM activity concentrations and total absorbed doses.

Phase II Study of Lutetium-177-labeled Anti Carbonic Anhydrase IX Monoclonal Antibody Girentuximab in Patients with Advanced Renal Cell Carcinoma.

C. H. J. Muselaers[1], M. J. Boers-Sonderen[2], T. J. van Oostenbrugge[1], O. C. Boerman[3], I. M. E. Desar[2], A. B. Stillebroer[4], S. F. Mulder[2], C. M. L. van Herpen[2], J. F. Langenhuijsen[4], E. Oosterwijk[4], P. F. A. Mulders[4], W. J. G. Oyen[3]; [1]Radboudumc, Dept. of Urology, Dept. of Radiology and Nuclear Medicine, Nijmegen, NETHERLANDS, [2]Radboudumc, Dept. of Medical Oncology, Nijmegen, NETHERLANDS, [3]Radboudumc, Dept. of Radiology and Nuclear Medicine, Nijmegen, NETHERLANDS, [4]Radboudumc, Dept. of Urology, Nijmegen, NETHERLANDS.

Aim: Despite recent advances in treatment of metastatic clear cell renal cell carcinoma (ccRCC), the search for alternative treatment modalities which induce durable response with milder toxicity profiles continues. A phase II radioimmunotherapy (RIT) trial with ^{177}Lutetium (^{177}Lu)-girentuximab was initiated based on the encouraging results of a phase I to evaluate the efficacy of this RIT approach in patients with advanced ccRCC. Materials and methods: In this uncontrolled, non-randomized phase II trial, patients with progressive metastatic ccRCC who met the inclusion criteria received RIT with ^{177}Lu labeled girentuximab if targeting of the antibody was observed after a diagnostic injection with ^{111}Indium labeled girentuximab. Patients were eligible for another treatment cycle if no prolonged grade 4 hematological toxicity and at least stable disease (SD) according to RECIST v1.1 was observed on evaluation after 3 months. Retreatment was at 75% of the previous activity dose with a maximum of 3 treatment cycles. Results: Between August 2011 and April 2014, 14 patients enrolled in the study and received at least one infusion with ^{177}Lu-girentuximab. SD after the first RIT was observed in 8 patients (57%), partial regression (PR) was seen in 1 patient (7%), whereas progressive disease (PD) was seen in the other 5 (36%) patients. Of the 8 patients with SD and 1 with PR, 3 patients were not eligible for retreatment due to prolonged hematological toxicity. After the second treatment cycle, PD was observed in 1 out of 6 patients. The treatment was generally well tolerated, but resulted in transient grade 3-4 hematological toxicity in all but 1 patient. Conclusion: RIT with ^{177}Lu-girentuximab resulted in disease stabilization in the majority of patients with progressive ccRCC. Apart from transient myelotoxicity, RIT was well tolerated.

OP421

Preliminary experience in treating high-risk neuroblastoma using tandem high dose dosimetry-guided 131I-MIBG treatment combined with chemotherapy

G. Boni[1], s. mazzarri[1], M. Menconi[2], A. C. Traino[3], E. Borsò[4], S. Bernasconi[2], G. Casazza[2], C. Favre[5], D. Volterrani[1]; [1]Regional Center Of Nuclear Medicine, University Hospital Of Pisa, pisa, ITALY, [2]Division of Pediatric Onco-hematology, University Hospital, Pisa, Italy, pisa, ITALY, [3]Health Physics Unit, Section of Medical Physics, University Hospital, Pisa, Italy, pisa, ITALY, [4]Nuclear Medicine Division, Sant'Andrea Hospital of La Spezia, La Spezia, ITALY, [5]Division of Pediatric Onco-hematology, Meyer Pediatric Hospital, Florance, Florance, ITALY.

Aim: To evaluate the feasibily and safety data of tandem high dose dosimetry-guided 131I-MIBG infusions combined with chemotherapy in patients with refractory neuroblastoma. Method: Patients (age 8.5±4.4 yrs) with high-risk neuroblastoma refractory to multiple chemotherapy schedules and evidence of MIBG-avid disease by 123I-MIBG scan received two "tandem" high-dose 131I-MIBG treatments within 15 day. During the first infusion of 131I- MIBG, the patients received 12 mCi/Kg (mean 259 mCi, range 230-320 mCi). A contemporary dosimetric study was performed to calculate the absorbed dose by patient to estimate the

activity require for the second 131I-MIBG treatment (the target is to deliver a combined whole body radiation dose of 4 Gy). During day 1-5 by the first administration, patients received Topotecan iv 0.7 mg/m2 daily as cytotoxic drug and also as radiosensitiser. After 15 days patients were retreated with 131I-MIBG, and between Day 15-19 Topotecan 0.7 mg/m2 daily was administered again. Peripheral blood stem cells (PBSC) were available for transplantation in all the patients.Post-treatment evaluations were performed every 6-8 weeks after the infusion, including a diagnostic 123I-MIBG scan, tumor imaging studies (CT or MRI) as well as urine catecholamines, and a bone marrow aspirate and biopsy.ResultsFour patients with evidence of MIBG-avid disease were treated from December 2013 to date.All the patients completed the protocol receving a second infusion of 131I-MIBG (mean activity 283 mCi, range 100-353 mCi) to deliver a total whole body absorbed dose of 4 Gy The median time to second infusion was 16 days (range 14-19 days). No important adverse events were observed during both combined treatments. Expected bone marrow toxicity reached grade 4 neutropenia in 3 patients, grade 3 thrombocytopenia in 2 patients - which were treated with platelet transfusions - and grade 1 anemia in 2 patients. Bone marrow suppression completely recovered two months after second cycle in all the patients, without requiring PBSC transplantation. We observed a response rate (CR+PR) in 2/4 patients 3 months after the completion of the combined therapeutic regimen. Regarding other two patients, one case of stability and one of progression disease occurred. Conclusion. Single-centre preliminary experience show the feasibility of radiometabolic therapy with tandem high-dose dosimetry-guided of 131I-MIBG combined with chemotherapy. This therapy seems to be a safe and effective treatment modality for high-risk neuroblastoma with compromised organ functions. However, this was a small and heterogeneous cohort and further studies are needed.

OP422

Compared therapeutic efficacy of 177Lu-HH1 and 177Lu-rituximab in non-Hodgkin B-cell lymphoma

A. Pichard, **Jr**.[1,2,3], S. Marcatili[4,5], A. Courteau[4,5], R. Ladjohounlou[1,2,3], G. Cartron[6], I. Navarro-Teulon[1,2,3], A. Repetto-Llamazares[7], H. Heyerdahl[7], M. Bardiès[4,5], J. Dahle[7], J. Pouget[1,2,3]; [1]Inserm U1194, Montpellier, FRANCE, [2]IRCM, Institut de Recherche en Cancérologie de Montpellier, Montpellier, FRANCE, [3]Université de Montpellier, Montpellier, FRANCE, [4]UMR 1037 INSERM, Toulouse, FRANCE, [5]Centre de Recherche en Cancérologie de Toulouse, Toulouse, FRANCE, [6]6Département d'Hématologie, Unités Mixtes de Recherche–Centre National de la Recherche Scientifique 5235, Centre Hospitalier Universitaire de Montpellier, Montpellier, FRANCE, [7]Nordic Nanovector ASA, Kjelsåsveien 168 B, Oslo, NORWAY.

Aims. We compared in vitro and in vivo the therapeutic efficacy of a new antibody radionuclide conjugate (ARC), namely Betalutin™ and of 177Lu-labeled rituximab. Betalutin™ consists of the HH1 monoclonal antibody (mAb) radiolabeled with 177Lu and is directed against the CD37 receptor expressed by B-lymphoma cells. Materials and methods. In vitro, the therapeutic efficacy of 177Lu-rituximab, Betalutin™ and of the non-specific 177Lu-cetuximab was assessed in three different lymphoma cell lines (Ramos, DOHH2 and Rec-1) exposed for 18 hours to increasing activities (0, 0.5, 1, 2, 4 and 6 MBq/mL) of radiolabeled mAbs or to unlabelled mAbs (0-40μg/mL). Clonogenic survival was then measured and the mean absorbed dose to the nucleus was calculated using the MIRD formalism. Therapeutic efficacy and toxicities were also determined in mice subcutaneously xenografted with Ramos cells after intravenous administration of the three ARCs. SPECT-CT imaging and conventional biodistribution studies were performed and used for further tumour and organ absorbed dose assessment. Results. The highest cytotoxicity was observed for 177Lu-rituximab, followed by 177Lu-HH1 and the lowest for 177Lu-cetuximab. The highest sensitivity to ARC was observed in human follicular lymphoma cells (DOHH2) and the lowest for Burkitt lymphoma cells (Ramos), with mantel cell lymphoma cells (Rec-1) in between. Unlabelled rituximab was more efficient in killing cells than HH1 mAb mainly through apoptosis induction. The efficacies of the unlabelled mAbs were subtracted from the therapeutic efficacies of the ARCs to find the efficacies of the radiation only. In DOHH2, 177Lu-HH1 was more toxic per Gy than 177Lu-rituximab, 177Lu-cetuximab being in between. No linear nor linear-quadratic model fitted the data. The interpretation for Ramos survival curves was less obvious and depended on the chosen regression model: no differences in therapeutic efficacy of 177Lu-rituximab, 177Lu-HH1 and 177Lu-cetuximab were observed after linear-quadratic fitting (dose-effect relationship) while significant differences were observed when linear models were used (no dose-effect relationship). A linear relationship could be established between survival and the mean nucleus absorbed dose in both DOHH2 and Ramos cells exposed to 177Lu-cetuximab. In vivo, SPECT-CT study confirmed specific tumor targeting of Betalutin™. Preliminary results highlight the therapeutic efficacy of BetalutinTM associated with a lower toxicity than for 177Lu-rituximab. Conclusion. Our results show that the nature of absorbed dose-effect relationship associated with RIT of lymphoma depend on the nature of both ARC and cell line. Lack of absorbed dose-effect relationship may be explained by uncertainties inherent to absorbed dose assessment or to bystander effects.

OP423

Efficacy of radioembolization with holmium-166 microspheres; primary outcome of the phase II HEPAR trial

J. Prince, B. A. Zonnenberg, J. F. W. Nijsen, M. L. J. Smits, A. F. van den Hoven, F. J. Wessels, R. C. G. Bruijnen, M. N. G. J. Braat, G. C. Krijger, M. G. E. H. Lam, M. A. A. J. van den Bosch; UMC Utrecht, Utrecht, NETHERLANDS.

Aim: Microspheres containing holmium-166 in a poly L-lactic acid matrix (^{166}Ho) have been developed for radioembolization. In a phase 1 dose-escalation study, the maximum tolerated dose to the liver was found to be 60 Gy. The aim of this phase II trial was to evaluate the efficacy in patients with liver metastases. Materials and Methods: Patients were included in this single-center, single-arm study if they had liver-dominant metastases on baseline ^{18}F-FDG-PET with triphasic liver CT which were irresectable and refractory to systemic therapy. Patients received whole liver treatment (aimed absorbed dose 60 Gy, equal to 3.8 GBq/kg liver tissue). The study had a sequential design with an interim analysis after 30 patients, and every 6 patients, until a maximum of 48 patients. The primary objective was tumor response of two pre-specified target lesions on triphasic liver CT at 3 months, per RECIST 1.1. The response was calculated using evaluable patients (available case analysis) and with missing data imputed as progressive disease (imputed case analysis). Toxicity was scored using CTCAE version 4.03. Follow up continued until disease progression, or up to 12 months. Results: From May 2012 until March 2015, 56 patients with various primary tumors were included of whom 38 patients were treated. Four patients' outcomes were not evaluable due to: no response consensus among 3 raters, no contrast enhanced CT for evaluation, use of concomitant chemotherapy and death prior to imaging due to extrahepatic disease recurrence. Four others have not reached 3 months follow up. Stable disease or partial response in the liver after 3 months was detected in 20/30 patients (67%, 95% CI 49 – 81%) for the available case analysis and 20/34 (59%, 95% CI 42 – 74%) for the imputed case analysis; both proportions were above the pre-specified stopping boundary for treatment effect (40%), so the inclusion was closed. Median survival was estimated at 14 months (95% CI 8 – ∞ months). Clinical toxicity of grade 3 or 4 at any time after treatment consisted of: abdominal pain (18% of patients), nausea (9%), liver abscesses (3%), paroxysmal atrial tachycardia (3%), vomiting (3%), ascites (3%), gastric stenosis (3%), thoracic pain (3%), and upper gastrointestinal hemorrhage (3%). Laboratory examination after treatment showed grade 3 or 4 toxicities in levels of alkaline phosphatase (70%), gamma-GT (78%), lymphocytes (11%), and ALAT (4%).ConclusionRadioembolization with holmium-166 microspheres induces a tumor response in the liver with an acceptable toxicity profile.

OP424

Prolonged overall survival after 99mTc-MAA SPECT personalized treatment planning in radioembolization of hepatocarcinoma with 90Y glass microspheres: preliminary results of a 2 cohort study.

M. Maccauro[1], C. Chiesa[1], A. Facciorusso[2], M. Mira[3], C. Spreafico[4], R. Romito[1], C. Morosi[4], C. Sposito[2], S. Bhoori[2], M. Migliorisi[5], B. Padovano[1], E. Seregni[1], A. Marchiano'[4], F. Crippa[1], V. Mazzaferro[2]; [1]Nuclear Medicine, Foundation IRCCS Istituto Nazionale Tumori, Milan, ITALY, [2]Surgery 1, Foundation IRCCS Istituto Nazionale Tumori, Milan, ITALY, [3]Post graduate Health Physics School, University of Milan, Italy, Milan, ITALY, [4]Radiology 2, Foundation IRCCS Istituto Nazionale Tumori, Milan, ITALY, [5]Clinical engineering, Foundation IRCCS Istituto Nazionale Tumori, Milan, ITALY.

Aim: to estimate the clinical impact of 99mTc-MAA SPECT based personalized treatment planning in radioembolization (TARE) of hepatocarcinoma (HCC) with 90Y glass microspheres. Methods: 2 cohorts of intermediate/advanced HCC patients were treated. The cohort 1 of 52 patients was enrolled in a phase II prospective study (Mazzaferro 2013) with strict exclusion criteria: tumor burden > 50%, anti-tumor therapy including drug treatment within 30 days before TARE, previous TACE. Complete occlusion of the main trunk of portal vein affected few patients (4/29=14% PVT III, 1/29=3% PVT IV). Therapeutic activity was chosen according to the device pamphlet in order to deliver 120 Gy to the injected lobe. In Child A patients, a threshold for liver decompensation risk of 15% had been determined at 75 Gy (absorbed dose averaged on the whole parenchyma) with retrospective 99mTc-MAA SPECT dosimetry. For a tumor control probability of 50%, threshold was at 250 Gy for small lesions (10 gram) for larger lesions.189 sequential "real life" patients were enrolled in cohort 2, including any tumor mass, concomitant sorafenib, previous TACE and complete PVT. For a meaningful comparison, a subcohort of cohort 2 was selected applying retrospectively the exclusion criteria of cohort 1. The 90Y activity was personalized with prospective 99mTc-MAA SPECT dosimetric treatment planning and the previous thresholds. Liver decompensation within 6 months clearly attributable to progression was not attributed to the treatment. Results: treatment planning modified the activity in 73% of patients with respect to pamphlet indications. Activity was increased/decreased in 47%/25% of patients (mean +100%/-30%). The prescription coincided with the

device indication only in 28% of cases. The parenchyma absorbed dose standard deviation was strongly reduced in cohort 2 (30 Gy vs 16.5 Gy). Tumor absorbed doses did not differ. Treatment related liver decompensation incidence in Child A patients of subcohort 2 (11/71=15.5%) was maintained as in cohort 1 (6/43=14%), as programmed. Overall survival was prolonged: 15 m, 95% C.I [12 - 18] of cohort 1 versus 17 m, 95% C.I [13 - 19] in subcohort 2. The same is confirmed in the advanced patients with PVT: 13 m, 95% C.I. [9 - 17] versus 15 m, 95% C.I. [10 - 17]. Conclusion: in HCC patients without complete obstruction of portal vein, treatment planning resulted in fully personalized administrations, more homogeneous treatment conditions, identical toxicity incidence and prolonged survival with respect to the fixed dose of 120 Gy to lobe.

One-step radiosynthesis of 68Ga-DKFZ-PSMA at room temperature

Z. Wimana, C. Artigas, P. Flamen, G. Ghanem; Institut Jules Bordet, Université Libre de Bruxelles, Brussel, BELGIUM.

Germanium-68/Gallium-68 generator (68Ge/68Ga) has been under investigation and constant improvement since the late 1970s to reach GMP and pharmaceutical grades lately. Up-to-now, transchelation of 68Ga-cation at high temperatures has been the method of choice to prepare many tracers; however, more straight-forward radiosyntheses preferably at room temperature are now being developed as interesting alternatives to avoid the use of expensive equipment and lengthy procedures. This could allow a significant reduction in production cost and increase in the accessibility of Pet-based-molecular-imaging. We present here a one-step-labelling procedure of DKFZ-PSMA-11 ligand with 68Ga3+ at room temperature as a ready-to-use all-in-one kit and its successful use in prostate cancer patients.MATERIALS AND METHODS: A ready-to-use GMP kit (ANMI SA, Belgium) consisting in one vial containing lyophilized DKFZ-PSMA-11 (25μg), acetate buffer and excipients received up to 10ml of 0.1M HCL 68Ge/68Ga generator eluate directly and was allowed to incubate for 8-10 min at room temperature without any stirring. Radio-HPLC was used to compare radiochemical purity (RCP) as well as the stability of the tracer before and after SPE-C18 column purification. The same parameters were compared with preparations made with an automatic synthesizer with cassettes using Ga3+ purification/concentration on an ion exchanger, labeling at 95°C and C18 purification. RESULTS: The one-step method to prepare 68Ga-DKFZ-PSMA proved to be both highly efficient and reproducible. For the one step method we observed a labeling yield of 97.6±2.2%, a RCP of 99.7±0.3% and specific activity of 1.4±0.2 mCi/μg. In comparison, the tracer produced with the automated method showed similar RCP (>99.5%), specific activity (1.6±0.3 mCi/μg), but an important lower labeling yield (77.8±5.8%). The tracer produced with the one step method was stable in saline and serum over a course of 3h with a chemical purity above 99%. Purification over a SPE-C18 column did not result into substantial differences in RCP (99.9±0.1%) and stability (RCP at 3h>99%). No bacteriological burden or endotoxins were demonstrated. The C18-purified filter-sterilized end-product was administered to patients. CONCLUSION: We report here an original procedure to prepare 68Ga-DKFZ-PSMA and its successful use in metastatic prostate cancer patients for the first time.68Ga-DKFZ-PSMA is an example as the same procedure may be adaptable for other chelating groups and may considerably extend the variety of tracers by avoiding heat. With the introduction of pharmaceutical grade 68Ge/68Ga generators, would such methods mimic the success story of 99mTechnetium chemistry five decades ago is an open question.

OP426

Radiosyntheses and Preclinical Evaluation of Radiofluorinated PSMA-Ligands

J. Cardinale, M. Schäfer, M. Benesova, U. Bauder-Wüst, D. Komljenovic, M. Eder, M. E. Ladd, K. Kopka; German Cancer Research Center, Heidelberg, GERMANY.

Aim: Urea-based inhibitors of the prostate-specific membrane antigen (PSMA) are well known and promising candidates for the diagnosis (1,2) and therapy of prostate cancer. The aim of the project was the development of fine-tuned F-18 labelled PSMA-ligands affording an alternative ligand for the well-known 68Ga-PSMA-617 and 68Ga-PSMA-HBED-CC (68Ga-PSMA-11). Therefore the binding affinity and internalization characteristics have been determined for the selection of candidates for further in vivo biodistribution and PET experiments. Materials and Methods: The PSMA binding-motif Glu-NH-CO-NH-Lys was synthesized by a well-known method (3) on a solid phase (chlorotrityl-resin) and subsequently an amino acid linker was build up by fmoc-based solid phase peptide synthesis (SPPS). After separation from the resin and deprotection the peptidomimetics were conjugated using radiofluorinated prosthetic groups. The non-radioactive reference compounds were also prepared by SPPS. The Ki-values of all compounds were determined by competitive binding assays on LNCaP cells against 68Ga-PSMA-10 using the respective cold reference compounds. Subsequently the internalization of the radiofluorinated ligands was determined.

Moreover, two of the novel radiotracers were evaluated by dynamic PET experiments. Results: The no-carrier-added radiofluorination of the new PSMA-ligands with selected prosthetic groups was accomplished with good radiochemical yields. The Ki-values of the most promising compounds PSMA-1001, PSMA-1002 and PSMA-1003 were in the range of 1.5-3.0 nM. The internalized activity per 10e5 cells was approx. 3 % for PSMA-1001/1002 and approx. 7 % for PSMA-1003, respectively. During dynamic PET PSMA-positive LNCaP tumors could be visualized using radiofluorinated PSMA-1001 and PSMA-1003 as early as 1 h p.i.. However, both tracers showed significant uptake in the liver. Altogether PSMA-1003 led to the best results and the structure is currently modified for further optimization of the pharmacokinetics. Conclusions: The preparation of the precursors by SPPS enables the build-up of a huge library of diverse PSMA-targeted ligands. Based on PSMA-617, a series of promising radiofluorinated PSMA ligands was developed and evaluated in vitro and in vivo. After a further improvement of the pharmacokinetics the novel 18F-labelled tracers may lend themselves as promising compounds for first-in-man clinical studies. Literature: (1) A. OP427

NODA-GA-PSMA : A versatile probe for SPECT/PET imaging of PSMA-positive tumors.

E. Gourni[1,2,3], V. Goncalves[4], F. Denat[4], P. T. Meyer[2], H. R. Maecke[2]; [1]German Cancer Consortium (DKTK), Heidelberg, GERMANY, [2]Department of Nuclear Medicine, University Hospital Freiburg, Freiburg, GERMANY, [3]German Cancer Research Center (DKFZ), Heidelberg, GERMANY, [4]Institut de Chimie Moléculaire de l'Université de Bourgogne, Dijon, FRANCE.

Objectives: The type II integral membrane protein, prostate specific membrane antigen (PSMA), is overexpressed on prostate cancer as the stage and grade of the tumor progresses, especially in androgen-independent, advanced and metastatic disease. The ability to image PSMA by using ^{68}Ga-HBED-CC-PSMA was proven to be successful preclinically and clinically. The present study aims at developing and evaluating an urea-based PSMA inhibitor suitable for labeling with ^{111}In for SPECT as well as ^{68}Ga and ^{64}Cu for PET imaging. Methods: The urea-based PSMA inhibitor - lysine-urea-glutamate - coupled to the spacer Phe-Phe-D-Lys(suberoyl) and functionalized with the chelator 1,4,7-triazacyclononane, 1-glutaric acid-4,7 acetic acid (NODAGA), to obtain NODAGA-Phe-Phe-D-Lys(suberoyl)-Lys-urea-Glu (VG66). VG66 was radiolabeled with ^{111}In, ^{68}Ga and ^{64}Cu. The radioconjugates were further evaluated in vitro and in vivo in LNCaP xenografts by biodistribution and PET studies. Biodistribution studies were also performed with ^{68}Ga-HBED-CC-PSMA and ^{111}In-DKFZ-PSMA-617 for comparison. Results: ^{68}Ga-VG66, ^{64}Cu-VG66 and ^{111}In-VG66 were prepared in radiochemical purity >95% and specific activities 85, 30 and 10 MBq/nmol exhibiting a $\log D_{octanol/PBS}$ of -3.54±0.06, -3.33 ±0.09 and -3.32±0.05, respectively. $^{68/nat}$Ga-VG66, $^{64/nat}$Cu-VG66 and $^{111/nat}$In-VG66 exhibited high affinity for the LNCaP cells, with K_d values of 19.3±2.5 nM, 25.1±2.0 and 5.5±0.9 nM, respectively. They revealed comparable internalization profiles with approximately 75% of the total cell associated activity internalized after 3h of incubation with the cells. ^{68}Ga-VG66 showed very high stability after its administration in mice and metabolite analysis of the mouse-plasma 15 min p.i.. Tumor uptake of ^{68}Ga-VG66 (14.5±2.9% IA/g) in LNCaP xenografts at 1 h p.i is slightly lower than ^{68}Ga-HBED-CC-PSMA (15.8±1.4% IA/g) but statistically not significant (P=0.67). The tumor-to-normal tissue ratios at 1 and 2 h p.i of ^{68}Ga-VG66 are comparable to ^{68}Ga-HBED-CC-PSMA (P>0.05). Tumor uptake of ^{111}In-VG66 (28.5±2.6% IA/g) at 1 h p.i. is lower than ^{111}In-DKFZ-PSMA-617 (52.1±6.5% IA/g) (P=0.02). The tumor-to-normal tissue ratios of ^{111}In-DKFZ-PSMA-617 are significantly higher than ^{111}In-VG66 at all tested time points. Tumor uptake of ^{64}Cu-VG66 at 1 h p.i was 20.3±1.5% IA/g. Biodistribution studies at later time points showed increasing tumor-to-background ratios with time. This was also illustrated by the PET images. Conclusion: VG66 can efficiently be labeled with ^{68}Ga, ^{64}Cu and ^{111}In leading to radiotracers with high affinity towards PSMA. ^{68}Ga-VG66 is comparable to HBED-CC-PSMA in terms of tumor uptake (P=67) and tumor to normal tissue ratios (P>0.05) Their promising in vivo pharmacokinetic performance may contribute to the improvement of the diagnostic imaging of tumors overexpressing PSMA.

68Ga-PSMA11-PET/CT - a new technique with high potential for the radiotherapeutic management of prostate cancer patients

F. Giesel[1], H. Fiedler[1], M. Stefanova[1], C. Kratochwil[1], A. Afshar-Oromieh[1], K. Kopka[2], J. Debus[3], U. Haberkorn[1], F. Sterzing[3]; [1]Radiologische Klinik / Abt. für Nuklearmedizin, Heidelberg, GERMANY, [2]Deutsches Krebsforschungszentrum (DKFZ) / Abteilung für Radiopharmazeutische Chemie, Heidelberg, GERMANY, [3]Radiologische Klinik / Abt. für Strahlentherapie, Heidelberg, GERMANY.

AIM: Radiotherapy is the main therapeutic approach besides

surgery of localized prostate cancer. It relies on risk stratification and exact staging. This report analyses the potential of [68Ga]Glu-urea-Lys(Ahx)-HBED-CC (68Ga-PSMA11) a new PET-tracer targeting PSMA for prostate cancer staging and individualized radiotherapy planning. MATERIALS & METHODS: A cohort of 57 patients with prostate cancer scanned with 68Ga-PSMA11 PET-CT for radiotherapy planning was retrospectively reviewed. 15 patients were at initial diagnosis and 42 patients at time of biochemical recurrence. Staging results of conventional imaging, including bone scintigraphy, CT or MRI, were compared with 68Ga-PSMA Ligand PET-CT results and the influence for radiotherapeutic management was quantified. RESULTS: 68Ga-PSMA ligandPET-CT has had a dramatic impact on radiotherapy application in the presented cohort. In 50.8% of the cases therapy was changed. CONCLUSION: The presented Imaging technique of 68Ga-PSMA-PET-CT could be a key technology for individualized radiotherapy management in prostate cancer.

The novel theranostic PSMA-ligand PSMA-617 in the diagnosis of prostate cancer by PET/CT: biodistribution in humans, radiation dosimetry and first evaluation of tumor lesions

A. Afshar-Oromieh[1], H. Hetzheim[2], C. Kratochwil[1], M. Benesova[3], M. Eder[4], O. Neels[4], W. Kübler[5], F. L. Giesel[1], W. Mier[6], K. Kopka[4], U. Haberkorn[1]; [1]University Hospital of Heidelberg, Heidelberg, GERMANY, [2]Div. of Medical Physics in Radiology, German Cancer Research Center, Heidelberg, Germany, Heidelberg, GERMANY, [3]Div. of Radiopharmaceutical Chemistry, German Cancer Research Center, Heidelberg, GERMANY, [4]Div. of Radiopharmaceutical Chemistry, German Cancer Research Center, Heidelberg, Heidelberg, GERMANY, [5]Div. of Radiation Protection and Dosimetry, German Cancer Research Center, Heidelberg, Heidelberg, GERMANY, [6]Division of Radiochemistry, University Hospital of Heidelberg, Heidelberg, GERMANY.

Purpose: PET-imaging with the ligand of the prostate-specific membrane antigen 68Ga-PSMA-11 is regarded as a significant step forward in the diagnosis of prostate cancer (PCa). More recently, a PSMA-ligand was developed which can be labeled with 68Ga, 177Lu and 90Y. This ligand, named PSMA-617, therefore enables both, diagnosis and therapy of PCa. The aim of this evaluation was to investigate the distribution of PSMA-617 in normal tissues and in PCa lesions as well as the radiation exposure of PET-imaging with 68Ga-PSMA-617. Methods: Nineteen patients with recurrent PCa were referred to 68Ga-PSMA-617-PET/CT. Quantitative assessment of tracer uptake of several organs and 53 representative tumor lesions was performed in 15 patients 1h and 3h p.i. In four additional patients, the same procedure was conducted at 5min, 1h, 2h, 3h, 4h and 5h p.i. Based on the data of these four patients the radiation exposure of a 68Ga-PSMA-617-PET/CT was identified. Results: Intense tracer uptake was observed in kidneys and salivary glands. In 14 of 19 patients (73.7%) at least one tumor suspicious lesion was detected 3h p.i.. Of 53 representative tumor lesions selected at 3h p.i., 47 lesions were visible at 1h p.i. Mean tumor-to-background ratios for SUVmax were 20.4 ± 17.3 (2.3 - 84.0) at 1h p.i. and 38.2 ± 38.6 (3.6 - 154.3) at 3h p.i. Average radiation exposure (effective dose) is approximately 2.1E-2 mSv/MBq. Conclusion: Within healthy organs, kidneys and salivary glands demonstrated the highest 68Ga-PSMA-617 uptake. The radiation exposure is relatively low. 68Ga-PSMA-617 can show PCa-lesions with very high contrast. Images conducted at 3h p.i. detected more PCa-lesions compared to images at 1h p.i..

OP430

Value of Ga-68 PSMA PET/CT for Patient Selection and Follow-up of Metastasized Prostate Cancer Patients Undergoing Peptide Radioligand Therapy (PRLT) with Lu-177 DOTAGA-PSMA Inhibitor

H. R. Kulkarni[1], H. J. Wester[2], A. Singh[1], R. P. Baum[1]; [1]THERANOSTICS Center for Molecular Radiotherapy and Molecular Imaging, Bad Berka, GERMANY, [2]Pharmaceutical Radiochemistry, Technical University Munich, Munich, GERMANY.

Aim: Ga-68 PSMA-HBED-CC (Ga-68 PSMA) is a sensitive and specific PET tracer for the detection of prostate cancer recurrences and metastases. The aim of this study was to determine the role of Ga-68 PSMA PET/CT in patients with metastasized castrate resistant prostate cancer (mCRPC) undergoing peptide radioligand therapy (PRLT) using Lu-177 DOTAGA-PSMA inhibitor (Lu-177 PSMA). Methods: Ga-68 PSMA PET/CT (contrast-enhanced CT scan) was performed in 217 patients (mean Gleason score 7±1, mean age 63±11 years, median PSA 58.2, range 0.1-2223 ng/ml), and repeated in 31 patients for follow-up after 2-4 cycles of PRLT using Lu-177 PSMA. PET/CT findings were also correlated with post-therapy Lu-177 PSMA whole body scans and SPECT/CT studies performed during therapy. Retrospective analysis was performed using our prospective database of patients undergoing PRLT. Results: Metastatic disease with PSMA expression was noted in 40 patients, including bone (n=35), two or more lymph node sites (n=31), lung (n=5) and liver (n=5). All Lu-177 PSMA positive lesions (noted on post-therapeutic scans) were previously also identified on PET/CT. Molecular response to PRLT could be assessed after 2-4 cycles of PRLT by Ga-68 PSMA PET/CT in 31 patients. Molecular response (EORTC) was noted in 14 patients, demonstrating strong correlation

between change in SUVmax and change in serum PSA level (r=0.84). On the other hand, morphological criteria (RECIST) established objective response in 6 of 14 patients. Disease remained stable in 7 and 15 patients, according to EORTC and PERCIST, respectively, and progressed in 10 patients. Conclusions: Ga-68 PSMA PET/CT enables not only effective selection of metastasized prostate cancer patients for therapy with Lu-177 labeled DOTAGA-PSMA inhibitor, but also for the assessment of objective therapy response, correlating well with change in serum PSA. It may be useful for the early identification of responders and non-responders, since molecular response precedes morphological changes in tumors.

FDG PET Imaging of a Rat Model of Autoimmune Myocarditis: Comparison with Histological Analysis

R. A. Werner[1,2], Y. Maya[1,3], V. Jahns[4], H. Wakabayashi[1], M. Nakajo[1], K. Fukushima[5], M. Javadi[6], T. Yanagisawa[7], R. Jahns[8], T. Higuchi[1,2]; [1]Department of Nuclear Medicine, Universitätsklinikum Würzburg, Würzburg, GERMANY, [2]Comprehensive Heart Failure Center, Würzburg, GERMANY, [3]Research Centre, Nihon Medi-Physics Co., Ltd., Chiba, JAPAN, [4]Department of Pharmacology, Universitätsklinikum Würzburg, Würzburg, GERMANY, [5]Hyogo College of Medicine, Hyogo, JAPAN, [6]Division of Nuclear Medicine, Johns Hopkins University, MD, UNITED STATES, [7]Department of Cardio-angiology, Kitazato University School of Medicine, Tokyo, JAPAN, [8]Department of Internal Medicine I, University of Würzburg, Würzburg, GERMANY.

Aim: Reliable non-invasive tools to diagnose inflammatory activity are clinically relevant in patients with myocarditis for optimization of therapeutic strategies. The aim of this study is to assess the feasibility of serial monitoring of the inflammatory activity in a rat model of acute myocarditis utilizing high resolution small animal PET system and F-18 fluorodeoxyglucose (FDG). Materials and Methods: Autoimmune myocarditis was induced in Lewis rats by immunizing twice at a week interval with 10mg/mL porcine cardiac myosin with Freund's complete adjuvant (n=12) or adjuvant alone as control (n=8). Rats received serial imaging at week 1, 2 and 3 after first immunization utilizing a micro PET system. At fasting condition (>12h), static 10min chest FDG PET scans were started 60min after tracer administration. F-18 fluorobenzyl triphenyl phosphonium (FBnTP) myocardial perfusion PET imaging was also performed to identify the localization of the FDG signal in subset of animals. For post-mortem ex-vivo analysis (week 3), the hearts were sliced into 20-μm short axis sections for autoradiography and histological analysis with HE staining. Region of interest (ROI) were set on the autoradiograms, and the uptake values of each ROI were calculated as the background-corrected quantum levels per unit area (QL/pixel). Results: Multiple focal cardiac inflammatory lesions with intense macrophage infiltration were histologically identified at week 3 after immunization in 10 of 12 animals and 0 of 8 adjuvant alone controls. FDG PET showed multiple high-contrast focal tracer accumulation in all histologically confirmed myocarditis hearts at week 3, while no focal accumulation in controls (%ID/cc: 1.62±0.93 vs 0.25 ±0.04, $p<0.05$). Serial FDG PET imaging provided time course of the uptake signals (%ID/cc: 0.25±0.10, 0.28±0.11, 1.62±0.93, $p<0.05$ at week 1, 2 and 3, respectively). Ex-vivo analysis confirmed co-localization of the area of FDG accumulation and inflammatory lesions. Mean FDG activity (QL/pixel) at the inflammatory lesions identified by histology (223±99) was significant higher than remote control area (53±30, $p<0.0001$) and control hearts (13±4, $p<0.0001$). Conclusion: Focal increased FDG PET signals in the heart was well correlated with histologically identified inflammatory lesions in a rat model of autoimmune myocarditis. This FDG-PET imaging might be a promising approach for serial monitoring of the inflammatory activity, and this experimental platform would be available for better understanding of the inflammation dynamics for the development of novel therapeutic strategies.

OP432

Assessment of radiolabeled methionine for imaging myocardial inflammation in a rat model of autoimmune myocarditis: Comparison with18F-FDG and histological findings

Y. Maya[1,2], R. A. Werner[1,3], V. Jahns[4], H. Wakabayashi[1], M. Nakajo[1], K. Fukushima[5], T. Yanagisawa[6], R. Jahns[7], T. Higuchi[1,3]; [1]Department of Nuclear Medicine, Universitätsklinikum Würzburg, Würzburg, GERMANY, [2]Research Centre, Nihon Medi-Physics Co., Ltd., Chiba, JAPAN, [3]Comprehensive Heart Failure Center, Würzburg, GERMANY, [4]Department of Pharmacology, Universitätsklinikum Würzburg, Würzburg, GERMANY, [5]Hyogo College of Medicine, Hyogo, JAPAN, [6]Department of Cardio-angiology, Kitazato University School of Medicine, Kanagawa, JAPAN, [7]Department of Internal Medicine I, University of Würzburg, Würzburg, GERMANY.

Objectives: Myocarditis is thought to be one of the major causes of heart failure and sudden cardiac death in young adults. Currently, the definitive non-invasive method to detect and monitor the cardiac inflammatory lesions is missing, and invasive endomyocardial biopsy is associated with inherent sampling error. In this study, we

investigated the potential of radiolabeled methionine to assess the inflammatory activity utilizing a rat model of autoimmune myocarditis. Methods: Autoimmune myocarditis was induced in Lewis rats (150-210g) by immunizing twice at a 7-day interval with 10-mg/mL porcine cardiac myosin with Freund's complete adjuvant (mycobacterium tuberculosis) (n=4) or adjuvant alone as controls (n=4). On day 21 after immunization, study was performed with dual-tracer autoradiography to assess distribution of 14C-methionine and 18F-FDG in the hearts. At fasting condition (>12h), both 18F-FDG (37MBq) and 14C-methionine (0.5MBq) were administrated 90 min and 20 min before euthanizing the rats, respectively. The hearts were removed, frozen, and sliced into 20-μm short axis sections for autoradiography and histological analysis with HE staining. Region of interests (ROI) were set on the autoradiograms, and calculated the uptake values of each ROI, as the background-corrected quantum levels per unit area (QL/pixel) for 14C-methionine and 18F-FDG. Results: Multiple focal cardiac inflammatory lesions were histologically identified in all hearts with myosin treatment group, while no lesions were seen in rats with adjuvant alone. The autoradiographic images clearly demonstrated high-density accumulation of 14C-methionine, corresponding to histologically confirmed inflammatory lesions and focal 18F-FDG accumulation. The 14C-methionine uptake (mean binding signal intensity, QL/pixel) in the inflammatory lesions was significantly higher than remote non-inflammatory area (2561 ± 894 vs 1068 ± 339, $p<0.0001$) and control hearts (2561 ± 894 vs 727 ± 97, $p<0.0001$). Excellent positive correlation between intensity of 14C-methionine and 18F-FDG accumulation was observed ($r2 = 0.93$, $p<0.0001$). Contrast between inflammatory lesion and non-inflammatory area was higher in 18F-FDG than in 14C-methionine (3.45 ± 0.68 vs 2.07 ± 0.21, $p<0.05$). Conclusions: Using rat model of autoimmune myocarditis, we confirmed focal increased of 14C-methionine accumulation, co-localizing cardiac inflammatory lesions and 18F-FDG uptake. Further experiments using 11C-methionine PET are warranted to investigate the feasibility and robustness of in-vivo imaging and advantages over 18F-FDG PET especially regarding physiological background uptake issue.

OP433

Imaging of myocardial inflammation with somatostatin receptor based PET/CT - a comparison to cardiac MRI

C. Lapa[1], T. Reiter[1], X. Li[2], R. Werner[1], S. Samnick[1], R. Jahns[1], A. K. Buck[1], G. Ertl[1], W. R. Bauer[1]; [1]Universitätsklinikum Würzburg, Würzburg, GERMANY, [2]AKH Wien, Wien, AUSTRIA.

Aims: Acute myocarditis as well as post-ischemic myocardial inflammation are associated with a profound activation of the immune system that plays a pivotal role in the further clinical course. Present non- invasive imaging modalities allow no direct visualization of the involved macrophage system.We aimed to investigate the feasibility of somatostatin receptor (SSTR)-based positron emission tomography / computed tomography (PET/CT) for detecting acute inflammatory lesions in patients after myocardial infarction or peri-/myocarditis.MethodsOn a compassionate use base, 12 patients (7 males, 5 females) with active peri-/myocarditis (n=6) or sub-acute myocardial infarction (n=6) underwent SSTR-PET/CT imaging with 68Ga-DOTA-TOC and cardiac MRI within 3-10 days after onset of symptoms (mean, 7±3 days; interval between PET/CT and MRI, 3±3 days). PET images were visually scored. The AHA 17-segment model of the left myocardium was used for localization and comparison of inflamed myocardium for both imaging modalities. Using semi-quantitative analysis, tracer uptake was calculated as mean and maximum standardized uptake value (SUVmean and SUVmax) and compared to infarcted/inflamed myocardium with both remote myocardium and left ventricular (LV) cavity. Results: SSTR-PET/CT revealed areas with mild or moderately increased tracer uptake in the myocardium or the pericardium in all patients. In the 17-segment model, PET/CT yielded 55 and MRI 47 positive segments. Overall concordance of the 2 modalities was 85.3% (174/204 segments analyzed). In 9.3% (19/204), more positive segments were identified by PET/CT, whereas in 5.4% (11/204), MRI detected more positive segments. SUVmean and SUVmax in infarcted/inflamed areas were 3.5±0.9 and 4.0±1.1, respectively. The lesion-to-remote myocardium and lesion-to-LV cavity ratios were 1.9±0.4 and 1.9±0.3 for SUVmean and 1.8±0.3 and 1.7±0.3 for SUVmax, respectively. Conclusions: The different imaging patterns of SSTR-directed radiotracers and MRI suggest a complementary role of PET/CT for detecting/imaging myocardial inflammation in the course of myocarditis and/or sub-acute infarction. Our data warrant further analysis in larger prospective clinical studies.

OP434

Disphosphonates Cardiac Uptake in Familial Amyloid Neuropathy: Comparison between DPD and HMDP

H. Regaieg[1], R. De Paola Chequer[1], R. Ben Azzouna[1], V. Algalarrondo[2], B. Mahida[1], M. Slama[2], D. Le Guludec[1], F. Rouzet[1]; [1]Department of nuclear medicine, Bichat-Claude Bernard university hospital, Paris, FRANCE, [2]Department of cardiology, Antoine Béclère university hospital, Clamart, FRANCE.

Aims: Familial amyloid polyneuropathy (FAP) is a severe hereditary disease, due to production by the liver of a genetic variant transthyretin (TTR) resulting in tissue amyloid deposits. Cardiac involvement is of major prognostic value. Diphosphonate scintigraphy has been proposed as a diagnostic tool for TTR-related cardiac amyloidosis, but there is no consensus on the optimal radiopharmaceutical. Consequently, we compared the cardiac uptake of two 99mTc-labelled tracers: diphosphono-propanedicarboxylic acid (DPD) and hydroxymethylene

diphosphonate (HMDP) in patients with TTR-FAP. Methods: 122 consecutive patients with TTR-FAP were prospectively included and received randomly DPD or HMDP. Acquisitions (whole-body (WB) and chest SPECT) were performed 3 hours after intravenous injection of the tracer. Quantification of myocardial uptake on WB acquisitions was performed by use of the ratio between the geometric mean of either total or average counts of a region of interest (ROI) drawn over the heart area and the WB total or average counts (H/WBtotal or H/WBaverage). Quantification on SPECT acquisitions was performed by the ratio between 3D isocount volume of interest generated over the myocardium and a standard volume in the right lung (H/L). Quantification of soft tissues uptake was performed by use of ratio between average counts of a ROI drawn over the lumbar spine and a ROI drawn over soft tissues of the lower limb (B/ST) on the WB acquisition. Results: the DPD and HMDP groups of patients had similar age (62±15 vs. 59±14 years respectively; p=0.3), sex (males: 67% vs. 58% respectively; p=0.4), TTR mutation (Val30Met: 70% vs. 80% respectively; p=0.3) and activity of the tracer (DPD: 713±86 MBq vs. HMDP: 709±124 MBq; p=0.9). Quantitative parameters derived from whole body acquisition were significantly greater with DPD compared to HMDP (H/WBtotal: 3.8±2.7 vs. 2.4±2.1 respectively; p=0.002 and H/WBaverage: 5.2±2.2 vs. 4.3±1.3 respectively; p=0.01) as well as H/L derived from SPECT acquisition (3.9±3.7 vs. 2.0±1.9 respectively; p=0.001). The uptake by soft tissues was also greater in the DPD compared to HMDP group (B/ST: 3.6±2.0 vs. 5.7±2.9 respectively; p<0.0001). Conclusions: The present study shows that in patients with TTR FAP, the uptake of DPD in heart and other soft tissues is superior to that of HMDP. This suggests that DPD should be prioritized for initial assessment of patients suspected of cardiac involvement of TTR-related amyloidosis. Further study is required to assess whether this difference impacts the diagnostic performance and whether DPD is more accurate for the assessment of therapy response.

OP435

Cardiac involvement in systemic sclerosis patients can be detected by dual single-photon emission computed tomography of thallium-201 and iodine-123-beta-methyl-p-iodophenyl-pentadecanoic acid scintigraphy

S. Matsuo, K. Nakajima, S. Kinuya, K. Takahara; Kanazawa University Hospital, Kanazawa, JAPAN.

Objective: Systemic Sclerosis (SSc) is a clinically heterogeneous connective tissue disorder. Heart involvements confer a poor prognosis in patients with systemic sclerosis. Nevertheless, the prevalence of cardiac involvement is not fully evaluated. The purpose of this study was to detect myocardial metabolic and perfusion abnormalities at rest using 123I-BMIPP and 201Tl imaging in patients with systemic sclerosis patients. Methods: We examined 82 patients of collagen disease (male/female=18/64, mean age 55±14) (71 systemic sclerosis (SSs) (8 limited cutaneous SSc), 4 systemic lupus erythematosus (SLE), 5 mixed connective tissue disease (MCTD), 2 others). All patients underwent both resting 123I-BMIPP imaging and 201Tl imaging. Total defect score (TDS) of 123I-BMIPP and perfusion were semi-quantitatively determined with SPECT imaging using a 17-segment 5-point model and Japanese normal database. Mismatch was defined the difference of the score more than 2 (123I-BMIPP>201Tl). Left ventricular functional analysis was performed by QGS software. Results: Thirty-three out of 82 (40.7%) patients with collagen disease had metabolic abnormalities (defect score>3). TDS of 123I-BMIPP were 4.8±2.7 in patients with sclerosis and 201Tl defect score was 2.4±2.8 in sclerosis. Mismatch between 123I-BMIPP and 201Tl was found in 11 out of 82 patients (13.4%). Left ventricular ejection fraction was 69±16%, and end-diastolic volume 57±19ml, end-systolic volume 18±14ml. There was no perfusion-metabolic mismatch in patients with limited cutaneous SSc (n=8). Conclusion: Cardiac manifestation occurs earlier and frequently in an early stage systemic sclerosis patients with normal systolic function. The 123I-BMIPP metabolic SPECT can be utilized on systemic sclerosis patients.

OP436

Value of FDG-PET/CT and cardiac MR for the diagnosis and therapy monitoring in cardiac sarcoidosis.

B. SGARD, S. DJELBANI, J. TORDJMANN, G. POP, H. NUNES, D. VALEYRE, V. EDER, M. SOUSSAN; University paris XIII, Bobigny, FRANCE

Objectives: Cardiac sarcoidosis (CS) is associated with a poor prognosis. There are currently no clear recommendations on imaging strategy. The objective of this study was to compare FDG-PET/CT (PET) and cardiac MR imaging (MR) for the diagnosis and therapy monitoring of CS. Materials and Methods: We conducted a single-center retrospective study including 53 patients with histologically proven sarcoidosis and a suspicion of CS. PET and MR were performed in all patients in a maximum time interval of two months. PET were all performed after a low carbohydrate-high fat diet. A subgroup of 16/53 patients (30%), were followed during therapy using both MR and PET. MR was considered as positive if there was a delayed gadolinium enhancement located in the subepicardial area. PET was considered as positive if there was a focal or multifocal FDG uptake. The findings of PET and MR, as well as the reversibility under treatment were compared. Results: 36% of patients (n = 19/53) had a MR (+) and 13% (n = 7/53) had a PET (+). All patients with PET (+) had also an MR (+), with myocardial lesions located in the

same locations in all cases. Among patients, 30% (n=16/53) had residual physiological FDG uptake under therapy (diffuse, basal, papillary muscle). Among patients having baseline MR (+) and PET (+), 86% (n=6/7) had improving lesions on MR and 100% (n=6/6) on PET. None of the lesions in patients with MR (+) and PET (-) had modifications on follow-up MR. Conclusion: PET should be identify inflammatory CS and potential reversibility under treatment. PET should be systematically associated with MR for improving lesion characterization.

OP437

Relationship between active inflammation and myocardial injury in patients with cardiac sarcoidosis as detected by non-invasive multi-modality imaging

S. Kataoka, M. Momose, K. Fukushima, N. Serizawa, A. Suzuki, C. Kondo, K. Abe, S. Sakai, N. Hagiwara; Tokyo women's medical university, Tokyo, JAPAN

Aim: 18F-FDG PET/CT (PET), cardiac magnetic resonance (CMR) imaging and 123I-BMIPP/201TlCl dual myocardial SPECT have been reported to be useful to diagnose as cardiac sarcoidosis (CS), but the relationship between them is still poorly understood. The aim of this study is to clarify the relationship between the three modalities for CS. Materials and methods: We evaluated 16 patients (10 male, mean age 55±13 year old) with CS before steroid therapy who underwent PET, CMR and dual gated SPECT. Left ventricular myocardium was divided into 17 segments. BMIPP and TL defects were scored in each segment visually using a 5-point grading system: 0-4 (0,normal; 4,absent). BMIPP and TL total defect score was also calculated as summed BMIPP defect (BMDS), summed TL defect (TLDS) and summed mismatch score (MS). Late gadolinium enhanced (LGE) CMR and PET images were fused using a syngo.via software. Segmental FDG-SUVmax in the 17 regions as well as whole heart SUVmax were measured, and segmental LGE were assessed according to a 3-grading system (LGE0, no LGE; LGE1, partly positive LGE; LGE2, transmural LGE) on the fused images. All SPECT segments (17segs x 16 patients) were classified into the 3 groups of LGE score. Segmental BMIPP, TL defect, mismatch score and SUVmax were compared between the 3 LGE score groups using one-way ANOVA. Results: Whole heart SUVmax in the 16 patients was 6.6±5.0 and summed BMDS, TLDS, MS were 18.6±12.6, 12.9±10.9, 5.7±3.1, respectively. Segmental based analysis revealed that BMDSs were 0.49±0.95, 1.63±1.51, 2.57±1.60 in LGE0(n=156), LGE1(n=81), LGE2(n=35) (LGE0 <LGE1 <LGE2, $p<0.001$), and TLDSs were 0.33±0.76, 1.15±1.28, 1.86±1.44 in the 3 groups (LGE0 <LGE1 <LGE2, $p<0.005$), respectively. MSs in LGE1 and LGE2 groups were significantly higher than that in LGE0 group (LGE1, $p<0.001$; LGE2, $p<0.001$), but there was no significant difference in MS between LGE1 and LGE2. SUVmax in LGE1 group was significantly higher than that in LGE0 ($p<0.025$), but there was no significant difference in SUVmax between LGE1 and LGE2 groups. Conclusion: Higher SUVmax showing active myocardial inflammation was mainly located in the LGE region, where BMIPP-TL mismatch was observed. BMIPP-TL mismatch with higher FDG uptake still exists in the transmural LGE induced by granuloma, which may reflect injured but viable myocardium in the transmural LGE region among CS patients. The combination of the three modalities makes it possible to evaluate the morphological and pathophysiological aspects of CS.

OP438

Impact of 18F-FDG PET/CT in the management of patients with large vessel vasculitis associated to polymyalgia rheumatica.

C. Lavado-Pérez, I. Martínez-Rodríguez, I. Banzo, R. Quirce, J. Jiménez-Bonilla, M. De Arcocha-Torres, Z. Bravo-Ferrer, M. Jiménez-Alonso, J. L. López-Defilló, F. Gómez de la Fuente, D. Meza-Escobar, J. M. Carril; Nuclear Medicine. Molecular Imaging Group (IDIVAL). Marqués de Valdecilla University Hospital. University of Cantabria., Santander, SPAIN

Aim: Polymyalgia rheumatica (PMR) may present associated to large vessel vasculitis (LVV) that is often overlooked due to non-specific signs and symptoms. These patients frequently had a poor treatment response and need increased doses of steroids or other immunosuppressive drugs. Our aim was to evaluate the impact of 18F-FDG PET/CT in the management of LVV associated to PMR.Materials and methods: A prospective study including 40 consecutive patients with PMR (27 women/13 men, 68.10±10.27 years) was performed. An 18F-FDG PET/CT scan was requested on suspicion of associated LVV. PET/CT scan was obtained 180' after 18F-FDG intravenous injection. Images were evaluated using a visual analysis and grading the intensity of the vascular uptake from 0 (no uptake) to 3 (intense uptake). Five vascular regions were evaluated: supra-aortic trunks (SAT), thoracic aorta (TA), abdominal aorta (AA), iliac arteries (IA) and femoral/tibioperoneal arteries (FTA). A final diagnosis of LVV was established in 26 out of the 40 patients (65%), 20 of them were under therapy at the time of PET/CT examination. Results: The most frequently vascular region involved in the 26 patients with LVV was the TA (100%) followed by the SAT (61.54%) and the FTA (53.85%). The highest intensity of 18F-FDG uptake was at the TA (grade 2 and 3 in 24 patients). No uptake was visualized in any vascular region in 4 of the 14

patients without LVV (28.57%) and in the other 10 patients (71.43%) only a grade 1 uptake was observed in 1 or to 2 regions.18F-FDG PET/CT led to a therapeutic change in 17 out of the 20 (85%) treated LVV patients.Regarding the outcome in the 26 patients with LVV, 19 (73.08%) had a good clinical and biochemical response and a follow-up PET/CT performed in 8 of them showed a decrease of uptake. Despite an increase of treatment, 6 patients (23.08%) had a clinical and biochemical worsening and the follow-up PET/CT performed in 3 showed an increase of uptake. Finally, one patient (3.84%) in whom the treatment was not changed suffered a worsening.Conclusion: Our results confirmed the usefulness of 18F-FDG PET/CT for the detection of LVV associated to PMR. The most frequently involved region was the TA. The detection of vascular inflammation using 18F-FDG PET/CT had an important impact and led to a treatment change in a high percentage of patients with LVV.

Initial experience of DMSA SPECT-CT in the assessment of paediatric renal calculi

Ashford1, E Joel1, G Heath1, N Smeulders2, M Easty1, **L Biassoni**1Departments of Radiology1 and Urology2, Great Ormond Street Hospital for Children NHS Foundation Trust, London (UK)

Aim: Renal calculi are uncommon in children but, when they occur, they represent a significant cause of renal damage. Today, they are usually removed by percutaneous nephrolithotomy (PCNL), uretero-renoscopy or extracorporeal shock wave lithotripsy (ESWL). An abdominal radiograph and an ultrasound are the usual initial investigations but the position of the calculus may be incompletely defined. Aim of the study is to present our initial experience on ^{99m}Tc-DMSA with SPECT-CT in children with renal calculi. Methods: We performed DMSA SPECT CT in 19 consecutive children (age range 2–16 years, mean 9 years; 6 males, 13 females) with renal calculi. Calculi were diagnosed with ultrasound and abdominal x-ray. DMSA planar images were followed by SPECT and a low-dose CT. The split renal function, the renal parenchymal integrity, the number and position of calculi, and the Hounsfield Unit (HU) value of each calculus were noted. Two patients were scanned under general anaesthesia (GA); no sedation or GA was required in the other patients. The injected activity was calculated in proportion to body weight, scaling from a maximum of 100 MBq. The CT was acquired with 50 mAs, 80 kVp, tube rotation 0.8, collimation 2 x 1.5 mm, pitch 1.3, scan slice thickness 2mm. A topogram covering the abdomen and pelvis to detect possible stones in the ureters and bladder was performed in 11/19 (58%) patients (110 kVp, 36 mAs).Results: Renal scarring was demonstrated in 7/19 kidneys (37%), whilst 8/19 kidneys (42%) showed reduced renal function. SPECT helped to assess the integrity of the renal parenchyma adjacent to the calculus and to identify patients with chronic irrecoverable damage. The CT aided the location of the calculus within the collecting system. The stone density was pivotal in planning management (if <1000HU the patient was considered for ESWL, if >1000HU for PCNL). The effective dose equivalent (EDE) from the CT component was low (mean 0.36 mSv, range 0.21-0.75). The EDE from the topogram ranged between 0.016 and 0.032 mSv (mean 0.023). Conclusion: DMSA SPECT CT in paediatric patients with renal calculi provides both anatomical and functional information with very little extra radiation dose. These preliminary results are promising and deserve further evaluation.

OP440

99mTc-DMSA in Biopsy Confirmed Paediatric Acute Tubulointerstitial Nephritis

P. Zucchetta[1], E. Miorin[2], L. Murer[2], F. Bui[1], D. Cecchin[1], E. Vidal[2]; [1]Nuclear Medicine Dept. - University Hospital - Padova, Padova, ITALY, [2]Paediatric nephrology, dialysis and transplant - University Hospital - Padova, Padova, ITALY.

Acute tubulointerstitial nephritis (aTIN) is a frequent cause of acute renale failure in adults and children, accounting for 15-20% of acute kidney injury cases. Inflammatory cells infiltrating kidney interstitium, probably as a consequence of an antigen-initiated cell-mediated response, characterize it. Exposition to drugs, mainly non-steroidal anti-inflammatory drugs and antibiotics, is the most frequent etiology (70%), followed by viral and bacterial infections. Tubular dysfunction and a progressive reduction in glomerular filtration rate lead to renal impairment, which is usually reversed by timely treatment (elimination of the offending drug and steroids). Nevertheless, a delay in diagnosis and treatment may result in chronic tubulointerstitial nephritis, which can be steroid refractory. The clinical presentation is aspecific (fever, asthenia, etc) and there are no validated biomarkers. Imaging studies offer little contribution, since ultrasounds findings are usually not specific (kidney volumetric increase and diffuse cortical hyperechogenity) and 67Ga-citrate scintigraphy suffers of low specifity (50-60%) and significant radiation exposure, combined with long scanning times (48-72 h after injection). We have studied 5 patients (M4, F1, age range 3-17 y, age mean 15 y) diagnosed with acute tubulointerstitial nephritis. All patients presented acute renal failure, persistent fever (2-4 wk) and weakness. Diuresis was reduced in only one case.

Inflammatory markers were raised in all cases, with clear signs of acute kidney injury (creatinine clearance 55 ml/min/1.73 sqm) and tubular damage (glycosuria, elvated alfa1-microglobulin and NAG). Three cases had no of detectable causes (drugs, infection, immune system distrubances) and were classified as "idiopathic". One case developed uveitis two months later and was therefore classified as tubulointestitial nephritis-uveitis syndrome (TINU syndrome), whereas an Adenovirus infection was detected in the last one. All patients underwent 99mTc-DMSA scintigraphy during the acute phase of the illness. The scan was performed following the EANM procedural guidelines.Patchy hypofixation was observed in all cases, similar to some acute pyelo-nephritis patterns, but with bilateral involvement and a more diffuse distribution.Kidney biopsy has been performed in 4/5 patients, with kidney injury lasting > 6 wk. Histopathologic findings showed in all cases a typical inflammatory infiltration of the kidney interstitium.99mTc-DMSA scintigraphy could play a role in the diagnosis of acute tubulointerstitial nephritis, shortening the diagnostic work up and leading to a faster treatment. Considering the minimal radiation exposure and lack of invasivity it has promising perspectives also in the follow up of this underdiagnosed illness.

OP441

Evaluation of Schwartz eGFR-Cr in comparison with GFR measured by Tc-99m-DTPA clearance in healthy and in children with urinary tract infection with and without vesicoureteral reflux

M. Vlajković[1], S. Ilić[2], M. Rajić[1], M. Stević[1], M. Božinović[1], V. Živković[3], M. Matović[4]; [1]Center of Nuclear Medicine,Clinical Center Niš, Niš, SERBIA, [2]Center of Nuclear Medicine, Clinical Center Niš, Niš, SERBIA, [3]Clinic for Physical Medicine,Rehabilitation and Prosthetic, Clinical center Niš, Niš, SERBIA, [4]Center of Nuclear Medicine,Clinical Center Kragujevac, Kragujevac, SERBIA.

Objective: The aim of this study was to asses diagnostic performance of estimated glomerular filtration rate (eGFR-Cr) based on creatinine and body high equation originally developed by Schwartz. The assessment was done by means of comparison between glomerular filtration rate (GFR) measured by Tc-99m-DTPA clearance in children with no nephro-urological diseases, children with urinary tract infection without vesicoureteral reflux (VUR), and with VUR using Bland-Altman analysis.Material and Methods: The study enrolled 451 pediatric patients (104 male and 347 female, mean age 7.07±3.02 yrs, range 2-15 yrs), who were included in a retrospective review of GFR measurement data from the single institution's database. Subgroups of patients were formed according to the diagnosis as follows: control group (CG, n=64), group with urinary tract infection without VUR (UTI, n=299), and group with VUR (VUR, n=88). GFR was measured by Tc-99m-DTPA clearance method from a single blood sample drawn 180 minutes after radiopharmeceutical administration. eGFR was based on creatinine and body high equation. Results: Compared with GFR, the mean bias for eGFR-Cr in the study groups was as follows: CG: 1.937ml/min/1.73m2 (95% limits of agreement [LOA]: -36.759 to 40.633 ml/min/1.73m2), UTI: -3.010ml/min/1.73m2 (LOA: -57.292 to 51.272 ml/min/1.73m2) and VUR: 2.183mL/min/1.73m2 (LOA:-64.019 to 68.385 mL/min/1.73m2). eGFR-Cr demonstrated comparable accuracy to GFR in CG and UTI with 95% and 82% of estimates within 30% of GFR, while the estimates in VUR were less accurate, amounting to 68% of values within 30% of GFR.Conclusion: eGFR-Cr was found to be a reliable alternative to GFR in healthy children, as well as in those with urinary tract infection. However, it was found to be less accurate in children with vesicoureteral reflux and renal impairment.

OP442

Is the Clinical Diagnosis of Chronic Immune Thrombocytopenic Purpura in Pediatric Population Always Correct?

M. Todorovic-Tirnanic, D. Sobic-Saranovic, V. Artiko; Faculty of Medicine, University of Belgrade and Center of Nuclear Medicine, Clinical Center of Serbia, Belgrade, SERBIA.

Aim: 1. to investigate patophysiological mechanism of thrombocytopenia with ^{111}In-oxinate labeled autologous platelets in children with clinical diagnosis of chronic immune thrombocytopenic purpura (ITP); 2. to verify the diagnosis; 3. to predict the efficacy of the planned splenectomy. Material: 69 children (44 girls and 25 boys) aged from 3.1 -18.0 yrs (median = 11 yrs), body height: 100 - 187 cm (mean = 147 cm), body weight: 15 - 98 kg (median = 34 kg) were investigated. Methods: 1) 69 autologous ^{111}In-oxinate platelet (Pt) labelings; 2) 69 quality controls: a) general yield of labelling (GYL), b) differential yields of labeling (DYL): Pt DYL, red and white blood cell DYL, plasma DYL, c) initial platelet accumulation in the liver (IPAL); 3) Pt lifespan (LS); 4) Pt production index (PI); 5) Pt sequestration site and index estimation were performed. Results: Mean Pt blood count was 23 G/l (range: 1-122 G/l); mean blood sample volume for Pt separation and labeling was 55 ml (30 - 75 ml); mean radioactivity used for Pt labelling was 11.1 MBq; mean injected radioactivity was 6.7 MBq (2,6 - 10.1 MBq); mean GYL = 65.9 % (33.9 - 90.2 %); mean Pt DYL = 92.6 % (55.7 - 99.6 %); mean RBC&WBC DYL = 1.6 % (0.0 - 41.5 %); mean plasma

DYL =0.7 (0.2 - 7.3 %); mean IPAL = 11.9 % (3.0 - 35.8 %). Mean Pt lifespan was 12 hours (0.7 - 216 h). In 63/69 children (91.3 %) diagnosis of ITP was confirmed. In this group of children mean Pt lifespan was 9.6 h (0.7 - 93.6 h); mean Pt PI=1.8 (0.2 - 23.4); Pt sequestration site was: the spleen in 26 (42%), predominantly spleen in 9 (14%), liver in 3 (5%), mixed (in liver and spleen equally) in 24 (39%). In 6/69 (8.7 %) children clinical diagnosis of ITP was excluded. All of them had normal Pt lifespan: two had normal quantity of separated platelets (pseudothrombocytopenia) and four had inadequate Pt production (Pt PI ranged from 0.1 - 0.2). Conclusion: 1) In 6/69 children initial clinical diagnosis of ITP was changed: 2/69 had pseudothrombocytopenia, 4/69 inadequate platelet production. 2) In 63/69 children clinical diagnosis of ITP was confirmed. 3) Help in decision whether to perform splenectomy or not was enabled in 61% of confirmed ITP patients (with splenic, predominantly splenic and hepatic Pt sequestration).

OP443

Impact of colonic transit scintigraphy on clinical decision making in severely constipated children

E. Medaer, I. Hoffman, W. Thimister; KU Leuven, Leuven, BELGIUM

Aim: The objective of this study was to evaluate the diagnostic yield and the impact on clinical decision making of colonic transit scintigraphy in children with severe chronic functional constipation. Materials and methods: From September 2014 to March 2015, 7 patients (mean age 6.2 years, 4 girls and 3 boys) with chronic treatment-resistant functional constipation received an ^{111}indium-labeled diethylene triamine pentaacetic acid (^{111}In-DTPA) colonic transit scintigraphy in our institution. The scintigraphy was performed as part of the diagnostic work-up, with the aim of providing information on gastric emptying, small bowel transit and segmental colonic transit. After an overnight fast, patients ingested a small amount of water that was radiolabeled with ^{111}In-DTPA. They underwent repeated imaging in supine position between the detectors of a gamma camera to obtain anterior- posterior abdominal scans of 4 minutes duration each. The scans were taken at 4 h, 24 h and 48 h post-ingestion. Five technetium position markers were placed on anatomic landmarks to create a reference frame. Processing of the images was performed using the Hermes Hybrid Viewer and geometric centers were calculated. Results: Colonic scintigraphy showed normal transit time in 4 patients (57%), delay in the distal colon in 2 patients (29%), and colonic inertia in 1 patient (14%). This led to a diagnostic adjustment for 4 patients and a differentiation of the diagnosis for the 3 others. The results of the scintigraphy had therapeutic consequences for all of the patients. In 3 children (43%) the pharmaceutical treatment could be optimized. For3 other patients (43%) the planned intervention was altered. In 1 patient (14%) an operation could be avoided. Conclusion: This preliminary study demonstrates the added value of colonic transit scintigraphy in the investigation of functional constipation in children and the high impact on clinical decision making. Scintigraphic transit studies provide a noninvasive and safe assessment of whole-colon and regional colonic transit. Because of the physiological design and the reliability of the examination, we were able to offer diagnostic differentiation for all patients.

OP444

Accuracy of 99mTcO4- Meckel's Scan and Other Diagnostic Indicators in Symptomatic Paediatric Meckel's Diverticulum

Mazin Al Janabi1, Madan Samuel2,Andrea Kahlenberg3, Sujith Kumar41,4Department of Nuclear Medicine, 2Department of Pediatric Surgery, 3Department of Anaesthesia, Mediclinic City Hospital, Dubai, UNITED ARAB EMIRATES

Purpose: To evaluate the diagnostic accuracy of ^{99m}Tc-pertechnetate scintigraphy in children with symptomatic Meckel's diverticulum. Methods: This was a prospective linear observational study of 73 children with the diagnosis of symptomatic Meckel's diverticulum. Meckel's diverticulum scintigraphy was performed using ^{99m}Tc pertechnetate to evaluate ectopic gastric mucosa in MD in 61 (84%) children. Dynamic imaging was carried out for 60 minutes. Pharmacological intervention was not adopted to enhance the result of ^{99m}Tc-pertechnetate. Independent variables assessed were age, gender, weight-for-age z scores, clinical presentation, complications of MD, laparoscopy findings, haematology and biochemistry results, radiology, and histology. The sensitivity, specificity, positive & negative predictive values and accuracy of ^{99m}Tc-pertechnetate scintigraphy was assessed. Results: The incidence of MD with complications was 44%. The prevalence of ectopic gastric mucosa in histology specimens was 84%. There was a good correlation between rectal bleeding and presence of ectopic gastric mucosa (r = 0.94). Hematochezia associated with drop in haemoglobin (>2 g/dL) was diagnostic of MD with ectopic gastric mucosa in children (n=42; 58%. p = 0.006). Bilious vomiting was diagnostic of complicated MD (n=12; 16%. p = 0.007). ^{99m}Tc-pertechnetate scintigraphy sensitivity was 84% and specificity 22%. Positive predictive value was 0.64 and negative predictive value was 0.22. The accuracy of ^{99m}Tc-pertechnetate scintigraphy varies from 46% to 90%. The sensitivity and specificity of ^{99m}Tc-pertechnetate scintigraphy was dependent on the quantity and functional quality of the heterotopic gastric mucosa. Preoperative median z-scores was - 1.4 and postoperative median z-

scores were - 1.2. Conclusions: ^{99m}Tc-pertechnetate scintigraphy had a truncated predictive value. Its contribution in clinical decision making was poor. Clinical suspicion of MD should be high in children presenting with hematochezia associated with drop in haemoglobin by >2 g/dL. Laparoscopy is an effective diagnostic tool.

OP445

Clinical Value of Cerebral Perfusion SPECT Imaging in Children with Acute Sydenham's Chorea

S. M. d. A. Giorgio[1], M. G. Caprio[1], A. Romano[2], E. Vergara[1], G. Russo[2], M. Alessio[2], A. Cuocolo[1]; [1]Department of Advanced Biomedical Sciences, Naples, ITALY, [2]Department of Translational Medical Sciences, Naples, ITALY

Aim: Sydenham's chorea is the most common form of acute chorea during childhood ant it may be associated with cerebral perfusion abnormalities at SPECT imaging, mainly hyperperfusion or, more rarely, hypoperfusion patterns. We evaluated whether a better definition of cerebral perfusion patterns of the cortical/subcortical structures by SPECT imaging improves differential diagnosis and prognosis in pediatric patients with acute autoimmune Sydenham chorea. Material and Methods: Fifteen children (6 boys, age range 6-14 years) with a diagnosis of acute autoimmune chorea seen between 1999 and 2011 at our department were studied. Inclusion criteria were: presence of choreic movements with acute autoimmune etiology and age from 1 to 18 years. All patients had first a full physical examination including a rheumatologic and neuropsychiatric assessment. All patients also underwent brain magnetic resonance imaging (MRI) and cerebral SPECT imaging. MRI scan was performed with spin-echo T1 weighted, T2 weighted and FLAIR sequences. T1 weighted sequences were also obtained after administration of intravenous paramagnetic contrast (gadolinium). SPECT imaging was performed after intravenous injection of Tc-99m ethyl cysteinate dimer (32 Mbq/Kg) using a dual-head gamma camera (E-cam, Siemens Medical Systems) equipped with general purpose, low energy, parallel-hole collimator. The analysis was performed by comparing tracer uptake in the basal ganglia with the uptake in a control region. Results: At presentation, chorea was generalized in 9 patients and localized (hemichorea) in 6 patients. In addition to chorea, 6 subjects showed decreased verbal fluency and personality changes and one a left hemiparesis. Tests of liver and kidney function, antinuclear antibody, and anti-deoxyribonucleic acid were normal in all patients. Brain MRI revealed normal findings in 13 and small foci of white matter gliosis in 2 patients, without relevant clinical value. Cerebral SPECT showed unilateral increased perfusion in the basal ganglia in all 9 children with generalized chorea, while the remaining 6 patients had normal perfusion pattern. No relationship between the severity of the symptoms and the side of increased perfusion was found. A follow-up SPECT, performed during the recovery phase in 5 of the 9 patients with perfusion abnormalities at the first study, showed normal perfusion in all. Conclusions: The evidence of increased basal ganglia perfusion in during the active phase of the disease suggests that this abnormality is a marker of inflammatory chorea. Cerebral SPECT perfusion imaging could be an accurate noninvasive tool to monitor the course of acute autoimmune chorea in childhood.

Investigation of Image Quality with Sodium Pertechnetate ^{99m}Tc Produced by Cyclotron

S. V. Selivanova[1,2], É. Lavallée[1], O. Sarrihni[1], B. Guérin[1,2], É. Turcotte[1,2], R. Lecomte[1,2]; [1]Sherbrooke Molecular Imaging Center, CRCHUS, Sherbrooke, QC, CANADA, [2]Université de Sherbrooke, Sherbrooke, QC, CANADA.

Aim: Cyclotron production of technetium-99m (^{99m}Tc) is a promising route to supply ^{99m}Tc-radiopharmaceuticals. The main difference of cyclotron-produced ^{99m}Tc from generator source is its intrinsic contamination with shorter half-life ^{93}Tc, ^{94}Tc and longer-lived ^{95}Tc, ^{95m}Tc, ^{96}Tc, and ^{97m}Tc, which may affect image resolution and contrast. This study investigated the contamination due to the high-energy radioisotopic impurities present in sodium pertechnetate ^{99m}Tc produced with a cyclotron. Methods: Capillary and Jaszczak phantom imaging was performed using cyclotron-produced ^{99m}Tc (E_{in} = 24 MeV, 2 h irradiation, 99.815% ^{100}Mo enrichment) and ^{99m}Tc obtained from a generator up to 16 h after the end of production/elution. Radionuclidic/radioisotopic purity of the formulation was determined using gamma-ray spectrometry with calibrated HPGe detector and decay corrected to the imaging time. Planar images were acquired on a Discovery NM/CT 670 SPECT/CT camera (GE) equipped with low-energy high-resolution collimators. The energy windows were 140.5 keV ±7.5% (standard for ^{99m}Tc), 117.0 keV ±10% (low energy), and 170.0 keV ±10% (high energy). Results: For the main energy window, for a capillary filled with ^{99m}Tc-pertechnetate eluted from a generator, planar image resolution at full width half-maximum (FWHM) was 4.15±0.05 mm at 0 cm and 6.82±0.04 mm at 10 cm from the gamma-camera collimator. The FWHM resolution of images with cyclotron-produced ^{99m}Tc was 4.21 ±0.06 mm at 0 cm and 6.83±0.09 mm at 10 cm from the collimator. The resolution remained stable in time within measurement error. Planar images of Jaszczak phantom were of

comparable quality without significant loss in spatial resolution. On average, the contrast of images acquired using cyclotron-produced ^{99m}Tc (n=7) was 1.16±0.02 with contrast-to-noise ratio (CNR) of 10.47±0.26, which compares favorably to the best of two values obtained for generator ^{99m}Tc: 1.14 (contrast) and 10.28 (CNR). The relative count rate in high-energy window for the cyclotron-produced ^{99m}Tc increased up to 5-fold as compared to the generator ^{99m}Tc due to increased proportion of energetic ^{94}Tc and ^{96}Tc but remained below 10% of the total counts over the entire imaging period. Only marginal increase was observed in the low-energy window. Visually, two side-by-side images acquired with ^{99m}Tc from generator and cyclotron in the main energy window were found to be equivalent. Conclusions: At tested conditions, the scatter effect due to high-energy radioisotopic impurities present in ^{99m}Tc-pertechnetate produced with cyclotron did not influence visual image quality in the standard for clinical applications energy window. Early results of an ongoing clinical study (NCT02307175) confirm these findings.

One Size Fits All? Assessment of the Use of a Simple Calibration Protocol for Quantitative SPECT/CT Imaging of 177Lu in European Hospitals

J. Merrett[1,2,3], A. Fenwick[2], J. Scuffham[1,3], L. Johansson[2], A. Nisbet[1,3]; [1]University of Surrey, Guildford, UNITED KINGDOM, [2]National Physical Laboratory, Teddington, UNITED KINGDOM, [3]Royal Surrey County Hospital, Guildford, UNITED KINGDOM

The accuracy of molecular radiotherapy dosimetry calculations is critically dependent on the accuracy with which the quantitative imaging of the patient can be performed. However, there is no single established protocol for performing quantitative imaging. Therefore, the aim of this work was to assess the ability of a simple calibration protocol to quantify the activity in an unknown comparison source, simulating a relatively large lesion located within a patient in an area of warm background activity, in a number of hospitals across Europe.Two 177Lu sources were used at each hospital for this work, ranging from 30MBq to 100MBq at the time of imaging. All sources were filled at the UK National Physical Laboratory so the activities and activity concentrations were accurately known. A 16ml sphere was used to perform the calibration measurements: SPECT/CT acquisitions were performed of the sphere in an elliptical Jaszczak phantom in air, in water at the centre and in water off-centre. The comparison source was a 26ml central sphere, surrounded by an 80ml outer shell. The activity concentration ratio between the inner sphere and outer shell was approximately 15:1, providing a warm background. For the comparison exercise, the SPECT/CT acquisitions were also performed with the source positioned within a water-filled elliptical Jaszczak phantom with the addition of an anthropomorphic lung and spine insert and body contour rings that were added to the outside of the phantom. All image reconstruction was performed on a single Hermes Gold workstation using an OSEM algorithm with 5 iterations and 10 subsets. Images were corrected for scatter, attenuation and collimator-detector response. No corrections were performed for deadtime or partial volume effects due to the low activities and relatively large volumes used. Spherical volumes of interest of the physical size of the sources were used to extract total counts in all the SPECT images. A calibration factor was derived from the mean value (cps/MBq) of the three calibration measurements. This calibration factor was subsequently used to determine the activity within the central sphere in the comparison exercise. The data from the majority of the hospitals enabled the activity within the comparison source to be determined to within ±10%. This work demonstrated the ability of a single calibration protocol to be used successfully at a number of different hospital sites across Europe. It paves the way for harmonised calibration protocols to be developed, ensuring consistent patient treatment across all European hospitals.

OP448

Standardised Time-Dose Regimen for Ga-DOTANOC PET Imaging

J. K. J. Archer, M. J. Carroll, S. Vinjamuri, E. Panagiotidis; Royal Liverpool University Hospital, Liverpool, UNITED KINGDOM

Aim: The Royal Liverpool University Hospital (RLUH) has been established as a European Neuroendocrine Tumour Society (ENETS) Centre of Excellence for the last 5 years. Recently the department becoming one of the first in the UK to perform Gallium 68 (Ga68) DOTANOC PET as part of the diagnosis, pre-PRRT workup and post PRRT evaluation of such tumours. Although the local diagnostic reference level (DRL) is set at 200MBq, the time intensive production process and the short half-life of Ga68-DOTONOC (68 minutes) result in this rarely being achieved. At the RLUH the scanning radiographer attempts to compensate for this by adjusting the bed position times, resulting in highly variable image quality. This is further compounded by more usual factors such as variation in patient size. The aim of this project was to retrospectively inspect the administered activities and subsequent image quality for these patients, and develop a formalised activity-bed position time regimen that would help to standardise image quality at a more consistent level. Materials and Methods: A group of Ga68-DOTANOC patients (n = 50) scanned on the GE Discovery 690 at the RLUH were used to retrospectively inspect the variation in: injected activity, activity at scan start time, image quality, bed position time and patient dependent size parameters. Image quality was assessed by the signal-to-

noise ratio (SNR) calculated from standardised uptake values (SUV) measured in the spleen, an organ expressing homogenous tracer uptake. Results: The average administered activity was seen to be 132.6 ± 22MBq, the minimum activity being as low as 90.3MBq and the maximum that of the local DRL. The time from injection to scan start was seen to extend to a maximum of 36 minutes past the 1 hour window prescribed in the current protocol, resulting in a loss of 30.7% of the activity expected. 45 out of 50 patients exhibited a constant time per bed position, whilst 5 exhibited different times per bed position to optimise imaging of previously seen tumours. The spleen SNR ranged from 3.55 to 15.85, with mean of 10.45. Conclusions: Linear correlations have been made with specific indices that take into account the patient activity at scan time, the time per bed position and patient dependent size parameters. These indices have been rearranged to provide an optimum bed position time based on all the aforementioned factors. These have been verified with retrospective list mode reconstructions aiming for a consistent spleen SNR.

OP449

Evaluation of the Performance of a Biograph mCT-Flow PET/CT System according to NEMA NU2-2012 standards

I. Rausch[1], J. Cal-Gonzalez[1], T. Beyer[1], G. Minear[2]; [1]Center for Medical Physics and Biomedical Engineering, Medical University of Vienna, Vienna, AUSTRIA, [2]Dept of Nuclear Medicine, Landesklinikum St. Pölten, St. Pölten, AUSTRIA

Aim: To evaluate the physical performance of a Biograph mCT Flow PET/CT system with sequential and continuous patient table motion. Methods: We evaluated the performance of the Biograph mCT Flow 64-4R PET/CT system (Siemens Medical Solutions USA, Inc.). Spatial resolution, system sensitivity, noise equivalent countrate (NEC) and physical image quality (IQ) were assessed according to the NEMA NU 2-2012 standards. Resolution measurements were performed using an 18F-point source inside a glass capillary tube (inner diameter: 0.9-1.0 mm; wall thickness 0.4 mm). Sensitivity tests were performed with a 70cm long polyethylene tube filled with 4.5 MBq of FDG. Scatter fraction and count rate measurements were performed using a 70cm long polyethylene cylinder with a diameter of 20 cm, with a line source (1.04 GBq of FDG) inserted axially into the cylinder at 4.5 cm off-center. The standard NEMA IQ phantom with 6 spheres (internal diameter (mm): 10, 13, 17, 22, 28 and 37) was used for the evaluation of the IQ in whole-body imaging mode. First, the phantom was scanned over a single bed (4 min) according to the NEMA protocol. Second, a 2-bed position scan of 4 min each of the phantom with the image plane containing the spheres centered in the overlap region followed by a scan of the same axial scan field with Continuous Table Motion (CTM) at a table speed of 0.6 mm/s was performed. Image contrast and covariance for the six spheres in sequential and CTM mode were compared according to NU2-2012 regions. Measurements were done with a sphere-to-background ratio 8 to 1 and 4 to 1. Results: Spatial resolution measured as Full-Width-Half-Maximum (FWHM) was 4.3mm (r=1cm) and 7.8 mm (r=20cm). Measured sensitivity was 9.4 kcps/MBq, both at the center of the FOV and 10 cm off-centered. Measured peak NEC was 185 kcps at 29.0 kBq/mL. Scatter fraction was 33.5%.Sphere contrast recovery values (sphere-to-background of 8:1) varied from 42% (10mm) to 78% (37mm) for the NEMA protocol. No difference in contrast recovery values was seen between sequential and CTM acquisition. Background variability was slightly higher in CTM (between 2.4 and 6.3) compared to sequential mode (between 2.1 and 4.9). Conclusion: Basic performance (resolution, sensitivity, scatter, NEC) of the mCT Flow was equivalent to the performance of the predecessor mCT system. Contrast recovery in sequential and CTM acquisitions was similar, however, background variability was elevated slightly in CTM acquisition.

OP450

The effect of image reconstruction parameters in Mediso NanoScan PC PET/CT images obtained by two different positron emitting tracers under NEMA standards NU 4-2008

A. Gaitanis[1], E. Vlastou[1], P. Bouziotis[2], G. Kastis[3], C. D. Anagnostopoulos[1]; [1]Biomedical Research Foundation of the Academy of Athens (BRFAA), Athens, GREECE, [2]Institute of Nuclear and Radiological Sciences, Technology, Energy and Safety (I.N.Ra.S.T.E.S.) N.C.S.R., Athens, GREECE, [3]Research Center of Mathematics, Academy of Athens, Athens, GREECE

Aim: The Mediso NanoScan PC with 8 detector modules is a new commercially available small animal PET/CT scanner, suitable for both mice and rats imaging. To identify the optimum reconstruction approaches, we have assessed different image reconstruction parameters, for two different positron-emitting tracers under NEMA standards NU 4-2008. Materials and Methods: The scanner provides various reconstruction algorithms, however, in preclinical imaging, 3D OSEM (including a regularization method) is the most commonly used option. In this study, the combination of subsets (1, 2 and 4) and iterations (2, 4, 6, 8, 10) and the level total variation regularization (None, Low and High) were examined. All other reconstruction parameters such as coincidence mode, energy window, correction methods (attenuation and scatter) and voxel size were kept constant. For the image quality evaluation, all requirements of the NEMA standards were followed. The IQ

phantom was filled with 3.7MBq of 18FDG and after IQ phantom's cleaning and checked for zero activity, it was filled with 5.4 MBq of 68Ga. The acquisition time was thirty minutes for both positron emitters. For the quantitation of image quality, the following parameters were calculated: i) Recovery Coefficient (RC), ii) image noise (%STD), iii) spillover ratio (SOR) and iv) Contrast-to-Noise ratio (CNR). Results: The results indicate that the selection of the number of subsets can affect the RC values. As this number increases, the RC values increase and after a number of iterations, they remain unchanged (i.e. 2subsets/8iterations: RC1mm=0.05, RC2mm=0.22, RC3mm=0.67, RC4mm=0.83, RC5mm=0.92, 4subsets/8iterations: RC1mm=0.07, RC2mm=0.43, RC3mm=0.73, RC4mm=0.92, RC5mm=0.93). Furthermore, the level of regularization does not affect the RC values. Lower image noise is achieved using high level of total regularization (i.e. 4subsets/4iterations: 17.6% (Low), 6.6% (High)). The SOR values are improved as the number of subsets and iteration increases (i.e. 2subsets/2iterations: SORair & SORwater>0.25 and 4sub/2iter: SORair & SORwater <0.10). The CNR values depend on the number of subsets and the level of regularization (i.e. Low Regularization, 2subsets/4iterations: CNR1mm=0.18, CNR2mm=3.94, CNR3mm=15.76, CNR4mm=22.42, CNR5mm=27.88, High Regularization, 4subsets/4iterations: CNR1mm=1.11, CNR2mm=11.60, CNR3mm=28, CNR4mm=32.8, CNR5mm=35.2). Conclusions: Our findings demonstrate that selection of reconstruction settings should be determined by imaging requirements. To increased sensitivity, a 3D OSEM image reconstruction should be performed with low regularization level, four subsets and eight iterations. On the other hand, if high contrast images in low noise level are required, 3D OSEM image reconstruction should be performed with high level of regularization, four subsets and four iterations.

OP451

Considerations for Interpreting SPECT SUVs: Image Noise, Post-filter and SUV Metric

N. A. Bebbington[1], L. C. Jenkins[2]; [1]Queen Elizabeth Hospital Birmingham, Birmingham, UNITED KINGDOM, [2]HERMES Medical Solutions, London, UNITED KINGDOM

AIM: SUVs are used in PET to improve confidence in diagnosis and SPECT SUVs are now an emerging tool. Special consideration should be given to image reconstruction and interpretation of SPECT SUVs, due to inherent differences in resolution and noise between PET and SPECT. The reporting metric of choice may differ between these modalities: SUVmax is favoured in PET, but may not be appropriate for SPECT. The aim was to assess the effects of image noise and reconstruction settings on SUV and determine the most appropriate reporting metric. MATERIALS AND METHODS: The NEMA-IEC PET image quality phantom was filled with Tc-99m with a 6.7:1 sphere:background ratio. SPECT-CT data were acquired using a Siemens SymbiaT16/LEHR collimator (120x30sec projections, step-and-shoot with auto-contouring). Full-count SPECT data contained 8.4M counts. Poisson resampling was performed for a range of clinically realistic count densities (full down 1/16 counts). Data were reconstructed in HERMES HybridRecon v1.1B (with attenuation correction, scatter correction and resolution recovery) with a range of equivalent iterations and post-filters. These were analysed in HERMES HybridViewer v2.5. Spherical VOIs of nominal size were assigned to SPECT spheres. Three spherical VOIs (diameter 2.7cm) were placed in background. SUVmax and SUVpeak (1cc) were measured for all datasets. RESULTS: The true SUV of spheres was 6.7. Convergence: without post-filter SUVpeak was consistent with >90 iterations (>90% counts returned) for all spheres. At 30 iterations 55% counts were returned. Without post-filter SUVmax was less consistent with >90 iterations (>90% counts returned) for all spheres. At 30 iterations only 55% counts were returned. Increasing iterations is required for convergence but this increases noise. Variability: For the largest sphere (37mm diameter), as counts reduce SUVmax and SUVpeak increase. For an 8mm Gaussian post-filter SUVpeak increases by 51% from full counts to 1/16 counts, compared with 63% for SUVmax. This difference is reduced to 16% for a heavily filtered image. SUVpeak is most robust to varying count densities. CONCLUSIONS: SPECT data is more subject to effects of image noise and partial volume than PET, both of which cause variability in SUV. SUVpeak was the most robust SUV metric to image noise and is preferred for SPECT. It is important that noise and resolution are considered in the choice of post-filter. For studies with a large range in expected noise level, smoother filters are preferred.

OP452

Accurate model of a Capintec activity meter with the Monte Carlo code Fluka

F. Zagni[1], A. Evandri[1], G. Cicoria[1], A. Infantino[2], S. Vichi[2], S. Costa[3], M. Marengo[1]; [1]Medical Physics Department, University Hospital "S.Orsola – Malpighi", Bologna, ITALY, [2]Montecuccolino Nuclear Engineering Laboratory, Department of Industrial Engineering, University of Bologna, Bologna, ITALY, [3]PET Radiopharmacy Unit, University Hospital "S.Orsola – Malpighi", Bologna, ITALY

Aim. In this work we developed and validated a Monte Carlo model of one of the world's most diffused

radionuclide activity meters, using Fluka. Materials and Methods. We modelled the Capintec CRC-15, a widely diffuse model of activity calibrator. To this end, we used Fluka, a general purpose simulation code for radiation physics, covering an extended range of applications such as accelerator shielding, dosimetry and detector design. The main geometrical elements and materials of the ionizing chamber were included in the model. Thickness and position of internal components was evaluated through both direct measurements of external dimensions and CT/X-ray imaging. The radioactive sources were carefully modelled and located in the detector well; in the validation a set of reference sources was used: ^{137}Cs (22.7±1.5% MBq at time of measure), ^{133}Ba (1.3±1.5% Mbq), ^{131}I (71.5 ±1.5%), ^{57}Co (74.4±3%), ^{68}Ge "mock ^{18}F" (7.5±1.65%) and others. The container of each source and the correct filling were suitably modelled and included in Fluka input file. Calibration factors could be evaluated based on the energy deposited in the Argon gas. The entire decay scheme of each radionuclide was included in the simulations, including low-energy X-ray emission and the energy spectrum of beta particles. The results of the simulations (statistical error below 1%) were normalized to the response of the modelled ^{137}Cs source. The dependence of the sensitivity versus position of the source was also assessed in a range of 15 cm. Results. An high accuracy energy-response curve for the activity meter was calculated, allowing for prediction of an initial calibration factor for new radionuclides. In the benchmark against known standards, the ratio between simulated and measured relative response was: ^{133}Ba 1.007±0.015, ^{68}Ge 1.016±0.018, ^{131}I 0.971±0.017, ^{57}Co 0.970±0.035. The sensitivity-position curve gave 4% as a maximum discrepancy. Conclusion. An accurate model of a widely diffuse activity meter has been validated for a variety of gamma-emitting nuclides, covering a wide range of energies and source positions, showing discrepancies below 3% for all the tested sources. The Fluka code proved to be a powerful tool for assessment of activity meter's calibration factors for radionuclides commonly used in radiopharmacy facilities as well as for non-conventional radionuclides, and for the easy assessment of geometrical correction factors.

OP453

Phase I Trial comparing a Digital Detector PET/CT System with current photomultiplier PET Technology in Diagnostic Oncology

M. V. Knopp[1], K. Binzel[1], C. L. Wright[1], V. Nagar[1], P. Bardos[1], P. Maniawski[2], J. Zhang[1]; [1]The Ohio State University, Columbus, OH, UNITED STATES, [2]Philips Healthcare, Cleveland, OH, UNITED STATES.

Objectives: The commercial introduction of a solid state, digital photon counting PET detector PET/CT system presents a potential next generation leap that requires objective assessment of clinical capabilities. This Phase I trial was performed to demonstrate the potential clinical capabilities for oncologic whole body imaging and to recommend acquisition approaches. Methods: 40 patients volunteered to participate in an intra-individual matched pair comparison study using a digital PET/CT (Vereos, Philips Healthcare Cleveland) while their standard of care PET/CT exam was performed on a conventional photomultiplier TOF PET/CT system (Gemini 64 TF) at 75 min p.i. PET imaging was performed using a standard of care 480 MBq FDG dose. Ultra-low dose CT attenuation scans were acquired on the digital PET/CT using 120 KV, 50 mAs using iterative iDose4 reconstruction. PET emission was acquired with 90s per bed position, 39% overlap and 164 mm z-axis FOV and reconstructed using TOF with default 4x4x4, 2x2x2 and 1x1x1 mm voxel volumes using PSF and Gaussian filtering. The digital PET/CT system has also an improved time of flight (TOF) timing resolution of 320 ps vs. 550 ps in the comparator conventional system. Blinded visual and clinical read assessment was performed by a three reader panel independently. Results: All 40 patient studies were rated to be of evaluable image quality. The digital PET comparator scan was classified preferable in regard to count intensity and tissue delineation detail in all case comparisons. The confidence of lesion detection increased on the DPET scans with increased reconstruction matrix size, with significantly ($p \leq 0.05$) improved lesion characterization between the 4 and 1 mm comparators. Most pronounced differences were noted in small and intense lesions such as lymphnode metastases and small pulmonary nodules. No increase in non-specific uptake of lesions was noted on the higher resolution reconstruction matrices. Faster and lower dose acquisition approaches appear feasible as dose reduction simulations of up to 70% did not impact diagnostic assessability. Conclusions: The digital detector PET/CT demonstrated consistently preferable imaging features in the intra-individual comparison with improved lesion characterization most notable in small, metabolically active lesions. Whole body PET imaging with higher resolution matrix size appear readily feasible with digital PET leading to substantially reduced partial volume effects, thus improving lesion detectability and characterization of heterogeneous lesions. The 2mm / 288 reconstruction matrix appears to be the recommended standard to be utilized with the 1mm / 576 available for high definition images.

The role of 18F-FDG PET/CT for the detection of recurrent Osteosarcoma

F. Ceci[1], A. Angelini[2], P. Castellucci[1], T. Graziani[1], M. Polverini[2], P. Ghedini[1], S. Israel[1], R. Bonfiglioli[1], P. Ruggieri[2], S. Fanti[1]; [1]Nuclear Medicine - S.Orsola-Malpighi Hospital - University of Bologna, Bologna, ITALY, [2]Department of Orthopedics, Istituto Ortopedico Rizzoli, University of Bologna, Bologna, ITALY.

Aim: To investigate the diagnostic accuracy of 18F-FDG-PET/CT in osteosarcoma patients, with suspicious of disease recurrence after radical therapies. Materials and Methods: Inclusion criteria were: a) radical surgical treatment for proven osteosarcoma and documented complete remission after therapy; b) 18F-FDG-PET/CT during follow-up for clinical/diagnostic suspicious of relapse; c) histological validation of 18F-FDG-PET/CT findings. Thirty-seven osteosarcoma patients were retrospectively enrolled (20 male, 17 female; mean/median/range age 21/18/7-72 years-old). The primary sites of tumours were: femur (n=15); tibia (n=13); humerus (n=3); soft tissue (n=3); pelvis (n=2); ulna (n=1). 18F-FDG-PET/CT performance was assessed with a per-patient and per-site evaluation of sensitivity, specificity, accuracy, positive predicting value (PPV) and negative predicting value (NPV). The sites of relapse were classified as local (local relapse in bone and/or soft tissue), lung, lymph-nodes (LNs) and distant (other skeletal segments and/or distant soft tissue). The disease free survival (DFS) and the overall survival (OS) after 18F-FDG-PET/CT were evaluated. Results: 18F-FDG-PET/CT was positive in 89.2% (33/37) of patients. Local uptake was observed in 35.1%patients (13/37); lung uptake in 18.9% (7/37); local and lung in 2.7% (1/37); local and LNs in 10.8% (4/37); local, LNs and distant 5.4% (2/37); LNs and distant in 2.7% (1/37); lung, LNs and distant in 2.7% (1/37); local, LNs, lung and distant in 5.4% (2/37); lung and distant in 2.7% (1/37); only distant in 1/37 (2.7%). The per-site mean-SUVmax analysis resulted in: local=10.2; LNs=8.2; lung=5.6; distant=9.8. In order to validate 18F-FDG-PET/CT findings, all patients underwent surgery on the basis of 18F-FDG-PET/CT results. Histology resulted positive in 92% (34/37) of patients. A total of 51 pathologic lesions were evaluated (22 local relapse, 11 lung metastasis, 10 metastatic LNs, 8 distant metastatic lesions). On a per-patient analysis 18F-FDG-PET/CT showed a sensitivity, specificity, accuracy, PPV and NPV of 91%, 75%, 89%, 97%, 50%. On a per-site analysis the performance for local recurrence was 96%, 100%, 97%, 100%, 93%, while for lung recurrence detection was 80%, 100%, 92%, 100%, 88%. The mean follow-up after 18F-FDG-PET/CT was 21.5 months (range 1-82). At the end of follow-up 19% (7/37) of patients were death, 35% (13/37) were alive with disease and 46% (17/37) had no evidence of disease. At 18 months after 18F-FDG-PET/CT the DFS was 46% and the OS was 81%. Conclusion: 18F-FDG-PET/CT showed promising results for the recurrence detection in osteosarcoma patients with suspicious of relapse after radical treatment, particularly in the detection of local relapse and lung metastasis.

OP455

Initial FDG PET/CT predicts survival in adults ewing sarcoma family of tumors.

J. B. Bastien; B Jamet1, T Carlier1,2, L Campion3, E Bompas3, M Colombié4, D Rusu4, D Goulon4, V Fleury4, F Kraeber-Bodéré1,2, C Rousseau2,4, 1Nuclear Medicine Unit, University Hospital, Nantes, France, 2INSERM U892, CRCNA, Nantes, France, 3Oncology Unit, ICO Cancer Center, Saint Herblain, France, 4Nuclear Medicine Unit, ICO Cancer Center, Saint Herblain, France

AIM: FDG PET/CT is a recommended tool for initial staging and restaging of Ewing Sarcoma Family of Tumors (ESFTs). However, the use of baseline FDG PET/CT as a tool for assessing survival outcome was not yet reported. We evaluated the benefit of using quantitative PET-based parameters to predict the survival outcome of ESFTs patients. MATERIALS AND METHODS: 20 adult patients (10 men and 10 women) with ESFTs, treated according to Euro-Ewing 99 protocol, were retrospectively included. The primitive lesion of each patient was analyzed using different quantitative parameters: SUV (maximum, peak and mean), metabolic tumor volume (MTV) and total lesion glycolysis (TLG) before treatment. Kaplan-Meier method, Logrank tests and univariate Cox analyses were used to calculate survival curves and to analyze whether imaging and usual clinical prognostics factors (metastatic disease at presentation, axial tumor location, tumor size>10cm, sex and age≥20 years) could predict progression free survival (PFS) and overall survival (OS). RESULTS: The median age was 23 years (range, 16 to 61). Twelve patients were initially metastatic (lungs or bone marrow). For 10 patients, the disease location was osseous and for 10 non osseous (4 of them were PNET). Parameters data of 19 patients were interpretable. Univariate analysis showed different imaging parameters as predictors of OS: SUVmax (HR: 1.16; 95% CI: 1.02-1.33; P=0.021), SUVpeak (HR: 1.27; CI: 1-1.61; P=0.047), SUVmean (HR: 1.31; CI: 1.04-1.66; 0.024). Three years OS was 53% for SUVmax< 17 vs 25% for SUVmax>17 (P= 0.021). SUVmax (P=0.044), SUVpeak (P=0.027) and SUVmean (P=0.027) were predictive of PFS for univariate analysis. MTV and TLG were not predictive for PFS and OS. For clinical parameters at baseline, metastatic disease (HR: 13.5; CI: 1.55-102.15; P<0.001) and male sex (HR: 6.01; CI: 1.24-29.14; P=0.026) shortened only PFS.

CONCLUSION: At baseline, FDG PET with SUVmax, SUVpeak and SUVmean measured on primitive lesion could be a useful tool to predict OS and PFS for adult ESFTs patients.

OP456

Soft tissue sarcomas: Comparison between visual assessment and metabolic parameters in FDG PET/CT

D. Lopez, A. Domenech, C. Achury, R. Jaller, J. Duch, M. Estorch, A. Flotats, I. Carrió; Nuclear Medicine department. Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN

PURPOSE: To compare metabolic tumor parameters (Maximum Standard Uptake Value [SUVmax], Mean Standard Uptake Value [SUVmean], Metabolic Tumor Volume [MTV] and Total Lesion Glycolisis [TLG]) derived from 18F-FDG PET/CT with visual assessment in order to correlate with the clinical course of soft tissue sarcoma. MATERIALS AND METHODS: Eleven patients (p) [8 males; mean=49 y/o, range 23-67] with soft tissue sarcoma, histopathologically confirmed (5 fusocellular, 1 leiomyosarcoma, 4 lyposarcoma and 1 myxofibrosarcoma), who underwent baseline (before chemotherapy, surgery and radiotherapy) and early (after treatment) follow-up 18F-FDG PET/CT were retrospectively reviewed. Visual and Quantitative analysis were done in baseline and early follow-up PET/CT comparing the results with the late follow-up scan visual analysis. Based on visual assessment of the early follow-up PET/CT patients were considered to be in local recurrence (LR), disease progression (DP), stable disease (SD) and partial response to treatment (PR). Quantitative measurements to track changes in tumor volume and metabolic activity were performed using Philips *Tumor Tracking Application*, determining the SUVmax, SUVmean, MTV and TLG. Late follow-up scans (PET/CT and/or MRI) performed in a period of no more than 6 months after the last PET/CT were reviewed in order to assess the clinical course of the tumor. RESULTS: In the visual analysis, 2p were considered in LR, 3 in DP, 3 in SD and 3 PR. In the quantitative analysis, 1p visually considered in LR and 2 of the 3 in DP presented an increase in SUVmax, SUVmean, MTV and TLG, while the remaining patients in LR and in DP presented an increase in SUV values and a decrease in MTV and TLG. In 2 of the 3p considered visually in SD, a decrease of all the metabolic parameters was observed and no changes were seen in 1p. Two of the 3p in PR presented a decrease in all values while 1 had a decrease in SUV values and a minimum increase in TLG. Late imaging follow-up scans in the 2p with SD and a decrease in metabolic tumor parameters showed PR while in the remaining 9p no changes were seen between scans. Overall, a correlation between metabolic tumor parameters in the baseline and early follow-up PET/CT with the late follow-up scan visual analysis was observed in 63% (7/11) of the patients. CONCLUSION: In addition to the visual analysis, the metabolic parameters could be a useful tool to evaluate with more accuracy the clinical course of soft tissue sarcomas.

OP457

Tumour heterogeneity for differentiation between tumour and normal liver tissue in FDG-PET imaging

L. Jaritz[1], H. Ahmadzadehfar[1], M. Essler[1], N. Zsoter[2], L. Papp[2], F. Gaertner[1], R. A. Bundschuh[1], L. Thomas[1]; [1]Department of Nuclear Medicine, Universitaetsklinikum Bonn, Bonn, GERMANY, [2]Mediso Medical Imaging Systems, Budapest, HUNGARY

Introduction: In process of planning internal/external radiation-therapy it is essential to determine tumour-volume as accurate as possible. Therefore it is essential to differentiate benign from malignant tissue best possible. FDG-PET/CT has the ability to distinguish between metabolic active tumour and surrounding tissue by means of measured activity-uptake. By use of textural analysis based on a image-analysis of FDG-PET/CT images, structural features can easily be extracted. We investigated, if these textural parameters, which reflect the heterogeneity, function as a tool for differentiation between benign and malignant tissue and analysed the variability of heterogeneity within a tissue. Methods: 43 patients with liver-metastasis of colorectal-carcinomas have been examined on baseline FDG-PET/CT-scans before their first selective internal radiotherapy. In FDG-PET images liver metastasis and normal liver tissue were analysed with InterviewFusion-software (Mediso). Three volumes-of-interest (VOIs) with a fixed diameter of 25mm were drawn in healthy liver tissue, whilst metastasis were manually delineated. For determination of the tumour heterogeneity within these VOIs we calculated 30 different textural parameters including Entropy, Homogeneity and Contrast. For better comparison we measured established parameters used in clinical routine (mean and max standardized uptake values (SUVmean/SUVmax)). For statistical analysis we compared the heterogeneity in terms of intra-patient-variability and inter-patient-variability. Students-T-test was used to compare the parameters for healthy and pathological tissue. Results: The mean relative standard-deviation as measure for intra-patient-variability was found to be lowest for Busyness (2.4%), Homogeneity (5.1%), Correlation (7.8%), and Entropy (8.0%). These values were comparable with the ones for routine parameters SUVmax (7.5%) and SUVmean (6.9%). The mean inter-patient-variability was found to be lowest for Busyness (3.8%), Correlation (6.1%), Short Zone Emphasis (9.1%), and Homogeneity (11.9%). These were lower than the variability for SUVmean (20.7%) and SUVmax (18.9%). For differentiation between healthy liver-tissue and tumour we found 26 of the 30 textural

parameters statistically significant ($p<0.05$), highest significance was found for Homogeneity, Short Run Emphasis, Intensity Variation, and Short Zone Emphasis. SUVmean and SUVmax also showed ability to differentiate but with a lower statistical significance. Conclusion: In healthy liver tissue we found a intra-patient-variability comparable to the conventional SUVmax and SUV mean while for inter-patient-variability some textural parameters showed even lower values than the routine parameters. Furthermore most of the textural parameters showed better ability to differentiate between malignant and healthy tissue than the SUVmean and SUVmax. Therefore textural parameters are promising for classification lesions as well as to delineate malignant tissue for treatment-planning or response-evaluation.

OP458

Factors of FDG uptake in the liver and blood pool on PET scans

K. Zhou, **Sr**.; West China Hospital of Sichuan University, Chengdu, CHINA

Factors of FDG uptake in the liver and blood pool on PET scansObjectives: It was reported that the standardized uptake value (SUV) of 18F-FDG in children was lower than that of in adults on PET. But the correlation between SUV and age was unknown. The objective of present study was to find is there a correlation between SUV and age. Methods: Three hundred and seventy-eight patients (male 210, female 168) who received whole body 18F-FDG PET scans were included based on inclusion and exclusion creteria. In which, 230 had malignancy(171 lymphoma), and the others were healthy but for cancer screening. The age of them were 2-40 years (3 and 5 cases for 2 and 3 years, 10 cases for the rest). The correlations between SUVmax and SUVmean from liver and blood and gender, age, body weight, serum glucose and administration dose were analyzed uni- and multivariately. Then the independent factors were correlated with SUVs using curve estimation regression. Results: Univariate analysis revealed that there were positive correlations between SUVs and age, body weight, serum glucose and administration dose ($p<0.05$). There was no correlation between gender and SUVs ($p=0.612$). But only body weight and age had positive impact on SUVs after multivaraite analysis ($p<0.05$). Curve estimation showed the SUVs increased along with the age before 25 years, then it reached a platform. And the SUVs increased along with body weight without a platform. Conclusion: Both Age and body weight are independent factors on FDG uptake. SUVs increase along with the age before 25 years, then it reach a platform. And the SUVs increase along with body weight without a platform.

OP459

18F-FDG PET/CT role in staging of gastric carcinomas: comparison with conventional Contrast Enhancement Computed Tomography.

C. Altini, **A. Niccoli Asabella**, A. Di Palo, M. Fanelli, D. Rubini, C. Ferrari, A. Notaristefano, G. Rubini; Nuclear Medicine Unit, D.I.M., University of Bari "Aldo Moro", Bari, Italy, Bari, ITALY.

Aim: to evaluate the role of 18F-FDG PET/CT in staging gastric carcinoma comparing it with Contrast Enhancement Computed Tomography (CECT) and if morphological and functional parameters might give a contribution. Materials and methods: This retrospective study included 45 patients who underwent whole body CECT and 18F-FDG PET/CT before any treatment. We calculated CECT and 18F-FDG PET/CT sensitivity, specificity, accuracy, positive and negative predictive values (PPV and NPV) for gastric, lymphnode and distant localizations; furthermore we compared the two techniques by McNemar test. Linear regression was performed to evaluate SUVmax and SUVmean in relation to gastric lesion size. The role of 18F-FDG PET/CT semiquantitative parameters in relation to histotype, grading and site of gastric lesions were evaluated by ANOVA test. Results: sensitivity, specificity, accuracy, PPV and NPV of CECT and 18F-FDG PET/CT for gastric lesion were respectively 92.11%, 57.14%, 86.66%, 92.11%, 57.14% and 81.58%, 85.71%, 82.22%, 96.88%, 46.15%. No differences were identified between the 2 techiques about sensitivity and specificity. No stastistical differences were observed between PET parameters and histotype, grading and site of gastric lesion. The mean value of the maximum diameter was 52.59 mm (range 4 - ≥100). Considering 30 mm, as a threshold value for maximum diameter we divided patients in 2 groups: size ≤ 30 mm and size > 30. In 15/45 pts size was ≤ 30 mm and 18F-FDG PET/CT sensitivity and specificity resulted respectively 33.33% (95%CI: 7.88% to 69.93%) and 83.33% (95%CI: 36.10% to 97.24%). In 30/45 pts size was > 30 mm and 18F-FDG PET/CT sensitivity and specificity resulted respectively 96.55% (95%CI: 82.17% to 99.42%) and 100% (95%CI: 16.55% to 100%). SUVmax and SUVmean resulted positively related to lesion dimension (SUV max=3.53+0.11*lesion size, F=8.91, p=0.005; SUV mean=1.99+0.06*lesion size, F=7.07 p=0.01) No stastistical differences were observed between PET parameters and histotype, grading and site of gastric lesion. The results of CECT and 18F-FDG PET/CT about lymphnode involvement were 70.83%, 61.90%, 66.66%, 68%, 65% and 58.33%, 95.24%, 75.55%, 93.33%, 66.67%. The results of CECT and 18F-FDG PET/CT about distant metastases were 80%, 62.86%, 66.66%, 38.10%, 91.67% and 60%, 88.57%, 82.22%, 60%, 88.57%. 18FDG PET/CT specificity was significantly higher both for lymphnode and distant metastases.

Conclusions: the 18F-FDG PET/CT is a useful tool for the evaluation of gastric carcinoma to detect primary lesion, lymphnode and distant metastases using one single image whole-body technique. Integration of CECT with 18F-FDG PET/CT permits a more valid staging in these patients.

OP460

Utility of 18F-FDG PET/CT in Patients with Advanced Squamous Carcinoma of Uterine Cervix Receiving Concurrent Chemoradiotherapy: A Parallel Study of a Prospective Randomized Trial

F. Liu[1], C. Lai[1], L. Yang[1], C. Wang[1], G. Lin[1], C. Chang[2], S. Huang[3], Y. Huang[4], N. Peng[5], J. Hong[1], A. Chao[1], H. Chou[1], Y. Chang[1], T. Yen[1]; [1]Chang Gung Memorial Hospital and Chang Gung University College of Medicine, Taoyuan, TAIWAN, [2]Chang Gung University, Taoyuan, TAIWAN, [3]Chang Gung Memorial Hospital and Chang Gung University College of Medicine, Kaohsiung, TAIWAN, [4]Chang Gung Memorial Hospital and Chang Gung University College of Medicine, Chiayi, TAIWAN, [5]Kaohsiung Veterans General Hospital, Kaohsiung, TAIWAN

Aim: This study aimed to evaluate the utility of pre- and during-treatment 18F-fluorodeoxyglucose (18F-FDG) PET/CT in predicting failure patterns in patients with advanced uterine cervical cancer receiving concurrent chemoradiotheray (CCRT). Materials and methods: Patients with cervical squamous carcinoma, FIGO stage III-IVA or pelvic/paraaortic lymph node (LN) metastasis without other distant metastasis defined by 18F-FDG PET/CT entering a randomized controlled trial of CCRT (AGOG09-001) were eligible for this parallel study. PET/CT scans were performed at baseline, during week 3 of CCRT and 2-3 months after CCRT. PET/CT parameters included maximal standardized uptake value (SUVmax), metabolic tumor volume (MTV), SUVnode (largest SUVmax of all positive LNs), SUVratio (during-treatment SUVmax / pre-treatment SUVmax * 100%), and MTVratio. The Mann-Whitney U test and receiver operating characteristic curves were used to evaluate the potential predictors, and another independent patient dataset was used for validation. Results: Early treatment failure (within 6 months) was noted in 9 of 55 (16.4%) patients eligible for analysis. Both pre- and during-treatment cervical tumor volumes ($P < .001$) were significant predictors of local failure ($n = 4$). During-treatment SUVnode ($P = .019$) and maximal SUVratio of LNs ($P = .024$) were significant predictors of regional failure ($n = 4$). Distant failure was present in 5 patients, with during-treatment SUVnode ($P = .027$) and MTVratio of the cervical tumor ($P = .033$) as significant predictors. Conclusion: Pre- and during-treatment PET/CT may be useful in predicting early treatment failure patterns, thus early therapeutic modifications (locoregional and systemic) can be applied accordingly in hope for outcome improvement.

OP461

Face-To-Face 18F-FDG-PET/CT and CA125 (Serums Levels and Kinetic Values) in Patients with Suspected Recurrence of Ovarian Cancer.

A. Palomar Muñoz, J. M. Cordero García, G. A. Jiménez Londoño, M. P. Talavera Rubio, M. E. Bellón Guardia, B. González García, V. M. Poblete García, Á. Soriano Castrejón; Hospital General Universitario de Ciudad Real, Ciudad Real, SPAIN

PURPOSE: The aim of this study was to evaluate the capability of 18F-FDG-PET/CT in the detection of recurrences in ovarian cancer, when compared with CA125 serum levels, as well as the diagnostic influence of CA125 velocity (CA125v) and CA125 doubling time (CA125dt) in the PET/CT results. METHODS: A total of 54 women with suspicion of relapse, studied with a standard 18F-FDG-PET/CT and CA125 serum level were retrospectively studied. Patients were grouped according to CA125 normal serum levels before the PET/CT in 2 groups (1: CA125<35 IU/ml, 2: CA125>35 IU/ml).The final diagnosis was obtained by histological analysis or clinical follow up greater than 6 months. A total of 37 patients had at least two determinations of CA125 levels, which allowed to calculate CA125v and CA125dt, that were independently analysed. These patients were compared with the FDG-PET/CT results, classified as positive (A) and negative (B). RESULTS: PET/CT detected relapse in 45/54 (83.33%) patients, and was negative in 9/54 (16.66%) women, with only 1 false negative result, reaching a sensitivity of 97.83% and specificity of 100%. In contrast, attending to the CA125 levels, 35/54 (64.81%) patients were included in the group 1, and 19/54 (35.18%) in the group 2, with a sensitivity of 73.33%, and a specificity of 77.78%. In the group 1 (median 10.9, 5.2-33.9 IU/ml) PET/CT classified correctly 18 patients (7 negative, 11 positive), and 1 false negative. In the group 2 (median 69.9, 35.5-1950.9 IU/ml) PET/CT detected disease in 33 patients, without misdiagnoses. Regarding to the kinetic values, the A group composed by 28 patients showed a median CA125v of 5.17 (-0.05-87.03) and a median CA125dt of 3.71 (-175.03-32.66). The nine women included in the B group had a median CA125v of 0.27 (-0.56-364.05) and a median CA125dt of 2 (-148.6-23.22). No statistical differences were found between both groups concerning to the kinetics parameters (CA125v p=0.2, CA125dt p=0.3). CONCLUSION: The 18F-FDG-PET/CT shows a high diagnostic performance in the suspicion of ovarian cancer recurrence, regardless the levels of CA125 and the kinetic values. Thus, in case of clinical suspicion of ovarian cancer relapse, seems to be essential to carry out an FDG-PETCT study in all cases.

Simultaneous PET/MR imaging with FDG for the evaluation of symptomatic patients with non-stenotic carotid atherosclerotic plaques

F. Hyafil[1], A. Schindler[2], D. Sepp[3], T. Obenhuber[2], S. Höhn[2], S. Nekolla[1], M. Dichgans[3], M. Schwaiger[1], T. Saam[2], H. Poppert[3]; [1]Department of Nuclear Medicine, Klinikum rechts der Isar, Munich, GERMANY, [2]Ludwig-Maximilians-University Hospital Munich, Institute for Clinical Radiology, Munich, GERMANY, [3]Department of Neurology, Klinikum rechts der Isar, Munich, GERMANY

Introduction. High-resolution magnetic resonance imaging (MRI) can assess atherosclerotic plaque composition in carotid arteries with good correlation to histopathology. 18Fluorodeoxyglucose (18F-FDG) is a positron emission tomography (PET) radiotracer that accumulates in inflammatory cells present in atherosclerotic plaques. The aim of this study was to investigate in 18 patients with ischemic stroke classified as cryptogenic and presenting non-stenotic carotid atherosclerotic plaques the morphological and biological aspects of these plaques with MRI and 18F-FDG-PET imaging. Methods. Carotid arteries were imaged 150 minutes after injection of 18F-FDG with a combined PET/MRI system. American Heart Association (AHA) lesion type and plaque composition were determined on consecutive MR axial sections (n = 460) in both carotid arteries. 18F-FDG uptake in carotid arteries was quantified using tissue-to-background ratio (TBR) on corresponding PET sections. Results. Prevalence of complicated atherosclerotic plaques (AHA lesion type VI) detected with high-resolution MRI was significantly higher in the carotid artery ipsilateral to the ischemic stroke as compared to the contralateral side (39% vs. 0 %; $p = 0.001$). For all other AHA lesion types, no significant differences were found between ipsilateral and contralateral sides. In addition, atherosclerotic plaques classified as high-risk lesions with MRI (AHA lesion type VI) were associated with higher 18F-FDG uptake in comparison with other AHA lesions (TBR = 3.43 ± 1.13 vs. 2.41 ± 0.84; respectively; $p < 0.001$). Furthermore, patients presenting at least one complicated lesion (AHA lesion type VI) with MRI showed significantly higher 18F-FDG uptake in both carotid arteries (ipsilateral and contralateral to the stroke) in comparison with carotid arteries of patients showing no complicated lesion with MRI (mean TBR = 3.18 ± 1.26 and 2.80 ± 0.94 vs. 2.19 ± 0.57; $p < 0.05$, respectively), in favor of the presence of a diffuse inflammatory process along both carotid arteries associated with complicated plaques. Conclusions. Morphological and biological features of high-risk plaques can be detected with high-resolution MRI and 18F-FDG-PET in non-stenotic atherosclerotic plaques ipsilateral to the stroke, suggesting a causal role for these plaques in stroke. Combined 18F-FDG-PET-MRI systems might help in the evaluation of patients with ischemic stroke classified as cryptogenic.

OP472
Atherosclerotic Plaque 18F-NaF Uptake Predicts its Subsequent Morphologic Evolution and Calcification Density

F. Fiz[1], M. Bauckneht[1], G. Ferrarazzo[1], A. Piccardo[2], E. Pestarino[2], I. Calamia[1], M. Cabria[2], G. Villavecchia[2], C. Marini[3], S. Morbelli[1], G. Sambuceti[1]; [1]Nuclear Medicine Unit, Department of Health Sciences, University of Genoa, Genoa, ITALY, [2]Nuclear Medicine Unit, Ente Ospedaliero Galliera, Genoa, ITALY, [3]CNR-IBFM, Milano, ITALY

Background and Aims: Evaluation of calcium deposition within arterial calcifications (AC) can be performed using 18F-NaF PET/CT; our previous experience demonstrated that AC density at CT inversely correlates with its 18F-NaF uptake. We planned the present study to investigate whether a higher tracer uptake, by signaling an active calcium deposition, predicts a subsequent AC evolution. Patients and Methods: We retrospectively included 50 patients (18 women, mean age 68±9 years, age range 41-86) who underwent at least two consecutive 18F-NaF PET/CT in the course of follow-up of bone metastases from breast or prostate cancer. Only scan spaced at least one year and at most two years were included. In each scan we drew a volume-of-interest (VOI) on each AC within the infrarenal aorta walls and we calculated its average Hounsfield density (HU), its blood-pool normalized average uptake (target-to-background ratio, TBR, obtained by

normalizing AC SUVmean with the one of a 10-slice-thick VOI, drawn within the inferior vena cava) and its Calcification Score (CS, using an Agaston-like algorithm). We stratified all AC in tertiles according to their baseline TBR in "cold" (lower tertile, CP), "warm" (middle tertile, WP) and "hot" (higher tertile, HP) plaques. We then calculated, on each consecutive scan and on a plaque-by-plaque basis the percent difference in mean HU e CS (defined as DHU% and DCS%, respectively). Results: 430 AC were identified. In CP there wasn't any significant increase neither in HU nor in CS at subsequent scans. Conversely, both parameters significantly increased in WP and HP ($p<0.01$ and $p<0.001$, respectively). Mean DHU% was progressively increasing from CP to HP (11±9%, 36±16% and 67±32%, $p<0.01$ for CP vs. WP and $p<0.05$ for WP vs. HP); average DCS% showed a similar pattern ($p<0.05$). As a consequence, there was a positive correlation between TBR and both DHU% ($R=0.75$, $p<0.01$) and DCS% ($R=0.69$, $p<0.01$). Conclusion: 18F-NaF uptake within the atherosclerotic plaque, by tracing mineral turnover, can be used as a hallmark of calcium deposition and can therefore predict whether any given plaque will subsequently evolve in size and density.

OP473

18F-FDG-PET-CT assessed subclinical arterial inflammation is positively associated with non-invasive markers of arterial stiffness in recently diagnosed type 2 diabetes patients

S. A. de Boer[1], M. C. Hovinga - de Boer[2], J. D. Lefrandt[1], H. J. Lambers Heerspink[3], A. W. J. M. Glaudemans[4], D. J. Mulder[1], R. H. J. A. Slart[4,5]; [1]Department of Vascular Medicine, University Medical Center Groningen, University of Groningen, Groningen, NETHERLANDS, [2]Department of Radiology & Nucleair Medicine, Meander Medical Center, Amersfoort, NETHERLANDS, [3]Department of Clinical Pharmacy and Pharmacology, University Medical Center Groningen, University of Groningen, Groningen, NETHERLANDS, [4]Department of Nucleair Medicine and Moleculair Imaging, University Medical Center Groningen, University of Groningen, Groningen, NETHERLANDS, [5]Universtity of Twente, Department of Biomedical Photoacustic Imaging (BMPI), Enschede, NETHERLANDS

Aim: Type 2 diabetes mellitus (T2DM) is accompanied by premature arterial stiffness. The underlying mechanisms are unclear. We investigated the possible relation between subclinical arterial inflammation, calcification, atherosclerotic risk factors, skin advanced glycation end products (AGEs)), and arterial stiffness in T2DM. Materials & methods: 34 patients with recently diagnosed T2DM (RELEASE study: NCT02015299), without a history of cardiovascular disease and not using glucose lowering drugs, were studied (age 63 (55-66) yrs, 65% male, HbA1c 46 ±4.3 mmol/mol (6.4±0.4%), 18% smokers). Arterial stiffness was non-invasively assessed by aortic systolic blood pressure (aSBP, mmHg) and aortic (carotid-femoral) pulse wave velocity (aPWV) using applanation tonometry. A whole body 18-Fluorodeoxyglucose positron emission tomography-(low dose) computed tomography (^{18}F-FDG-PET-CT) scan was performed to assess arterial inflammation (standard uptake value (SUV)max (according to EARL guidelines)) and CT-scored arterial calcification (AC): visual score: 0 (no) to 4(>50% calcified plaque). SUVmax and AC scores were calculated in 4 individual segments (carotid arteries, ascending aorta and aortic arch, descending and abdominal aorta, and iliac and femoral arteries) and for the total aortic tree (aSUVmax, mean of 4 segments). Skin AGEs were measured as skin autofluorescence (SAF). Results and conclusion: aSUVmax and AC were not associated. aSUVmax was associated with atherosclerotic risk factors: BMI ($r=0.64$, $P<0.001$), HbA_{1c} ($r=0.59$, $P<0.001$), waist circumference ($r=0.55$, $P<0.001$) but not with, age, gender, smoking, lipids, and SAF. aSUVmax was associated with non-invasive markers of arterial stiffness: aSBP ($r=0.55$, $P=0.001$) and tended to correlate with aPWV ($r=0.33$, $P=0.059$). After multivariate adjustment ($r^2=0.79$, $P<0.001$), only HbA_{1c}, ($\beta=0.36$, $P<0.001$), waist circumference ($\beta=0.49$, $P<0.001$), aSBP ($\beta=0.49$, $P<0.001$), and aPWV ($\beta=0.24$, $P=0.014$) remained significant. AC was associated with male gender ($r=0.48$, $P=0.004$), age ($r=0.51$, $P=0.002$), BMI ($r=-0.43$, $P=0.011$), and SAF ($r=0.37$, $P=0.036$) and not with other mentioned atherosclerotic risk factors. None of AC scores correlated with aPWV, aSBP, or any of the SUVmax segments. After multivariate adjustment ($r^2=0.39$, $P=0.001$) only male gender ($\beta=0.49$, $P=0.003$) and SAF ($\beta=0.34$, $P=0.033$) remained significant. These results show that in recently diagnosed T2DM patients 18F-FDG-PET-CT revealed subclinical arterial inflammation but not calcification, and is positively associated with determinants of arterial stiffness, glycemic control and central obesity. Interessingly, while the extent of arterial calcification did not show any relation with arterial inflammation, it was independently associated with skin AGEs, suggesting discordant pathways at different stages of atherosclerotic disease.

OP474

Evaluation of the radiotracer [68Ga]pentixafor targeting the CXCR4 receptor with PET-MRI in a rabbit model of atherosclerotic plaques

F. Hyafil[1], I. Laitinen[1], M. Schottelius[2], M. Mohring[1], A. Poschenrieder[2], J. Brandl[3], C. Baumgartner[3], J. Pelisek[4], S. Nekolla[1], H. Wester[5], M. Munich, GERMANY, [5]Pharmaceutical Radiochemistry, Technische Universität München, Munich, GERMANY

Introduction: The CXCR4 receptor is expressed at the surface of lymphocytes, macrophages and neutrophils. [68Ga]Pentixafor is a PET radiotracer that binds with a nanomolar affinity to the CXCR4 receptor. The aim of this study was to test whether [68Ga]Pentixafor binds specifically to CXCR4-expressing tissues and allows for the detection of inflamed atherosclerotic plaques induced in rabbits. Methods: Atherosclerotic plaques were induced by endothelial abrasion of the right carotid artery and abdominal aorta of 7 New Zealand White rabbits fed an atherogenic diet. Three non injured rabbits fed a chow diet were used as controls. Rabbits were imaged on a combined PET-MRI system 1 hour after injection of 15 MBq/kg of [68Ga]Pentixafor. Tissue to background ratios (TBRs) were measured with PET-MRI along carotid arteries and in the abdominal aorta. After PET-imaging, biodistribution studies were performed one hour after injection of 7.5 MBq/kg of [125I]Pentixafor. Tracer uptake was quantified on 20 μm cryosections of arteries using autoradiography and normalized to muscle uptake. In addition, blocking studies were performed in two atherosclerotic rabbits with pre-injection of 2 mg of the CXCR4 inhibitor AMD3100. Results: Biodistribution studies showed significantly higher accumulation of [125I]Pentixafor in CXCR4-expressing tissues such as spleen (0.19 ± 0.07 % ID / g), adrenal glands (0.30 ± 0.13 % ID/g) and bone marrow (0.16 ± 0.06 % ID/g), than in other tissues such as muscle (0.02 ± 0.01 % ID/g) or heart (0.02 ± 0.01 % ID/g). [125I]Pentixafor binding in CXCR4-expressing tissues was strongly decreased after injection of the CXCR4 inhibitor AMD 3100. One hour after injection of [68Ga]pentixafor, a clear signal was detected in vivo with PET-MRI in atherosclerotic plaques of the abdominal aorta and right carotid artery as compared to normal control arteries (average TBR = 1.95 ± 0.51 vs. 1.22 ± 0.25 and TBR = 1.24 ± 0.38 vs. 0.96 ± 0.37 ; $p < 0.05$ for both). Consistently, higher tracer uptake was measured by autoradiography in cryosections of atherosclerotic plaques as compared to normal arteries. Conclusions: [68Ga]Pentixafor accumulates specifically in CXCR4-expressing tissues in rabbits. [68Ga]Pentixafor uptake was increased in inflamed atherosclerotic plaques compared to normal arteries. Hence, [68Ga]Pentixafor might emerge as a valuable tool for the detection of high-risk atherosclerotic plaques with PET.

OP475

Targeting Aminopeptidase N (CD13) for molecular imaging of cardiac wound healing using ^{68}Ga-NOTA-c(NGR) in experimental myocardial infarction

S. Samnick[1], M. Schneider[1], J. Tillmanns[2], D. Fraccarollo[2], J. Bauersachs[2], A. Buck[1]; [1]University of Wuerzburg, Wuerzburg, GERMANY, [2]Hannover Medical School, Hannover, GERMANY

Purpose: Aminopeptidase N (CD13) is a transmembrane protease involved in cell adhesion, migration, proliferation, differentiation and angiogenesis. In myocardium, CD13 is overexpressed in athophysiologic conditions such as acute myocardial infarction (MI), where it facilitates inflammatory cell infiltration. After MI, the wound healing phase is important for successful tissue repair and improved remodeling. Molecular imaging could help to understand activity and duration of the repair processes in individual patients, and potentially allows patient-specific administration of pharmacotherapy to improve outcome after MI. On the other hand, peptides containing the NGR (Asparagine-Glycine-Arginine) motif bind selectively to CD13. This study investigates the potential of the radiolabeled NGR-containing tracer ^{68}Ga-NOTA-NGR as an imaging probe for in vivo assessment of the early wound healing phase after MI using PET. Methods: Myocardial ischemia/reperfusion injury (MI/R) was induced in rats, and the uptake of the novel ^{68}Ga-labelled NGR peptide (^{68}Ga-NOTA-NGR) was evaluated in comparison with ^{68}Ga-NOTA-RGD and ^{18}F-FDG at day 3, 7 and 21 post infarction using μ-PET and autoradiography. Expression of CD13, the molecular target of NGR, and $\alpha_v\beta_3$, the molecular target of RGD, were assessed in fibroblasts, inflammatory cells and endothelial cells in rat hearts by immunohistochemistry, and correlated with radiotracer uptake. Results: Infarcted and surviving myocardium was identified by ^{18}F-FDG-PET in all animals. In the infarcted myocardium, uptake of ^{68}Ga-NOTA-NGR was maximal from day 3 to 7 after MI/R, and correlated with fibroblast and inflammatory cell infiltration as well as ^{68}Ga-NOTA-RGD uptake. Conclusions: This study demonstrates for the first time the feasibility of PET with ^{68}Ga-NOTA-NGR for noninvasive and sequential determination of CD13 expression in rat heart after MI/R. This will facilitate monitoring of CD13 in the individual wound healing processes, allowing patient-specific therapies to improve outcome after MI.

OP476

Retrospective detection of remote and brief experimental myocardial ischemia using 99mTc-Fucoidan SPECT

N. Mikail[1], N. Anizan[2], L. Louedec[2], F. Al Shoukr[1], J. Michel[2], D. Letourneur[2], C. Chauvierre[2], D. LE GULUDEC[1], F. Rouzet[1]; [1]Nuclear Medicine Department, Bichat-Claude Bernard Hospital, APHP, Paris, FRANCE, [2]INSERM, U1148, Cardiovascular Bioengineering, Paris, FRANCE

Aim: the retrospective identification of a remote acute coronary syndrome is a diagnostic challenge. Because adhesion molecules such as selectins persist on the endothelial surface after ischemia has resolved, they represent a tissue “imprint” of the prior ischemic event, referred to as ischemic memory. The aim of this study was to assess whether 99mTc-fucoidan

SPECT, a P-and E-selectin targeting agent, allows to detect myocardial ischemic memory in a rat model of ischemia-reperfusion. Methods: Transient myocardial ischemia was induced in male Wistar rats by coronary ligation. Ischemia duration ranged from 5 min to 20 min and reperfusion duration ranged from 2 to 24 hours. SPECT/CT acquisitions were performed 2 hours after injection of 70 MBq 99mTc-Fucoidan. Images were visually assessed for the presence of a focal tracer uptake in the cardiac area. The animals were then sacrificed and the heart explanted, frozen and cut in slices for autoradiography (quantified using the uptake ratio between the area at risk and remote myocardium) and histology/immunostaining (P-/E-selectin expression). Results: For a constant delay of 2 hours of reperfusion, myocardial uptake of 99mTc-Fucoidan was detected after ischemia duration ranging from 20 minutes (3/3 rats), 10 minutes (3/4 rats) and 5 minutes (5/14 rats). On autoradiography, the uptake ratio of 99mTc-Fucoidan was 7.6 [4.6-8.4] at 20 min, 5.6 [3.8-12.1] at 10 min and 4.6 [2.0-8.2] at 5 min. Areas of 99mTc-Fucoidan increased uptake matched with endothelial expression of P-selectin. After 6 hours of reperfusion duration, the 99mTc-Fucoidan uptake was detected in 4/4 rats (10 min ischemia) and 3/5 rats (5 min ischemia). After 24 hours of reperfusion duration, 99mTc-Fucoidan uptake was detected in 3/7 rats (10 min ischemia) and 4/9 rats (5 min ischemia). Conclusion: This preliminary study shows that brief coronary occlusions (5 minutes) followed by reperfusion durations up to 24 hours are associated with P- and E-selectin endothelial expression, detectable in vivo by 99mTc-Fucoidan SPECT. Therefore, 99mTc-Fucoidan is a promising agent that could be useful in the retrospective diagnosis of acute coronary syndromes.

Preparation of Carrier Free Yttrium-90 for Medical Applications Using a Novel Home-Made Y-Imprinted Sorbent

M. Abedi[1], **S. Shirvani Arani**[2], A. Bahrami Samani[3], M. Nabid[1]; [1]Department of Chemistry, Faculty of Science, Shahid Beheshti University, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Assistant Professor Radiopharmaceutical Research and Development Lab (RRDL), Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]Radiopharmaceutical Research and Development Lab (RRDL), Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim: Synthesis and characterization of a novel acryl amide-based yttrium imprinted sorbent via the ATRP approach for the preparation of medical-grade 90Y. Materials and methods: 2,2-bis(2-bromo-2-methylpropanoate)propane-1,3-disuccinate (L), which was synthesized in three steps in our lab, was used as an excellent chelating agent and also as an initiator for the preparation of a novel acryl amide-based ion imprinted polymer (IIP) for selective sorption of radio-yttrium. The YIP was prepared via copolymerization of the (Y- L) complex with acryl amide as the functional monomer and N,N'-methylenebisacrylamide as a crosslinking agent using the ATRP approach. The synthesized compounds were characterized, and sorption/desorption examination was performed. The prepared Y-IIP was used as a sorbent for the selective separation of 90Y from a synthetic solution of 90Y/Sr(natural, stable)/Zr(natural, stable). To the best of our knowledge, this was the first ionic-imprinted sorbent used to prepare carrier free 90Y. Results: The data confirmed the perfect separation of Sr(II) and Zr(II) from 90Y, which was maintained successfully on the column and eluted afterwards. As a result, the prepared, highly yttrium-selective sorbent can be used for the separation of Y-90 from its long-lived parent, Sr-90. In addition, if there are any other impurities even in trace amounts, such as Zr(II) that is a decay product of Y-90, they can be removed effectively to prepare medical grade 90Y from a long-lived 90Sr source via the least facility. Conclusion: In this study, a new acryl amide-based sorbent was synthesized in order to prepare medical-grade 90-yttrium. The synthesis was conducted through atom transfer radical copolymerization of AAm and MBAAm in the presence of BMPPS as the initiator and chelator for Y(III) ion that is capable of extracting and preconcentrating traces of Y(III) ion. The effective parameters of the yttrium (III) preconcentration were investigated. Due to the high selectivity obtained by the aforementioned, new, acryl amide-based sorbent, it can be used effectively for the selective separation and pre-concentration of yttrium (III). In future studies, we plan to utilize the prepared sorbent to fabricate a set of serial columns for the preparation of a 90Sr/90Y column chromatographic generator to obtain carrier-free 90Y. The freshly eluted radionuclide then can be used for radiolabeling of the peptides and antibodies that are used in targeted therapy for various types of cancers and solid tumors.

OP478

Cyclotron production of 43Sc - new radionuclide for PET technique

A. Bilewicz[1], R. Walczak[2], K. Szkliniarz[3], M. Sitarz[4], S. Krajewski[2], K. Abbas[5], J. Choinski[4], I. Cydzik[5], A. Jakubowski[4], J. Jastrzębski[4], A. Stolarz[4], A. Trzcińska[4], W. Zipper[3]; [1]Institute of Nuclear Chemistry and Technology, WArsaw, POLAND, [2]Institute of Nuclear Chemistry and Technology, Warsaw, POLAND, [3]Department of Nuclear Physics, University of Silesia, Katowice, Poland, Katowice, POLAND, [4]Heavy Ion Laboratory, University of Warsaw, Warsaw, POLAND, [5]European Commission, Joint Research Centre, Institute for Health and Consumer Protection, Ispra, ITALY

Aim: The ^{43}Sc ($t_{1/2}$ = 3.89 h) is an ideal β^+-emitter in PET diagnosis. It can be used as an alternative to ^{68}Ga, because ^{43}Sc has longer half-life and forms stable radiobioconjugates with a structure similar to ^{90}Y and ^{177}Lu, that is important in planning radionuclide therapy. In comparison with ^{44}Sc -other proposed isotope of scandium - ^{43}Sc has half-life and beta plus radiation similar to ^{44}Sc, moreover gamma-ray energy emission and intensity is much lower (372 keV, 23%) than in case of ^{44}Sc (1157 keV, 99%) what is not negligible for patient and medical personnel. ^{43}Sc can be produced via the $^{nat}Ca(\alpha,x)^{43}Sc$ reaction in medium size cyclotrons or in reactions $^{43}Ca(p,n)^{43}Sc$ and $^{42}Ca(d,n)^{43}Sc$ carried in small medical cyclotrons. The aim of our work was to find optimal parameters for target irradiations in order to maximize the production of ^{43}Sc with minimal impurities and to develop a simple chemical procedure for separation of ^{44}Sc from the calcium target. Materials and methods: In the present work, we used either high purity natural $CaCO_3$ or enriched $^{42}CaCO_3$ and $^{43}CaCO_3$ targets (Isoflex, Russia). The irradiations have been performed with the Scanditronix MC 40 Cyclotron of the Joint Research Centre (Ispra, Italy), or U-200P and GE-PETtrace cyclotrons of the Heavy Ion Laboratory, University of Warsaw. Target materials for irradiation were compacted into the specially designed aluminum capsules or were pressed into a rectangular pellet wrapped in the pre-formed aluminum foil and fixed to a water cooled target holders. The activities of the samples were measured with high resolution γ-ray spectrometry. $CaCO_3$ targets were dissolved in 0.2 M HCl and an ion exchange resin Chelex 100 was used to separate ^{43}Sc from target material.^{43}Sc-DOTATATE was synthesised with different amounts of the peptide and at various pH. Results: The three proposed methods of ^{43}Sc production allow obtaining the high activity of the radionuclide. ^{43}Sc was separated from the targets on iminodiacetic resin with efficiency higher than 95% and eluted in volume of 0.3 ml. The recovery of the calcium material is also very high (~90 %). The level of Ca^{2+} in ^{43}Sc fraction is less than 3 μg/ml. Conclusions: The ^{43}Sc radionuclide can be produced in amount of several GBq. The proposed production procedures are simple and fast. The synthesis and purification procedure can be simplified using C18 Sep-Pak® columns.

OP479

Production of High Specific Activity 186Re for Cancer Therapy Using WO3 Targets in a Proton Beam

M. E. Fassbender[1], E. R. Birnbaum[1], J. W. Engle[1], M. D. Gott[2], K. D. John[1], J. R. Maassen[1], F. M. Nortier[1], J. W. Lenz[3], C. S. Cutler[4], A. R. Ketring[4], S. S. Jurisson[4], E. R. Balkin[5], D. S. W. Wilbur[5]; [1]Los Alamos National Laboratory, Los Alamos, NM, UNITED STATES, [2]University of Missouri, Columbia, MO, UNITED STATES, [3]John Lenz and Associates, East Lansing, MI, UNITED STATES, [4]Univeristy of Missouri, Columbia, MO, UNITED STATES, [5]Univeristy of Washington, Seattle, WA, UNITED STATES

Rhenium-186 is a β-γ emitter with a half-life of 90.64 h and a $\beta-$ end-point energy of 1.07 MeV. The isotope is suitable to treat cancers of small dimensions (mm range). Moreover, its γ-emission at 137.15 keV is in the energy range favorable for both γ-camera and SPECT imaging. Current production methods rely on the neutron capture induced reaction 185Re(n,γ) in a reactor and are associated with low specific activities (0.6 kCi/mmol), thereby limiting the application of the isotope to palliative treatments. Production via charged particle irradiation of enriched 186W results in a 186Re product with a much higher specific activity; allowing its use in therapeutic nuclear medicine. Test targets of both sintered and pressed natWO3 powder were proton irradiated at the Los Alamos Isotope Production Facility (LANL-IPF) to evaluate radionuclide product yields, impurities, irradiation parameters and wet chemical Re recovery for a bulk production. We demonstrated that 186gRe can be isolated in 97% yield from irradiated natWO3 targets within 12 h of end of bombardment (EOB) via an alkaline dissolution followed by anion exchange. Tungsten (VI) oxide can be easily recycled for recurrent irradiations. Using a sintered target, 186Re batch yields of 42.7 +/- 2.2 μCi/μAh (439 +/- 23 MBq/C) (with respect to 186W content) were obtained after 24 h of irradiation in proton beams. The target entrance energy of the proton beam was determined to be 15.6 MeV. The specific activity of 186gRe at EOB was measured to be 1.9 kCi (70.3 TBq)/mmol. Based upon our studies of natWO3, a target of enriched 186WO3 irradiated in a proton beam of 250 μA for 24h can provide batch volumes of roughly 250 mCi (9.25 GBq) of 186gRe at EOB with a specific activity approaching the theoretical value of 35kCi/mmol (1295 TBq/mmol).

OP480

Direct production of 99mTc-Technetium using low energy cyclotrons and radionuclidic purity: our results so far using natMo-Molybdenum

L. Metello[1,2], P. Costa[1], L. Cunha[1,2], R. Jonhson[3], L. Matei[3], W. Gelbart[4], J. Obermair[5], C. Artner[5], P. Lass[6], G. Currie[7], L. Craciun[8], D. Niculae[8], S. Carmo[9], F. Alves[9], M. Botello[10]; [1]Nuclear Medicine Department, ESTSP.IPP, Porto, PORTUGAL, [2]Nuclear Medicine Department, IsoPor SA, Porto, PORTUGAL, [3]BSCI - Best Cyclotron Systems Inc, Vancouver, DC, CANADA, [4]ASD - Advanced Systems Design Inc, Vancouver, DC, CANADA, [5]IASON GmbH, Graz, AUSTRIA, [6]Medical Faculty, University of Gdansk, Gdansk, POLAND, [7]School of Dentistry and Health Sciences, Charles Sturt University, Wagga Wagga, AUSTRALIA, [8]Horia Hulubei National Institute of Physics & Nuclear Engineering, Bucarest, ROMANIA, [9]ICNAS - Institute for Nuclear Sciences Applied to Health, University of Coimbra, Coimbra, PORTUGAL, [10]IBILI, Medical Faculty, University of Coimbra, Coimbra, PORTUGAL

Introduction: Despite the global crisis concerning 99mTc delivering to Nuclear Medicine Departments there isn't yet a reliable solution. The cyclotron direct production of 99mTc, using the 100Mo(p,2n)99mTc nuclear reaction is our attempt to approach the problem, aiming to become efficient, reliable and sustainable from points of view as reducing drastically the radioactive waste being produced and becoming beneficial for all the involved parts. Between several critical factors, radionuclidic purity of cyclotron-produced 99mTc is being pointed as an issue of concern. Aim: This paper aims to disseminate the results being obtained so far in what concerns radionuclidic purity of the 99mTc already produced from natMo and some extrapolation calculi for the use of high-level of purity 100Mo. Material and Methods: natMo foils were stacked into a solid target of aluminum and short irradiations (with ~1-2 to 20 μA proton beams, during 2 to 20 seconds) were performed, using our in-house developed targets and target holder systems, on three different cyclotrons (IBA Cyclone-18, ACSI TR19 and GE PETtrace). Beam energy degraders based on aluminum were developed in-house with thicknesses calculated using SRIM/TRIM, allowing irradiations with 15 MeV in the IBA and GE machines. Produced activity was quantified using HPGe gamma spectroscopy to obtain the overall amount of 99mTc produced, as well as the different contaminants (such as 93Tc, 93mTc, 94Tc, 94mTc, 95Tc, 95mTc, 96Tc, 96mTc, 99Mo and 96Nb) whose activity was analyzed in terms of ratios in order to 99mTc activity. Novel ratios were extrapolated from our experimental data to an ideal case of irradiations using 100Mo enriched targets (with purities of 97,42% and 99,5%). Results: It has been observed, that 19 and 18 MeV irradiations of natMo lead to an higher level of contaminants, with produced yields of some contaminants much higher than those of 99mTc being produced (e.g.: 93Tc, 94Tc and 95Tc), however, extrapolated contaminant ratios for enriched targets suffer a reduction, even considering values deserving attention (e.g.: 94Tc/99mTc ≥ 1% or 93Tc/99mTc ≥ 3%). On other hand, our results confirm our hypothesis that 15 MeV irradiations could maintain considerable production yields, with a significant decrease of contaminants, with almost all extrapolated ratios reaching values ≤ 1%. Conclusion: Radionuclidic purity is a critical issue for the implementation of alternative routes for 99mTc production and our actual data points that 15 MeV proton beams could be considered, since drastically reducing contaminants while easing production and purification processes.

OP481

Extremely rapid, kit-based biomolecule labelling and molecular imaging with gallium-68: tris(hydroxypyridinone) chelators

M. T. Ma[1], J. D. Young[1], C. Imberti[1], C. Cullinane[2], M. S. Cooper[1], L. Meszaros[1], S. Y. A. Terry[1], B. Paterson[1], G. E. D. Mullen[1], J. R. Ballinger[1], P. Roselt[2], R. J. Hicks[2], P. J. Blower[1]; [1]King's College London, London, UNITED KINGDOM, [2]Peter MacCallum Cancer Centre, Melbourne, AUSTRALIA

The gallium-68 (68Ga) generator offers PET molecular imaging to hospitals without a cyclotron if simple labelling methods are devised. Current 68Ga clinical radiopharmaceutical syntheses require high temperatures (greater than 90 °C), and extended reaction times (5 - 20 min). We have previously shown that tris(hydroxypyridinone) (THP) ligands rapidly label with 68Ga quantitatively under mild conditions (Chem Commun, 2011; 47:7068). We now report the development of one-step labelling methods equivalent to kit formulation protocols, and the ability of 68Ga-THP peptide conjugates to image expression of peptide receptors in tumours in vivo. The THP-Ac chelator was labelled with 68Ga-generator eluate under a range of THP-Ac concentrations (0.1-1000 μM), pH values (4 - 7), buffers, and trace metal concentrations (Mg(II), Fe(III), Zn(II)). At 10 μM, 20 °C and all pH values and times, labelling efficiency of THP-Ac reached greater than 95% in under 2 min, and was unaffected by contaminating Mg(II), Zn(II) and Fe(III) at 30, 20, 0.3 mg/L, respectively. Vials containing lyophilised THP-Ac and buffer salts gave quantitative radiolabelling with unprocessed eluate in less than 5 min. New bifunctional chelator isothiocyanate and carboxylate derivatives of THP were synthesised and conjugated to (i) cyclic(RGDfK) peptides for targeting αvβ3 integrin expression, (ii) Tyr3-octreotate (TATE) peptide for targeting SSTR2 expression in neuroendocrine tumours, (iii) a urea-containing peptide targeting PSMA receptors for prostate tumours, and (iv) the monoclonal antibody, trastuzumab for HER2 receptors. All conjugates were labelled with 68Ga in greater than 95% radiochemical yield and high specific activity (up to 80 MBq/nmol at the point of administration) at 25 °C and formulated to pH 6 - 7 in 2 - 5 min. Biodistribution of tested αvβ3- and SSTR-targeting conjugates showed tumour-specific uptake and retention of target receptor affinity. Excretion was rapid and predominantly renal. Serum stability and biodistribution experiments point to excellent in vivo stability of the new radiotracers with respect to the 68Ga-THP complex. Notably, in vivo tumour uptake and biodistribution of 68Ga-THP-TATE was comparable to that of the clinical radiopharmaceutical, 68Ga-DOTA-TATE.The new tris(hydroxypyridinone) chelator and its conjugates enable

rapid radiolabelling with 68Ga under mild conditions without subsequent purification. The simplicity of radiochemical syntheses based on such conjugates is conducive to translation to one-step kit-based radiosyntheses that would greatly facilitate the expansion and adoption of 68Ga PET in hospitals.

OP482

Microfluidics and Microwave Assisted Synthesis of 99mTc(CO)3-MIP-1505, a ligand for carbonic anhydrase IX (CAIX). Comparison to Conventional Heating

J. Kelly, A. Amor-Coarasa, J. W. Babich; Weill Cornell Medical College, New York, NY, UNITED STATES

AIM: To compare the formation of a $^{99m}Tc(CO)_3$ complex and the subsequent labeling of **MIP-1505**, a ligand for carbonic anhydrase IX, using a microfluidics system, a microwave reactor, and a conventional heating block. METHODS: The microfluidics labeling experiments were undertaken on a NanoTek LF system (Advion) with the reactor coil heated to 150°C. A 150 μg/mL solution of MIP-1505 in DMSO and a 3.7 GBq/mL solution of $^{99m}TcO_4^-$ in saline containing 6 mg $CH_3BNa_2O_2$, 2.9 mg $Na_2B_4O_7.10H_2O$, 8.5 mg $C_4H_4Na_2O_6.2H_2O$, 7.2 mg Na_2CO_3 ("Isolink kit") were passed through the reactor at a maximum combined flow rate of 30 μL/min. Reaction times varied from 1-3 minutes according to stoichiometry and flow rates. Labeling in the microwave reactor (Biotage) was undertaken at 100°C, 125°C, and 150°C. Formation kinetics of the $^{99m}Tc(CO)_3$ complex were evaluated in the absence of MIP-1505. A solution of 50 μg MIP-1505 in 0.5 mL saline was added to the tricarbonyl kit, and the reaction was heated for up to 20 minutes. Synthesis of $^{99m}Tc(CO)_3$-MIP-1505 on a heating block (ThermoFisher) was undertaken over 60 min at 100°C[1].RESULTSIn 1 minute, 3 μg MIP-1505 was labeled in 91.2±0.6% yield in the microfluidics system. When reaction time was 2 minutes, 2.2 μg MIP-1505 was labeled in a similar yield. In both cases, 6-8% of the unbound ^{99m}Tc was in the form of the $^{99m}Tc(CO)_3$ complex. Rapid and nearly quantitative tricarbonyl formation was observed after 1 minute of microwave heating at 125°C (98.9±0.16%) and 150°C (99.9±0.2%), and after 2 minutes at 100°C (98.5±0.46%). Labeling of MIP-1505 was most rapid at 150°C, reaching 58.5±4.1% after 5 minutes. At 125°C the maximum labeling was 67.6±0.4% (10 minutes), while at 100°C the labeling was 51.1±3.4% (20 minutes). By conventional heating, the labeling of MIP-1505 was 63±12% after 60 minutes. CONCLUSIONS: Synthesis by microfluidics provides $^{99m}Tc(CO)_3$-MIP-1505 in high specific activity and with the greatest yield, though there is no time advantage relative to microwave heating when a clinical dose (<185 MBq) is produced. Both microwave heating and microfluidics are significantly faster than conventional heating with no significant difference in labeling yield. This is advantageous in the planning of pre-clinical and/or clinical studies. Economy of time and reagents makes microfluidics an attractive approach for the production of $^{99m}Tc(CO)_3$-MIP-1505 for pre-clinical studies, while microwave heating appears to be the most promising route to a clinical dose.[1] Lu, et al. J. Med. Chem. 2013, 56, 510-520.

OP483

Microfluidics Assisted Labeling of 68Ga-DOTATOC: Advantages and Limitations.

A. Amor-Coarasa, J. M. Kelly, J. W. Babich; Weill Cornell Medical College, New York City, NY, UNITED STATES

Aim: To maximize 68Ga-DOTATOC specific activity (SA) and minimize reaction time by using microfluidics (MFs) assisted chelation chemistry. Materials and Methods: Gallium-68 (68Ga) was obtained by eluting with 4 ml 0.05M HCl a 1.85 GBq (50 mCi, at calibration) itG 68Ge/68Ga Generator. Labeling was performed in a NanoTek Microfluidic Flow-Chemistry System (Advion, USA). The eluate was buffered with 120 μl of 3N NaOAc (pH 4-5). DOTATOC was prepared as a 100 μg/ml solution in the same buffer. The effect of stoichiometry and temperature (95 or 150 °C) was studied. Labeling was also performed in a conventional heater (CH) for comparison. Radio-HPLC was used to determine radiochemical yield (RCY) and purity. Results: The RCY of 68Ga-DOTATOC using MFs was nearly 70% (68.3±2.4%) at 150°C as compared to 46.5±4.4% at 95°C. RCY was not significantly dependent on DOTATOC mass within the 60 ng (42.2 pmol) to 150 ng (105 pmol) range. At 95°C, MFs labeling of DOTATOC varied from 41.6±6.5% (60 ng) to 50.7 ±3.5% (150 ng). The variation was similarly low at 150°C, with RCYs of 65.7±2.1% (60 ng) and 70.3±1.8% (150 ng). When the mass of DOTATOC was decreased to 15 ng, labeling yields decreased to 3.2±0.7% at 150°C and no labeling was observed at 95°C. Despite the high labeling yields (≈70% with 100 ng of DOTATOC at 150°C vs. <1% with CH at 95°C) obtained in 1 minute with the microfluidics system, the critical parameter for radiopharmaceutical production is radionuclide concentration. The maximum activity that can be produced in one minute using the buffered generator elution is 25.9 MBq (0.7 mCi), such that over 7 minutes are necessary to produce a patient dose of 185 MBq (5 mCi). During this time greater dose (lower SA) can be produced with CH. Use of 68Ga pre-concentration systems[1] allows the same patient

dose in 3 min, however increased manipulation is needed. In contrast preclinical doses can be obtained within seconds. Conclusion: Microfluidics assisted reactions have great potential for preparation of high specific activity products minimizing precursor degradation at high temperatures. It shows clear advantages for discovery applications and preclinical testing. However clinical application is severely limited by low activity/time production and high equipment costs. High potential for flow interruption also reduces its reliability for everyday radiopharmaceutical production in a clinical setting. A Fast Optical Method for Radiochemical Purity Evaluation

A. E. Spinelli[1], C. R. Gigliotti[1], F. Boschi[2]; [1]San Raffaele Scientific Institute, Milano, ITALY, [2]University of Verona, Verona, ITALY

Aim: The standard technique to evaluate the radiochemical purity (RCP) is the thin-layer chromatography. RCP is an important index for the radiopharmaceutical QA because identify the percent of the total radioactivity present in the desired chemical form in a radiopharmaceutical. This value is commonly obtained from the activity distribution measured with a conventional radiation detector along the chromatographic strip (CS). We propose here an alternative CCD-based approach to quickly image the CSs.Methods: We use a system composed of cooled electron multiplied charge coupled device (EMCCD) coupled with lens mounted on a light-tight box and a high-resolution intensifying screen for radiation conversion. CSs with 7 kBq of 68Ga-DOTANOC and 5 kBq of 99mTc-HMDP were imaged. A photographic image is acquired and then the samples are covered with the screen. The emissive signal is acquired for 10s. In order to validate our approach, the same strips were imaged with the Cyclone Plus Storage Phosphor system (Perkin-Elmer) based on a conventional PSP, routinely used to analyse CSs.Results and conclusion: From the activity profile evaluated along the signal of the 68Ga-DOTANOC acquired with the commercial system and with our optical system, we measured a RCP equal to 97.9% and to 96.8%, respectively. The 1.1% difference between the measured RCP shows a good accuracy of the optical approach. The analysis of the images of two strips treated with 99mTc-HMDP obtained with the two systems confirms the efficiency of the optical method. We observe that a quantitative analysis of CSs can be done using 10 sec (or even less) of exposure time with an optical system For this reason, the optical approach provides a quicker method to evaluate RCP with respect to the conventional one that takes few minutes. Furthermore the fusion of photographic and emissive images allows spatially localizing signals, permitting a convenient simultaneous analysis of different samples that cannot be done using conventional methods. The results show that the intensifying screen, even if is optimized for low energy X rays, can be reliably used also for γ and β radiations conversion.

Alpha- versus beta-emitting particles for pretargeted radioimmunotherapy of CEA-expressing human colon cancer xenografts

S. Heskamp[1], R. Hernandez[2], J. D. M. Molkenboer-Kuenen[1], M. Essler[3], F. Bruchertseifer[4], A. Morgenstern[4], W. J. G. Oyen[1], C. Seidl[5], W. McBride[6], D. M. Goldenberg[6], O. C. Boerman[1]; [1]Radboud University Medical Center, NIJMEGEN, NETHERLANDS, [2]University of Wisconsin, Madison, WI, UNITED STATES, [3]University of Bonn, Bonn, GERMANY, [4]Joint Research Centre – Institute for Transuranium Elements, Karlsruhe, GERMANY, [5]Klinikum rechts der Isar der Technischen Universität München, Munchen, GERMANY, [6]Immunomedics, Morris Plains, NY, UNITED STATES

Aim: Pretargeted radioimmunotherapy (PRIT) with the anti-CEA x anti-HSG bispecific antibody TF2, and ^{177}Lu-labeled di-HSG-DOTA peptide IMP288, can delay growth of CEA-expressing xenografts. A phase I study has shown the safety and feasibility of PRIT in colorectal cancer patients. The therapeutic efficacy of PRIT may be improved by using alpha-emitting radionuclides. The aim of this study was to compare the therapeutic efficacy of ^{213}Bi and ^{177}Lu for PRIT of CEA-expressing xenografts. Material and methods: The vitro binding characteristics (IC_{50}, K_d, internalization) of ^{213}Bi-IMP288 were compared to ^{177}Lu-IMP288. Tumor targeting of ^{213}Bi-IMP288 and ^{177}Lu-IMP288 was studied in mice with s.c. LS174T tumors that were pretargeted with TF2. Finally, the effect of ^{213}Bi-IMP288 (6, 12, or 17 MBq) and ^{177}Lu-IMP288 (MTD: 60 MBq) on tumor growth and survival was assessed. Toxicity was determined by monitoring body weight and by analyzing blood samples for haematological toxicity (haemoglobin, leucocytes, platelets). Results: Binding characteristics of ^{213}Bi-IMP288 were similar to ^{177}Lu-IMP288 (K_d = 0.8 nM). Tumor uptake was observed as early as 15 min post injection (9.2 ± 2.0 %ID/g) and the peptide cleared rapidly from the circulation. At 30 min post injection the blood level of ^{213}Bi-IMP288 was 0.44 ± 0.28 %ID/g. Uptake of ^{213}Bi-IMP288 in normal tissues was very low, except for some

uptake in the kidneys (1.8 ± 1.1 %ID/g). The biodistribution was comparable to ^{177}Lu-IMP288. PRIT treated mice showed significant inhibition of tumor growth and prolonged survival. Mean tumor doubling time for the PBS, 6 MBq ^{213}Bi-IMP288, 12 MBq ^{213}Bi-IMP288, and 60 MBq ^{177}Lu-IMP288 group was 3.3 ± 0.3, 6.5 ± 1.2, 11.1 ± 3.2, and 11.8 ± 9.3 days. Median survival for the PBS and 6 MBq ^{213}Bi-IMP288 group was 22 and 31 days, respectively. The 12 MBq ^{213}Bi-IMP288 and 60 MBq ^{177}Lu-IMP288 groups did not yet reach the median survival at day 35. Mice receiving 17 MBq ^{213}Bi-IMP288 showed significant weight loss, resulting in a median survival of 24 days. Tumor doubling time could not be reliably estimated for this group. No changes in haemoglobin, platelets, and leucocytes were observed. Conclusion: This study showed that PRIT with ^{213}Bi-IMP288 is feasible and at least as effective as ^{177}Lu-IMP288. Haematological toxicity and survival of mice treated with 12 MBq ^{213}Bi-IMP288 and 60 MBq ^{177}Lu-IMP288 were comparable. Future experiments should study the effect of multiple cycles ^{213}Bi- and ^{177}Lu-IMP288 on tumor growth, survival, and haematological and renal toxicity.

OP486

Targeted Radionuclide Therapy using high-LET particle emitter-labeled vectors against alpha-v-beta6-expressing cancers

S. PAILLAS[1], A. DESAI[2], I. QUETIER[2], J. MARSHALL[2], J. POUGET[3], J. SOSABOWSKI[1]; [1]Centre for Molecular Oncology, Barts Cancer Institute, London, UNITED KINGDOM, [2]Centre for Tumor Biology, Barts Cancer Institute, London, UNITED KINGDOM, [3]Inserm U1194, Montpellier, FRANCE

Targeted radionuclide therapy (TRT) has emerged as an attractive approach in cancer therapy since it allows the specific irradiation of tumor cells while sparing healthy tissues. TRT of solid tumors has a limited efficacy mainly because these tumors have high radioresistance and take up limited amounts of radiolabeled vectors. Strategies to overcome this include the use of small peptides and radionuclides that emit highly cytotoxic particles, namely high linear energy transfer (LET) particles such as alpha particles and Auger electrons. The epithelial-specific integrin avb6 is weak or absent on normal tissues but is upregulated in many cancers and is strongly associated with reduced survival. We have previously shown in vivo tumour targeting using radiolabelled A20FMDV2 a 20-mer avb6-specific peptide. Aims: The aim of the study is to assess the efficacy and toxicity of TRT in mice using both an internalising radiolabeled peptide and non-internalising monoclonal antibody (mAb) against avb6. The second aim is to validate in vivo gamma-H2AX (through γ-H2AX-MDC1 interaction) measurement as an indicator of the efficacy or toxicity of TRT by a novel quantitative and noninvasive imaging approach. Materials and methods: The 20 mer high affinity avb6-targeting peptide, A20FMDV2 used in previous work has been derivatised to contain a trimethylstannyl benzamide moiety so that it can be radiolabelled with high LET particle emitters: Auger electron emitter 125I and alpha particle emitter 211At. The peptide has been radiolabelled with 125I and radioligand binding and internalization assays have been carried out in cells that overexpress avb6 and compared with that of the 111In-DTPA-A20FMDV2 studied previously. In addition, lentiviral vectors encoding the reporter genes (γ-H2AX/MDC1-Luc2) were made by molecular cloning and used to coinfect avb6 expressing cells. To verify that our γ-H2AX/MDC1-Luc2 reporter functions well in tissue culture, stably infected cells were exposed to varying degrees of stress and the activities of reporter genes was observed by bioluminescence imaging and by western blot analyses of phosphorylated H2AX or Nluc2-H2AX. Results and conclusions: The peptide could be radiolabelled with radiolabelling efficiencies of 80-90% and purified to 100 % using Sep-Pak. Radioligand saturation binding assays show Kd and internalization rate comparable with that of the 111In-DTPA construct. Robust reporter activation can be observed in cells coinfected with reporter genes γ-H2AX/MDC1-Luc2 by bioluminescence imaging and western blot. These cells will be xenografted in mice to evaluate double strand breaks in vivo after TRT.

OP487

Involvement of direct and indirect (bystander) cytotoxic effects in alpha-RIT of small volume peritoneal carcinomatosis using ^{212}Pb-labeled mAbs

J. Pouget[1], R. Ladjohounlou[1], A. Pichard[1], V. Boudousq[1], S. Paillas[1], M. Le Blay[1], C. Lozza[1], M. Bardies[2], S. Marcatili[2], N. Chouin[3], J. Torgue[4], I. Navarro-Teulon[1]; [1]IRCM/INSERMU1194, MONTPELLIER, FRANCE, [2]UMR 1037 INSERM/UPS, TOULOUSE, FRANCE, [3]AMAROC, ONIRIS, Nantes, FRANCE, [4]AREVA Med, BETHESDA, WI, UNITED STATES

Hypothesis: We investigated in vitro and in vivo the relative contribution of direct and indirect (bystander) effects in the therapeutic efficacy of 212Pb-labeled mAbs used for treating small volume peritoneal carcinomatosis.Methods: In vitro, we investigated in A-431 cells exposed to increasing activities (0-0.5 MBq/mL; 37 MBq/mg) of either 35A7 (anti-CEA), Trastuzumab (anti-HER2) or PX (non-specific) 212Pb-labeled mAbs the relative contribution to cell killing of direct and bystander effects using standard medium transfer protocol. Biological end points included clonogenic survival and oxidative DNA damage including DNA double strand breaks measured both in donor (direct effect) and in recipient cells (bystander effects). Mean absorbed dose to the nucleus of donor cells was also determined using MIRD formalism. In vivo,

nude mice with intraperitoneal (i.p.) 2-3 mm A-431 tumor cells xenografts were i.p. injected with increasing activities (370-1480 kBq; 37 MBq/mg) of the above mentioned anti-CEA, anti-HER2 or non-specific 212Pb-mAbs. Determination of radioactivity at the tissue level was done using digital micro-autoradiography (DAR) and absorbed doses were calculated. Biological markers including 53BP1, caspase 3 and Ki67 proteins were also determined in tissue by immunohistochemistry. Results: In vitro we showed in donor cells the strong efficacy of 212Pb-35A7 and 212Pb-trastuzumab mAbs and also to a lower extent of 212Pb-PX mAb. Significant bystander cytotoxicity was measured in all recipient cells with the three radiolabeled mAbs. The complexity of DNA damage (53BP1 foci) observed in donor cells confirmed the high LET cytotoxic effects of 212Pb-mAbs while less complex damage were observed in recipient cells. In vivo, dose distribution was calculated using DAR analysis and voxel dosimetry. Results showed a strong dose gradient for anti-CEA 212Pb-mAbs while it was much more homogeneous for anti-HER2 or for the non-specific 212Pb-mAbs. These results explain the relative higher therapeutic efficacy previously reported in vivo for anti-HER2 212Pb-mAbs compared with anti-CEA 212Pb-mAbs. However, we also observed a similar formation of DNA damage in tissue independently of tumour absorbed doses thereby indicating that bystander effects could also be involved. Conclusions: Our results showed in vitro and in vivo the strong direct effects of 212Pb-labeled mAbs in killing tumour cells. Heterogeneity in mAbs distribution would explain the relative lack of efficacy per Gy (to the whole tumour) of anti-CEA mAbs compared with anti-HER2 mAbs. However, our preliminary data indicate that bystander effects would participate to 212Pb-labeled mAbs efficacy.

OP488

Targeted Alpha Radionuclide Therapy of Prostate Cancer Using a Small Molecule Inhibitor of Prostate-specific Membrane Antigen (PSMA)

K. L. S. Chatalic[1,2,3], S. Heskamp[4], J. Nonnekens[1,5], J. D. M. Molkenboer-Kuenen[4], D. van Gent[5], F. Bruchertseifer[6], A. Morgenstern[6], M. Weineisen[7], H. Wester[7,8], W. M. van Weerden[3], O. C. Boerman[4], M. de Jong[1,2]; [1]Department of Nuclear Medicine, Erasmus MC, Rotterdam, NETHERLANDS, [2]Department of Radiology, Erasmus MC, Rotterdam, NETHERLANDS, [3]Department of Urology, Erasmus MC, Rotterdam, NETHERLANDS, [4]Department of Radiology and Nuclear Medicine, Radboud University Medical Centre, Nijmegen, NETHERLANDS, [5]Department of Genetics, Erasmus MC, Rotterdam, NETHERLANDS, [6]Joint Research Centre – Institute for Transuranium Elements, Karlsruhe, GERMANY, [7]Pharmaceutical Radiochemistry, Technische Universität München, Munich, GERMANY, [8]Scintomics GmbH, Fürstenfeldbruck, GERMANY

Objectives: PSMA is a well-recognized target for imaging and therapy of prostate cancer (PCa); it is expressed in a very high percentage of PCa lesions. Radiolabeled PSMA-inhibitors localize rapidly to tumor lesions, including soft-tissue and bone metastases, but show high uptake in kidneys and salivary glands. The aim of the present study was to evaluate the potential of the alpha emitter ^{213}Bi coupled to PSMA I&T, a DOTAGA-chelated urea-based PSMA inhibitor, for therapy in PSMA-expressing tumor cells *in vitro* and *in vivo* in mouse xenografts. Materials and Methods: PSMA I&T was labeled with ^{111}In or ^{213}Bi. Pharmacokinetics of ^{111}In-PSMA I&T were evaluated in mice bearing subcutaneous PSMA-expressing LNCaP tumors and PSMA-transfected LS174T tumors. Biodistribution was determined 2h after ^{111}In-PSMA I&T injection (0.1-10 nmol). Blocking of PSMA-specific binding to kidneys was investigated by co-injecting 2-(phosphonomethyl)pentane-1,5-dioic acid (PMPA). The therapeutic efficacy of ^{213}Bi-PSMA I&T was tested *in vitro* in LNCaP cells and *in vivo* in LNCaP-xenografted mice. Cells were incubated (20 min) with ^{213}Bi-PSMA I&T, ^{213}Bi-DTPA, or medium, and fixed at 1, 2, 4, 24, and 48h after treatment. Mice were injected with ^{213}Bi-PSMA I&T (0.2 nmol, 5 MBq). Biodistribution was determined at 1h after injection, whereas tumor and kidneys were dissected at 1h and 24h after injection to study the therapeutic DNA-damage response. Fixed tumor cells and dissected tissues were stained with anti-53BP1 and anti-GEMININ antibodies and a TUNEL detection kit. Results: ^{111}In-PSMA I&T showed dose-dependent uptake in LNCaP and LS174T-PSMA tumors (t), kidneys (k), spleen, adrenals, lung and salivary glands. Optimal doses for tumor targeting were 0.1-0.3 nmol. Co-injection of 10 nmol PMPA resulted in a decrease in renal and tumor uptake of 60% and 17%, respectively, improving t/k ratio. Treatment of LNCaP cells with ^{213}Bi-PSMA I&T caused a decrease in cellular proliferation, induction of DNA double-strand breaks and apoptosis. The biodistribution patterns of ^{213}Bi-PSMA I&T and ^{111}In-PSMA I&T were similar. ^{213}Bi-PSMA I&T induced DNA-double strand breaks in LNCaP tumors, from which a significant amount was not repaired at 24h after injection. Conclusion: PSMA I&T is a promising targeting agent for radionuclide therapy of PCa. In this study we showed renal accumulation of this tracer to be efficiently reduced by co-injection of PMPA, while tumor uptake was preserved. Our preliminary results reveal a good targeting and therapeutic effect of ^{213}Bi-PSMA I&T *in vitro* and *in vivo*.*K.L.S.C. and S.H. contributed equally to this work

OP489

The next step in increasing the efficacy of PRRT: Preclinical studies in vicvo and in vitro with ^{213}Bi-[DOTA^0,Tyr^3]-octreotate

H. S. Chan[1], **M. W. Konijnenberg**[1], E. de Blois[1], S. Koelewijn[1], T. Anderson[2], M. Nysus[2], W. A. P. Breeman[1], R. W. Atcher[3], A. Morgenstern[4], F. Bruchertseifer[4], J. P. Norenberg[2], M. de Jong[1]; [1]Nuclear Medicine and Radiology, Erasmus MC, ROTTERDAM, NETHERLANDS, [2]College of pharmacy, University of New Mexico, Albuquerque, NM, UNITED STATES, [3]Los Alamos National Laboratory, Los Alamos, NM, UNITED STATES, [4]European Commission, JRC, Institute for Transuranium Elements, Karlsruhe, GERMANY

Peptide Receptor RadioTherapy shows a reasonable objective response rate of 30-35% with the use of ^{177}Lu-[DOTA^0,Tyr^3]-octreotate (^{177}Lu-DOTATATE). Alpha-particle emitters can augment the therapeutic efficacy of PRRT and make it exceptional, especially in small tumours and metastasis cell clusters. In preclinical studies with alpha-emitter labeled peptides high specific activity is required, because of the high-affinity, but low-capacity of tumour cell receptors. The stability of -particle emitting radiopeptides should be maintained until receptor mediated uptake, both *in vivo* as *in vitro*, to minimize off-targeting effects. Also the radio-peptide should have rapid uptake, high retention in tumour tissue and it should show high clearance capacity from normal tissue. In this study we optimized the application of ^{213}Bi-DOTATATE for targeted alpha-particle therapy *in vitro* and *in vivo*. We investigated for various somatostatin receptor-positive tumour models in mice the therapeutic efficacy of ^{213}Bi-DOTATATE. The labeling procedure for ^{213}Bi-DOTATATE was chemically optimized for preclinical applications. Materials and methods: Therapeutic effects *in vitro* were compared between ^{213}Bi-DOTATATE and ^{177}Lu-DOTATATE, using CA20948 (rat pancreatic tumour) and BON (human carcinoid) cell lines. Uptake in AR42J-bearing nude mice was investigated. Specific peptide receptor binding versus peptide mass, reduction of renal uptake by L-lysine, and mitigation of renal damage after PRRT were determined for ^{213}Bi-DOTATATE. Therapeutic efficacy of ^{213}Bi-DOTATATE was also investigated in CA20948- and H69 (human small lung carcinoma)-bearing nude mice, bearing tumours of different volumes. All experiments were guided by dosimetry to estimate the dose limits in organs and tumours and the relative biological effect of ^{213}Bi-DOTATATE compared to ^{177}Lu-DOTATATE. Results: Labeling of ^{213}Bi-DOTATATE was optimized for preclinical applications under physiologically acceptable conditions. ^{213}Bi-DOTATATE showed more effective cell killing *in vitro* in comparison to ^{177}Lu-DOTATATE at comparable absorbed doses. Tumour uptake *in vivo* depends on the peptide amount and therefore on specific activity. Renal uptake and absorbed renal doses could be decreased by pre-administration of L-lysine, thereby leading to higher tolerated activities and longer survival in nude mice. The therapeutic responses of small and large tumours after ^{213}Bi-DOTATATE did not show differences; in both being highly efficacious. Tumour growth delays of 50 days and more could be achieved compared to 30 days after ^{177}Lu-DOTATATE.Conclusions:^{213}Bi-DOTATATE has proven to be promising and safe in tumours with somatostatin receptor expression over a range of tumour volumes in mice. Optimal labeling conditions were determined for preclinical therapy studies in mice and renal toxicity could be managed by addition of L-lysine.

OP490

Preclinical Comparison of Therapeutic response to Treatment with 177-Lutetium labelled Somatostatin Receptor Agonists and Antagonists

S. Dalm[1], G. Doeswijk[1], S. Koelewijn[1], H. Maecke[2], M. de Jong[1]; [1]Erasmus MC, Rotterdam, NETHERLANDS, [2]University of Basel, Basel, SWITZERLAND

Introduction: Somatostatin receptor (SSTR) agonists are successfully being used in the clinic for radionuclide-mediated imaging and therapy of neuroendocrine tumors. Recently, studies showed a higher tumor uptake of SSTR antagonists compared to SSTR agonists. Furthermore, first studies on the feasibility of imaging and therapy of patients with SSTR antagonist showed promising results. However, to date no studies have been performed to compare the differences in therapeutic effect between SSTR agonists and SSTR antagonists. The aim of this project was to determine differences in therapeutic response after treatment with ^{177}Lu-Octreotate, an SSTR agonist, and ^{177}Lu-JR11, an SSTR antagonist, in preclinical studies in an in vivo mouse model. Materials and Methods: Male balb c nu/nu mice were subcutaneously inoculated with the SSTR-positive H69 cell line. For biodistribution purposes mice were injected with ~30 MBq ^{177}Lu coupled to 0.5, 1.0 and 2.0 μg JR11. At 4 time points (4 h, 2 d, 4 d and 7 d) post injection, tumors and organs were collected and radioligand uptake was determined. Also, therapy studies were performed comparing the effect of ^{177}Lu-Octreotate and ^{177}Lu-JR11. Animals (n=6 each group) were injected with either 0.5 μg/~30MBq ^{177}Lu-JR11, ^{177}Lu-Octreotate, after injection of 4 mg Gelofusin to reduce renal uptake, or received a sham injection. Animals were euthanized when tumor size reached 2000 mm^3. Results: Biodistribution studies showed 0.5 μg/30 MBq ^{177}Lu-JR11 to result in the highest tumor radiation dose (1.8±0.7 Gy/MBq), with lowest variation. Data was compared to previously performed biodistribution studies using ^{177}Lu-Octreotate in the same

mouse model. ^{177}Lu-JR11 tumor radiation dose was significantly higher than the optimal tumor dose reported for ^{177}Lu-Octreotate (0.4±0.1 Gy/MBq). Tumor-to-kidney ratio of ^{177}Lu-JR11 stayed the same for all peptide concentrations tested, but was significantly higher for ^{177}Lu-JR11 compared to ^{177}Lu-Octreotate; 0.97±0.32 Gy/MBq vs. 0.14±0.05 Gy/MBq respectively, using 0.5 μg/~30 MBq of both radiotracers. Five weeks after injection of a therapeutic dose of ^{177}Lu-JR11 or ^{177}Lu-Octreotate, survival in the 2 groups was 80% and 17%, respectively, while none of the animals of the control group survived up to that time point. Growth delay time was superior for animals treated with ^{177}Lu-JR11 (68±5 d) compared to ^{177}Lu-Octreotate (57±5 d) and control animals (41±6 d). Conclusion: The SSTR antagonist, JR11, showed higher uptake and a better therapeutic effect compared to the SSTR agonist, Octreotate, in H69 xenografts. Therefore, we conclude that the SSTR antagonist, JR11, may positively contribute to SSTR mediated imaging and therapy.

OP491

[177Lu]-OPS201 targeting somatostatin receptors: In vivo biodistribution and dosimetry in a pig model

S. Beykan[1], J. S. Dam[2], U. Eberlein[1], J. Kaufmann[3], B. Kjærgaard[4], L. Jødal[2], H. Bouterfa[3], M. Lassmann[1], S. B. Jensen[5]; [1]Department of Nuclear Medicine, University of Würzburg, Würzburg, GERMANY, [2]Department of Nuclear Medicine, Aalborg University Hospital, Aalborg, DENMARK, [3]Octreopharm Science GmbH, Berlin, GERMANY, [4]Biomedical Research Laboratory, Aalborg University Hospital, Aalborg, DENMARK, [5]Department of Nuclear Medicine, Aalborg University Hospital, Department of Chemistry and Biochemistry, Aalborg University, Aalborg, DENMARK

Aim: OPS201 is a new somatostatin receptor antagonist with high affinity towards the somatostatin receptor subtype sst2. In combination with 177Lu it can potentially be used for peptide receptor radionuclide therapy (PRRT) in patients with neuroendocrine tumors. Here we present the in vivo bio distribution of 177Lu OPS201 in pigs as a model for human dosimetry. Materials and Methods: All procedures involving animals were performed after a written permission from the Danish Animal Experiments Inspectorate. [177Lu]-OPS201 was produced on an E&Z Modular lab PharmTracer system by reacting 24 nmol of OPS201 precursor with [177Lu]-Chloride n.c.a. (ITG) in a sodium acetate / ascorbate buffer (pH 4.5) at 80°C for 20 minutes. In vivo biodistribution and dosimetry studies with 100 MBq (+/-10 MBq) [177Lu]-OPS201 were performed in anesthetized Danish Landrace pigs (2 female and 3 male, age 3 months, weight: 28 kg (+/- 2 kg)). A series of SPECT/CT scans were conducted until 10 days after intravenous injection. The physiological parameters were monitored and if necessary, corrected during the scans. Blood samples were taken to determine the time-activity curves in blood. Time-activity curves and residence times were calculated for the organs showing visible uptake. Based on these data, the absorbed organ dose coefficients for a 70kg patient were calculated using the OLINDA/EXM software. Result: The applied radio labeling procedure yielded [177Lu]-OPS201 (62-88%, non-decay corrected, RCP>98%). After injection, the blood samples showed fast clearance of the compound from the blood. Less than 5% of the injected activity was observed in the blood 10 min after injection. There was no visible uptake in the spleen but measurable uptake in the spine. For humans after an injection of 5 GBq [177Lu]-OPS201, the highest calculated absorbed doses were registered in the kidneys (13.7Gy), the osteogenic cells (3.9Gy), the urinary bladder wall (1.8Gy), and the liver (1.0Gy). None of the absorbed doses exceed organ toxicity levels. No metabolites of [177Lu]-OPS201 were found by radio HPLC analysis. Conclusion: In vivo distributions and absorbed doses are generally comparable to those obtained for other therapeutic somatostatin receptor ligands. However for a human study the potential uptake to the spine and the spleen need to be analyzed carefully. The analysis shows no indication that a human study leads to an overexposure of patients after giving a normal treatment of 5-7 GBq with [177Lu]-OPS201.

OP492

Development and human absorbed dose estimation of 47Scandium-anti-CD20 for radioimmunotherapy

L. Moghaddam-Bnaem[1], A. Jalilian[2]; [1]Amirkabir Technical university, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Nuclear Science and Technology Research Institute, Tehran, IRAN, ISLAMIC REPUBLIC OF

Aim: In this investigation a new radiopharmaceutical using ^{47}Scandium for labeling Anti-CD20 is performed. Rituximab monoclonal antibody is selectively binds with high affinity to CD20 antigen, a surface antigen common in B-cell of lymphoid tissue. Scandium-47 is a moderate energy β- emitter (T1/2 = 3.42d, Eβmax= 441 keV ,%68; Eβmax= 600 keV , %32). Because the availability of 47Sc isotope is currently extremely limited, we have performed preliminary studies using 46Sc which is chemically identical. The chemical procedure, biodistribution in wistar rats and the absorbed dose of radiation into human organs by using biodistribution data in rats, after an intravenous administration of ^{47}Scandium-labeled Rituximab, were estimated. Material and Methods: In this work, Sc-46 chloride was obtained by thermal neutron activation flux of natural metallic scandium sample followed by dissolution in acidic media (radionuclidic purity via beta and gamma ray spectroscopy, 99.9% ; radiochemical purity

via ITLC, >99%) and used in radiolabeling of rituximab after conjugation with DOTA-NHS-ester The radiochemical purity (ITLC), stability studies (ITLC and size exclusion chromatography), determination of average number of DOTA conjugated per mAb (chelate: antibody ratio, 5.8:1) were determined followed by biodistribution studies for 46Sc and [46Sc]Sc-DOTA-anti-CD20 in wild type rats up to 72h. The biodistribution data in rats were analyzed to estimate the human's organs uptake and source organ residence times and cumulated activities. The dose calculation and estimation was done for a certain group of organs of human following the MIRD technique. As the S-factor is relevant to the particle energy that emitted by radionuclide for dose calculation the dose S-factor of ^{47}Sc is used. Results and conclusion: The binding of the radiolabeled antibody was showed to be 60% on Raji cells. The final compound was stable in presence of PBS at 37 °C and room temperature. The accumulation of the radiolabeled antibody in liver, spleen, kidney, heart and other tissues demonstrates a pattern similar to the other radiolabeled anti-CD20 immunoconjugates. The accumulation of the radiolabeled antibody in liver, spleen, kidney, heart and other tissues demonstrates a pattern similar to the other radiolabeled anti-CD20 immunoconjugates.The absorbed dose of ^{47}Sc -Riruximab in human is also estimated. The absorbed dose in human by lung, stomach, S intestine, liver, spleen, kidney and bone are 0.09, 0.06, 0.02, 2.94, 0.79, 0.13 and 0.27mGy/MBq respectively. The present study shows the possibility of antibody labeling for future use in radioimmunotherapy by 47Sc.

Clinical Impact of simultanous ^{18}FET PET/MRI for Pediatric CNS-tumors

L. Marner[1], K. Nysom[1], A. Sehested[1], L. Borgwardt[1], R. Mathiasen[1], P. S. Wehner[2], M. Jørgensen[1], P. Munck af Rosenschöld[1], C. Thomsen[1], L. Bøgeskov[1], H. Broholm[1], D. Scheie[1], M. Juhler[1], L. Højgaard[1], I. Law[1]; [1]Copenhagen University Hospital, Rigshospitalet, Copenhagen O, DENMARK, [2]Odense University Hospital, Odense, DENMARK

Aim: We aim to investigate the diagnostic value of simultaneous ^{18}F-flouro-ethyl-tyrosine positron emission tomography and MRI (^{18}F-FET PET/MRI) in comparison to MRI alone for primary CNS-tumors in children and adolescents at the time of diagnosis, before and after surgery, and if relapse or progression is suspected.Material and Methods: We aim to include 100 consecutive children and adolescents diagnosed with a primary CNS-tumor before the age of 18, and have so far included 8 patients (3-15 years). All but two required anesthesia and in half of the cases, the ^{18}F-FET PET/MRI replaced a regular MRI. Simultaneous with MRI of the brain (+/- spinal canal), a 40 min dynamic PET recording was performed using a 3T Siemens Biograph mMR after injection of 3 MBq/kg ^{18}F-FET. The PET images were reconstructed using a low-dose CT for attenuation correction. A summed image of the last 20 min of the PET recording was evaluated as PET uptake in tumor relative to unaffected gray matter as described previously*. The clinical impact of the FET PET/MRI was evaluated at a multidisciplinary team meeting by first considering the MRI and deciding the future plan and subsequently considering the PET/MRI and evaluating the possible changes in plans. Results: For 10 of 14 eligible patients, the parents have given consent for participation; 8 have been scanned. The patients had pilocytic astrocytoma WHO grade I (n=3, 2 with FET uptake, 1 without tumor residue), pilomyxoid astrocytoma WHO grade II (FET uptake), DNET WHO grade I (no FET uptake), ependymoma WHO grade II (FET uptake), atypical teratoid/rhabdoid tumor WHO grade IV(FET uptake), unbiopsied lesion suspected of tumor (no FET uptake). In 2 out of 8 cases, FET PET/MRI had a major clinical impact or gave support to a difficult clinical decision: One case changed the operation procedure by including an extra tumor focus. In another case, FET PET/MRI supported interpreting spinal changes as being artifact and not indicative of dissemination, thus reducing the radiation field from craniospinal to focal. Conclusion: The use of simultaneous ^{18}F-FET PET/MRI instead of MRI only is feasible with minimal need for extra anesthesia. The preliminary results show a major clinical impact of ^{18}F-FET PET/MRI in 2 of 8 cases. If further data supports a high percentage of clinical impact, we suggest a more regular use of this modality in children and adolescents with primary CNS-tumors.*Dunkl et al. (2015) JNM 56:88-92.

OP495

Evaluation of Early Response to Neoadjuvant Chemotherapy with FDG PET/CT and MRI in Pediatric Patients with Bone Sarcoma

M. Caglar, B. Aydin, B. Ergen, E. Karabulut, C. Akyuz; Hacettepe University, Ankara, TURKEY

Objective: 18F-FDG-PET/CT and diffusion-weighted MRI were used for predicting response to treatment in patients with

bone sarcomas in this study. Correlation between PET and MRI parameters with histopathological response and clinical outcome was assessed. Materials - Method: Sixteen patients (5 osteosarcoma, 11 Ewing's sarcoma) aged between 5-16 years were included in study. All patients underwent 18F-FDG-PET/CT and diffusion MRI before (PET1 and MR1) and after preoperative chemotherapy (PET2 and MR2) to assess the radiological tumor response. The number and localization of 18F-FDG involvements, "maximum standardized uptake" value (SUVmax), metabolic tumor volume (MTV) and total lesion glycolysis (TLG) in 18F-FDG-PET/CT, and tumor volume and apparent diffusion coefficients (ADC) from three separate areas within tumor on MRI were measured. Changes in parameters before and after treatment were compared with histopathological tumor response. Results: PET/CT at diagnosis showed 18F-FDG uptake in 1-32 different anatomical regions. Median SUVmax1 and TLG1 values at baseline were 6.0 (ranged between 2.6-9.4) and 127.0 (ranged between 8.2-573.3), respectively. Eight patients with good histologic response had lower median post-chemotherapy FDG-PET/CT parameters compared to those with poor response (1.7 vs 3.0 for SUVmax2 and 5.0 vs 62.5 for TLG2, respectively). The correlation coefficients between tumor necrosis and SUVmax2 and TLG2 were -0,647 and -0,656 respectively, $p<0,05$). Based on ROC curve analysis, SUVmax2 and TLG2 predicted a good pathological response. The optimal cut-off values for SUVmax2 and TLG2 were 2,25 and 43,85 which yielded a sensitivity/specificity of 0,83/0,75 and 0,67/100 respectively. Median diffusion MRI ADC changes were found 27.6 and 46.9 in poor and good responders, respectively ($p>0.05$, 8 patients). Conclusion: PET/CT can be used for identification of metastasis in patients with bone tumors on diagnosis and can predict the histopathological response after neoadjuvant therapy.

OP496

Clinical impact of FDG PET-CT in pediatric soft tissue sarcomas

M. Tuncel[1], N. Kurucu[2], P. Ö. Kıratlı[1], B. Erbaş[1], C. Akyüz[2]; [1]Hacettepe University, Department of Nuclear Medicine, ANKARA, TURKEY, [2]Hacettepe University, Department of Pediatric Oncology, ANKARA, TURKEY

Aim: The use of positron emission tomography-computed tomography (PET-CT) for the evaluation of pediatric patients with rhabdomyosarcoma has increased steadily over the last decade. The management of these tumors needs multimodality approach with accurate detection of disease burden. The aim of this study was to evaluate the clinical impact of PET/CT in pediatric patients suffering from rhabdomyosarcoma other osft tissue sarcoma. Materials and Methods: Between December 2011 and March 2015, 23 consecutive patients [F/M: 10/13, age median: 16±6.1 (range:3-22)] with 17 rhabdomyosarcoma and 6 with other soft tissue sarcomas were referred for FDG PET-CT. There were 40 referrals from 23 patients (9 for staging, 7 for equivocal conventional imaging, 13 for restaging and 11 for therapy response). Patient management-follow-up data, conventional imaging (CI) (30 with MRI, 4 with CT and 6 with both CT and MRI) and PET-CT results were than interpreted with pediatric oncologist to determine the clinical impact of the FDG PET-CT over CI and clinical evaluation. Results: FDG PET-CT detected malign disease in 30 referrals in 18/23 (78%) patients with median SUV max of 6±5 (range:2.5-24). In 5 patients FDG PET-CT was interpreted as normal without active metabolic disease. When compared to CI, FDG PET-CT has no clinical impact on patient management in 25/40 (62,5%) referrals (4 for staging, 9 for restaging and 11 for therapy response). In 15/40 (37,5%) referrals FDG PET had a major clinical impact (5 for staging, 7 for equivocal conventional imaging, 3 for restaging).In 7/15 (47%) of the referrals; FDG PET-CT changed treatment approach by changing the patients' stage (6 upstaged and and 1 down-staged). Therapy was ended due to true negative FDG PET-CT results in 3/15 (20%) patients, in 2/15 (13%) patients true positive PET leaded to more aggressive chemotherapy with the addition of radiotherapy. In 2/15 (13%) patients FDG PET-CT prevented therapy change to more extensive therapy by showing true negative results and in 1/15 (7%) patient FDG-PET-CT guided biopsy by showing metabolically active lesions. Conclusions: FDG PET/CT has a significant impact on the management of pediatric patients suffering from soft tissue sarcomas. It leads to a clinical decision change in 37.5% of the referrals especialy those referred due to equivocal CI. More studies are required for identifying the subgroup of patients who might benefit from a PET/CT.

OP497

Utility of PET/CT in children with Langerhans cell histiocytosis.

R. Czepczyński, E. Jodłowska, O. Zając-Spychała, M. Ruchała, J. Wachowiak; Poznan University of Medical Sciences, Poznań, POLAND

Introduction: Langerhans cell histiocytosis (LCH) is a very rare condition that primarily affects children. Its symptoms are caused by single or multiple tumors composed of Langerhans cells. Standard imaging modalities involved in the management do not include PET/CT. Aim of the study: To assess the utility of PET/CT in the management of children with LCH.Materials and methods: The study included 15 pediatric patients with LCH (age at diagnosis: from 3 months to

17 yrs., mean 4.8 ± 5.6 yrs., median 5.1 yrs.). 5 children had single system LCH, 10 children had multiple system LCH. Patients were treated in accordance with the current guidelines of Histiocyte Society (LCH-2009) using prednisone, vinblastine and 6-mercaptopurine. PET/CT using 18F-FDG was performed 60 min after injection of 18F-FDG using a routine protocol with Discovery ST scanner (GE) and compared with clinical status and other imaging modalities (CT, ultrasonography, MRI). Results. PET/CT was performed for staging of the disease (6 pts.), for the evaluation of treatment response (5 pts.), for the evaluation of treatment effect (10 pts.). Most patients had more than one PET/CT scan. Altogether 33 PET/CT scans were retrospectively evaluated (max. 6 PET/CT scans per one patient). In 5/6 cases the scan performed for staging showed FDG-avid foci in the bones (5), orbita (2), subcutaneous tissue (2) and liver (1). Only in one patient, small subcutaneous lesions showed no uptake of FDG. In none of the 3 patients with lung involvement pulmonary FDG uptake was found. PET/CT performed during chemotherapy for response evaluation, slight FDG activity was visible in 3/5 patients. Complete metabolic response was reported in 2/5 patients. At the final treatment evaluation of these 5 patients complete metabolic response was found in 4 patients and persistent uptake in one patient (non-responder according to the early scan and progression was observed in the subsequent PET/CT). The late evaluation showed disease recurrence in 2/10 children. Comparison with other imaging modalities showed that the reduction of FDG uptake during treatment preceded morphological remission and was a predictor of treatment response. Conclusions: Despite the heterogeneity of this small group, our experience confirms the utility of PET/CT in the management of LCH. Prospective studies are warranted to evaluate prognostic significance of PET/CT, especially with regard to the interim and post-therapy scans.

OP498

Value of FDG PET-CT in the therapy evaluation of Hodgkin's lymphoma

M. Tuncel[1], T. M. Kutluk[2], P. Ö. Kıratlı[1], B. G. Aydın[2], B. Erbaş[1], C. Akyüz[2]; [1]Hacettepe University, Department of Nuclear Medicine, ANKARA, TURKEY, [2]Hacettepe University, Department of Pediatric Oncology, ANKARA, TURKEY

Aim: 18 FDG PET-CT is a validated tool for staging and therapy response evaluation of Hodgkin's lymphoma (HL). FDG PET-CT offers several quantitative and qualitative parameters for the evaluation of therapy response. However the optimal parameter for prediction of therapy response and prognosis is yet to be determined. In this study we aimed to share our experience with FDG PET-CT in the management of patients with HLMaterial and method:18 FDG PET-CT was performed in 45 pediatric Hodgkin's lymphoma (mean age: 12.6±4, range: 4-20 yrs) at baseline (1) and after 2-3rd cycles of chemotherapy (interim)(2). End of therapy imaging (3) was available in 30 patients. The median follow-up was 20 months (4-46). Images were interpreted according to the Deauville 5-point score (DS). In addition, SUVmax values of the dominant lesion, diameter (dia) of the lesion on CT was measured. Percentage change of SUVmax and diameter values were also measured. The ROC curves were obtained to determine the AUC values and the optimal cut-off of parameters to predict relapse. Results: Interim PET-CT was normal in 75% of patients. DS 4-5 was in 23% of group. Six patients had progression or relapse during follow-up. SUV2 [0.5 ± 1.1(0-4) vs 6.6 ± 7.9 (0-5.2), p=0.024], SUV3 [0.6 ±1.4 (0-5.2) vs 8.38 ±9.7 (2-25), p=0.001], CT3 [7.6 ±6.3 (0-23) vs 25.4 ±22 (10-61), p=0.022] values were different in remission and relapse sub-groups. The AUC values were 0.78 (p=0.025) for SUV2, 0.936 (p=0.02) for SUV3, and 0.82 (p=0.026) for Dia3, respectively. The best cut-off values were 2.7, 2.2, and 10.5 mm. with a sens., spec., PPV, NPV of 66.7%, 94.9%, 66.7%, 94.9 % for SUV2, 80%, 88%, 95.6%, %57.1 for SUV3, and 80%, 70.3%, 33%, 95% for Dia3., respectively. DS 4-5 had 83.3% sens., 66.7% spec., 36.4% PPV, 94.6% NPV. PFS (progression free survival) in patients with DS 1-3 was better than in patients with DS 4-5 (Log-rank, p=0.004). Patients with values below the cut-off of SUV2, SUV3 and Dia3, had longer PFS than patients with higher values (Log-rank, p=0.0001, p=0.001, p=0.032). Conclusion: FDG PET-CT was useful for the evaluation of pediatric patients with HL. Interim DS 4-5 and high SUV 3 were the best predictors of shorter PFS. Our results should be confirmed in studies with larger number of patients.

OP499

Pediatric Hodgkin Lymphoma: visual and semiquantitative analysis of interim 18FDG-PET/CT in predicting treatment response and outcome.

C. Ferrari[1], **A. Niccoli Asabella**[1], M. Fanelli[1], N. Merenda[1], T. Perrillo[2], P. Muggeo[2], F. De Leonardis[2], N. Santoro[2], G. Rubini[1]; [1]Nuclear Medicine Unit, D.I.M., University of Bari "Aldo Moro", Bari, Italy, Bari, ITALY, [2]Department of Pediatric Hematology and Oncology, University of Bari "Aldo Moro", Bari, Italy., Bari, ITALY.

Background and aim: Interim 18FDG-PET/CT (PET-2) helps

predict outcome and tailor treatment in adults with Hodgkin Lymphoma (HL). In contrast, PET-2 data on pediatric HL are rare, with discordant results. Visual analysis using Deauville Score (DS) was proposed to assess PET response. However a 5-point scale did not preclude inter-observer reproducibility issues. Alternative approaches were developed to improve the accuracy and reproducibility of PET-2, mainly based on PET semi-quantitative parameters. We investigated the clinical usefulness of PET-2, evaluating both visual and semiquantitative analysis, in pediatric HL patients referred to a single center study. Materials and Methods: 18FDG-PET/CT was performed in 27 HL patients (age ≤16; average age: 12.8; 15 male:12 female) at baseline (PET-0), after 2 cycles of chemotherapy (PET-2) and at the end of treatment. PET response assessment was carried visually according to the DS, as well as semiquantitatively by use of absolute decrease in semiquantitative parameters from PET-0 to PET-2 (ΔsumSUVmax0-2, Δ∑SUVmean0-2, Δ∑MTV0-2, Δ∑TLG0-2) and the corresponding Response Indexes (RI%∑SUVmax0-2, RI%∑SUVmean0-2, RI%∑MTV0-2, RI%∑TLG0-2). Clinical response assessment was performed according the Cheson's Revised Response Criteria considering patients as responders (R) or non-responders (NR). Mean follow up was 23.3 months. T-student test for unpaired groups was performed to compare PET semiquantitative parameters between R and NR. Chi-square and Fisher exact test were performed to evaluate the association among categorical variables. The prognostic capability of 18FDG-PET/CT was calculated by ROC analysis and expressed as area under curve (AUC).Results: 5/27 (18%) patients were NR at the end of therapy based on clinical outcome and, among them, 2 became R in follow-up; another one remained NR while other two died. Visual assessment was: DS=1 in 14/27 (52%), DS=2 in 1/27 (3%), DS=3 in 4/27 (15%), DS=4 in 8/27 (30%) patients. Differences between R and NR were statistically significant for Δ∑SUVmax0-2 (t=2.45, p=0.026) and almost statistically significant for Δ∑SUVmean0-2 (t=1.88, p=0.071). No significant difference was found for the other parameters. Any association among Deauville evaluation and outcome at the end of therapy was found (Fisher exact test p=0.136). The better AUCs resulted for Δ∑SUVmax0-2 (0.836; cut-off<12.5, sensitivity 80%, specificity 91%). Conclusions: Semiquantitative analysis seems to be more accurate than visual analysis to interpret PET-2 and predict outcome in pediatric HL patients. In particular, Δ∑SUVmax0-2 appears to be the best PET parameters in predicting therapy response assessment in pediatric HL patients. The integration of Δ∑SUVmax0-2 with DS, could achieve to the best PET-2 performance.

OP500

Prognostic Value Of Different F-18 FDG PET/CT Quantitative Analytical Methodologies In Pediatric Hodgkin's Lymphoma

A. A. Kandeel[1], O. M. Serry[1], M. A. Alhussieny[1], W. O. Soliman[2]; [1]Kasr Alaini center of Oncology and Nuclear Medicine NEMROCK, Cairo, EGYPT, [2]57357 Children cancer Hospital, Cairo, EGYPT.

Introduction and aim of work: Assessment of the individualized SUVs, PET-derived total metabolic tumor volume (TMTV) and the product of both parameters, termed total lesion glycolysis (TLG) in both initial and interim PET if it carries a better PPV in early assessment of response to therapy in pediatric Hodgkin's lymphoma (PHL) patients. Patients and Methods: Retrospective analysis of PET/CT results was performed on 60 patients (42 males and 18 females; mean age 8.7±4.2 years). To assess the prognostic value of initial and interim 18F-FDG PET/CT, different semi-quantitative parameters such as SUVmax, SUVmean, Total lesion glycolysis (TLG) and TMTV of all lesions using SUVmax & mean including SUV2.5 and 40% of SUVmax as cut-off values were calculated. Follow up for 24 months from initial treatment with calculation of Disease Specific Survival (DSS). According to the recommendations of Deauville criteria interim PET (PET2) results were identified into three groups; PET2-negative (PET2-ve), PET2-positive (PET2+ve), and PET2-minimal residual uptake (PET2-MRU), the cut-off between PET2+ve and PET2-MRU was 3-4 in the 5-point scale. Results: Out of the 60 interim-PET scans, 50 scans were considered as PET2-ve (83.3%), 5 scans as PET2+ve (8.3%) and 5 scans as PET2-MRU (8.3%). The risk of the disease and the visual scoring assessment were significantly correlated with patient's outcome (whether Negative or Residual/Relapse) (p <0.0001). Different results were obtained; the most important were TLGmax2.5 (cut-off 2.5), TLGmean2.5 (cut-off 2) and TMTV2.5 (cut-off 0.75 ccm) in interim PET showed the highest sensitivity, specificity, PPV and NPV (58.5%, 97.9%, 87.5% and 90.3% respectively for the 3 parameters). Conclusion: TLGmax2.5, TLGmean2.5 and TMTV2.5 are the most relevant parameters for predicting the outcome in patients with PHL, and can add a significant prognostic

insight to interim PET response assessment. This may guide clinicians in their choice of therapeutic strategy.

G -SPECT-I: a full ring high sensitivity and ultra-fast clinical molecular imaging system with < 3mm resolution

F. J. Beekman[1], F. van der Have[2], M. C. Goorden[1], P. E. B. Vaissier[1], J. van Roosmalen[1], H. During[3], B. Vastenhouw[1]; [1]TU Delft, Delft, NETHERLANDS, [2]MIlabs, Utrecht, NETHERLANDS, [3]MILabs, Utrecht, NETHERLANDS

AIM: We developed G-SPECT-I, a full ring stationary clinical SPECT system designed to enable -for the first time- clinical imaging with isotropic resolution below 3 millimeter and with unique capabilities for low-dose studies and imaging of fast tracer dynamics. The aim of this paper is to present its initial results. METHODS & MATERIALS: G-SPECT-I is based on a stationary ring consisting of nine large field-of-view cameras with 595 × 472 mm NaI crystals, a 3D stage that allows optimal sampling during scanning, and an interchangeable nonagon-shaped collimator containing 54 pinhole apertures and with a bore diameter of 398 mm that makes the system suitable for brain, extremity or pediatric imaging. A proprietary graphical user interface (MILabs, Utrecht, The Netherlands) enables preselection of the field-of-view in three dimensions through optical images of the patient. This allows focusing the pinholes on the desired area of interest, thereby maximizing sensitivity and sampling density for the imaging task at hand. SPECT images are obtained from list-mode data using model-based 3D pixel-based OSEM reconstruction that utilizes PSF models of system blurring and position-dependent sensitivity to increase resolution. Using a Derenzo hot rod phantom containing 45MBq Tc-99m, G-SPECT-I was compared to a Siemens Symbia equipped with Low Energy High Resolution (LEHR) collimators and using Flash3D OSEM reconstruction with resolution recovery. Scan time on both systems was 15 minutes. RESULTS: The smallest hot rods resolved by G-SPECT-I had a diameter of 3 mm while the Siemens Symbia recovered only 7 mm rods. Peak sensitivity of G-SPECT-I was 415 cps/MBq compared to 182 cps/MBq for the Symbia. With G-SPECT-I dynamic imaging with time frames of <10s can be performed for focused scans and ~30s for imaging the entire brain. CONCLUSION: Initial G-SPECT-I images show a excellent isotropic resolution. Given the field-of-view available for this prototype and its unique potential for fast dynamic imaging first ground-breaking applications are expected in brain, bone and pediatric imaging, especially since -next to very high resolution- very fast imaging will be possible.

OP502

Double-Sided Readout with Digital Photon Counters Enables Millimeter Spatial Resolution and 150 ps Time Resolution in 32 mm x 32 mm x 22 mm Monolithic LYSO:Ce Crystals

B. J. Peet, G. Borghi, V. Tabacchini, **D. R. Schaart**; Delft University of Technology, Delft, NETHERLANDS

Reducing PET scanning times and radiation exposure while improving image quality and quantitative accuracy requires detectors with better detection efficiency, spatial resolution, and time resolution, all at the same time. Digital photon counter (DPC) arrays are fully digital, solid-state single-photon sensors. DPC arrays are almost transparent to 511 keV gamma quanta, opening up new degrees of freedom in PET detector design. This work demonstrates the improvement in spatial and time resolution that can be obtained by reading out a monolithic LYSO:Ce crystal by means of two DPC arrays, coupled to its front- and back surface in so-called dual-sided readout (DSR) configuration, in comparison to conventional back-side readout (BSR).DPC arrays consisting of 8 x 8 DPC pixels and having a total area of 32 mm x 32 mm were optically coupled to commercially available LYSO:Ce crystals having dimensions of 32 mm x 32 mm x 22 mm. Both BSR or DSR configurations were tested. The spatial-, time- and energy-resolutions of both configurations were measured. In conventional BSR configuration, a spatial resolution of ~1.5 mm FWHM and a DOI resolution of ~4 mm FWHM was obtained, averaged over the entire detector area. In DSR configuration, a spatial resolution close to 1 mm FWHM was achieved in combination with a depth-of-interaction (DOI) resolution of < 2.5 mm FWHM. The coincidence resolving time (CRT) in BSR and DSR configurations were ~225 ps FWHM and ~150 ps FWHM, respectively. Compared to BSR, the DSR configuration significantly improves the time-, spatial- and DOI resolutions of the detector. Monolithic scintillator detectors with dual-sided DPC readout appear particularly promising for PET applications in which high spatial resolution, high time resolution, and high detection efficiency all are crucial, such as in neurology and pediatric medicine. This work was supported in part by EU FP7

project SUBLIMA, Grant Agreement No 241711 (www.sublima-pet-mr.eu).

OP503

First measurements and Monte Carlo simulations of a BGO-PMTs blocks array intended for continuous energy spectrum tomography in bremsstrahlung imaging

M. Hesse[1], S. Walrand[1], R. Wojcik[2], R. Lhommel[1], F. Jamar[1]; [1]Université Catholique de Louvain, Brussels, BELGIUM, [2]Ray Visions, Inc, Yorktown, VA, UNITED STATES

Rationale: A conventional Anger camera is not adapted to bremsstrahlung imaging: high energy x-rays may fall into the acquisition energy window after scattering in the collimator septa and also in the PMTs after going through the NaI crystal. This increases noise, limits the contrast, and reduces the quantification accuracy. The aim of this study is to experimentally validate previous Monte Carlo (MC) simulations (GateGeant4) showing that using BGO-PMT blocks with a high energy pinhole collimator greatly reduces the scattering contamination and enables the use of an extended energy window ranging from 50 to 400 keV. This would allow the development of a continuous energy spectrum tomography (CET) system. Method: A simple readout board was developed to handle an array of 2x3 BGO-4PMTs blocks coming from a retired PET Exact HR+ (CTI, Knoxville, TN). The energy spectrum of a 137Cs (662 keV) point source was acquired with this simple setup (without collimator or lead shielding). The spectrum was compared to the one simulated by MC (GateGeant4), and to the one acquired using a Triad XLT20 (Trionix, Twinsburg, OH) without collimator, equipped with a ½"-thick NaI crystal. BGO blocks pixelization (4.3x4.0mm pixels, 0.4mm-thick reflecting TiO2 separators) was modelled in the MC simulation while the energy resolution of the BGO-4PMTs block was approximated by a convolution with the sum of 2 Gaussians with energy-dependent FWHM . Results: The readout board was able to clearly identify all the BGO pixels. The energy spectrum acquired with the BGO setup was well reproduced by the MC simulations and displayed a scatter contamination in the [50-400] keV energy window 5 times as low as that obtained with the NaI based conventional camera Triad XLT20. The energy resolution of the BGO setup was measured as 17% at 662 keV.Conclusion: First measurements of the energy spectrum of a 137Cs point source on a simple setup consisting of a 2x3 BGO-4PMTs blocks array, confirm the advantage of BGO crystals over conventional NaI based camera in bremsstrahlung imaging by strongly reducing the scatter contamination in the energy window of interest ([50-400] keV). A dual head mobile CET prototype using a front-plate pinhole collimator is under development. This dedicated bremsstrahlung CET system will enable the dose optimization directly inside the catheterization room during 90Y liver radio-embolization which should result in an improvement of patient outcome.

OP504

Gamma-cube and X-cube: A New Scanner Generation for Benchtop Small Animal SPECT/CT

R. Van Holen, K. Deprez, B. Vandeghinste, S. Vandenberghe; Ghent University, Gent, BELGIUM

The first generation small animal imaging systems offer molecular 3D imaging at sub millimetre spatial resolution with SPECT and sensitivities in the order of several percents using PET. These systems often have a large footprint because they are based on large to medium-size detector technology, adopted from clinical scanners. The next generation of systems aims at (i) improved image quality, (ii) flexibility regarding installation and (iii) ease of operation. Our group has been working on detector hardware and collimator designs to perform SPECT and CT imaging at a footprint of 1/4th of a square meter. Using additive manufacturing of tungsten, lofthole collimators and high-resolution detectors, we have designed and constructed a benchtop microSPECT system. On the other hand, using state-of-the-art CMOS X-ray detector technology, a micro-focal X-ray tube and iterative image reconstruction, we have designed and constructed a benchtop microCT system. SPECT benchmarking has been performed for the general-purpose mouse collimator using performance measurements previously used to objectively determine spatial resolution, sensitivity, uniformity and contrast-to-noise. CT quality control has determined spatial resolution, low-contrast detectability and whole-body mouse imaging time. Results show that SPECT spatial resolution is below 700um measured using a line source. Image reconstruction from a hot-rod resolution phantom separates all rods from 700 micron diameter and larger. Point source sensitivity is above 1200cps/MBq in a simultaneous cylindrical FOV of 3 cm diameter and 1 cm height. Differential uniformity is 23% while contrast to noise curves are in line with current commercial systems' performance. CT imaging at 80um is possible with a soft tissue contrast that outperforms current systems. Whole body imaging of a mouse is possible within 30 seconds, using compressive sensing for dose reduction. All electronics and reconstruction servers are within a cube of 54x54x54cm3 system and the systems can be easily controlled using a tablet or a laptop. The small animal bed supports anesthesia, ECG, respiratory monitoring and heating. It can easily be transferred between both systems to obtain multi-modal SPECT-CT

images. In conclusion, we have developed a SPECT/CT imaging system that is competitive with the state-of-the-art but that can be installed in any certified environment on a table top.

OP505

Left ventricular function assessment using 123I/99mTc dual isotope acquisition with two semi-conductor cadmium zinc telluride (CZT) cameras: a dynamic cardiac phantom study

T. Blaire[1,2], A. Bailliez[1,2], D. Legallois[3], D. Agostini[3], A. Manrique[1,3]; [1]EA 4650, Normandy University, Caen, FRANCE, [2]Nuclear Medicine Department, IRIS, Polyclinique du Bois, Lille, FRANCE, [3]Nuclear Medicine Department, CHU Cote de Nacre, Caen, FRANCE

Objectives: New Cadmium-zinc-telluride (CZT) cameras dramatically increased sensitivity and energy resolution. Combining the use of 123I-metaiodobenzylguanidine with 99mTc myocardial perfusion agents could allow simultaneous assessment of myocardial perfusion, function and sympathetic innervation in patients with dilated cardiomyopathy. This phantom study compared the evaluation of left ventricular function in dual isotope conditions using two CZT cameras (DNM 530c, GE Healthcare and DSPECT, Spectrum Dynamics). Materials and methods: The Amsterdam gated (AGATE) dynamic cardiac phantom (Vanderwilt techniques, Boxtel, The Netherlands) was successively filled with a solution of 123I alone, 99mTc alone, and a mixture of 123I and 99mTc. A total of 24 datasets on each CZT camera were acquired using both energy windows (99mTc or 123I), with the following parameters: 10-minute acquisition, contraction rate of successively 70 and 85 bpm and ejection fraction (EF) set to 33%, 45% and 60%. End-diastolic (EDV), end-systolic (ESV) volumes, ejection fraction (EF), regional wall thickening and motion (17-segment model) were assessed using QGS. A linear model analysis included the effect of camera, acquisition type (single vs. dual isotope) and isotope (123I vs. 99mTc) and the interaction between isotope and camera type. Results: Myocardial volumes using single (123I, 99mTc) and dual isotope (reconstructed using both 123I and 99mTc energy windows) acquisitions were respectively for EDV (mL): 89±24 vs. 89 ±25 vs.91±24 vs. 90±24 for DNM and 64±12 vs. 81±20 vs.73 ±17 vs. 77±18 for DSPECT, ESV (mL): 41±1 vs. 41±1 vs. 42 ±1 vs. 42±1 for DNM and 29±4 vs. 35±2 vs. 31±3 vs. 34±3 for DSPECT, EF (%): 52±12 vs. 51±11 vs. 51±12 vs. 51±11 (p= NS) for DNM and 53±13 vs. 54±12 vs. 55±13 vs. 54±13 (p= NS) for DSPECT, regional thickening (%): 48±21 vs. 46±20 vs. 46±21 vs. 45±20 for DNM and 38±19 vs. 43±19 vs. 43±20 vs. 42±19 for DSPECT, regional motion (mm): 6.8±2.5 vs. 6.6 ±2.4 vs. 6.7±2.5 vs. 6.6±2.4 for DNM and 6.3±2.6 vs. 6.9±2.6 vs. 7.0±2.8 vs. 6.8±2.7 for DSPECT. There was a significant difference between DSPECT and DNM for EDV (p<0,009) and ESV (p<0,001) but not for LVEF (NS), regional motion (NS) or regional thickening (NS). Using the DSPECT, there was a significant difference for ESV between 99mTc and 123I acquisitions (p<0,007). Conclusion: In this phantom study, the two CZT cameras (DNM 530c and DSPECT) yielded significant difference between single and simultaneous dual isotope acquisition for ESV and EDV but yielded no significant difference between LVEF, regional motion and thickening.

OP506

Is there mutual interference between preclinical APD-PET and 3T MR in a sequential configuration ?

J. M. VRIGNEAUD[1], P. M. WALKER[2], B. BARBIER[3], A. CAMACHO[4], A. OUDOT[1], B. COLLIN[1], F. BRUNOTTE[1,5]; [1]Centre Georges-François Leclerc, DIJON, FRANCE, [2]LE2i CNRS UMR 5158, Faculty of Medicine, DIJON, FRANCE, [3]Trifoil Imaging, DIJON, FRANCE, [4]MR Solutions, GUILDFORD, UNITED KINGDOM, [5]LE2i CNRS UMR 5158, Faculty of Medicine, Dijon, FRANCE

AIM: The LabPET®/MRI system is a new preclinical imager with sequentially-acquired PET/MR scans capabilities. The dual modality system is composed of the digital APD-based labPET4 subsystem (Trifoil Imaging), coupled with a cryogen-free superconducting 3.0T MRI subsystem (MR solutions). The objective of the study was to evaluate the performance characteristics of each subsystem to identify the presence of mutual interference between the two modalities. MATERIALS AND METHODS: For the PET subsystem, NEMA NU-4-2008 performance characteristics were conducted with static magnetic field switched on (ON) and off (OFF). The following tests were performed: spatial resolution, counting-rate performance, scatter fraction, sensitivity and image quality. A Jaszczak phantom was also acquired at three different activity levels. For the MR subsystem, machine performance was evaluated with the PET subsystem electronics ON and OFF, as well as a third configuration in which the two subsystems were uncoupled. Gadolinium-doped flood field and resolution phantoms were used, and tests were carried out using a standard T1-weighted sequence with TR/TE 1000/20ms, matrix 256x256, FoV 40mm, slice 1mm. SNR, non-uniformity, circularity, ghosting, spatial resolution and phase/frequency profiles were quantified. RESULTS: For the PET subsystem, no significant differences were identified between the ON and OFF configuration for the spatial resolution, Jaszczak phantom and counting rate performance tests. However, peak absolute sensitivity was found to be 0.87% in the ON configuration versus 0.93% in the OFF configuration and sensitivity performance was decreasing with increasing ambient

temperature. Using the NEMA phantom, image uniformity was 7.9%/7.5% and spill-over ratios of 13.1%/14.2% and 24.0%/24.3% were obtained in water and air (ON/OFF). For the MR subsystem, no significant differences were observed among the experimental conditions. SNR was 49.7±0.5, image signal non-uniformity 6.0±0.1%. and the ghosting coefficient 0.0025±0.0001. No differences in phase/frequency profiles were observed. CONCLUSION: Whereas APD are known to be insensitive to magnetic field variations, their gain factor exhibits a strong dependence with temperature. In the operating configuration of the LabPET®/MRI system (ON), there is a slight increase in ambient temperature (+1°C) compared to the LabPET in the OFF configuration. This slight difference might explain the observed PET sensitivity variation of up to 6% when the PET detectors are in the same calibration state. Irrespective of the experimental conditions, the performance of the MRI subsystem did not appear to be altered by the physical and electrical presence of the PET subsystem.

OP507

Design of an Optimized Multi-pinhole Collimator for Brain SPECT

L. Chen, **G. S. Mok**; University of Macau, Taipa, MACAO

Aim: SPECT imaging on dopaminergic system is a powerful tool for diagnosing and staging Parkinson's disease (PD). Since pinhole SPECT provides superior trade-off between resolution and detection efficiency as compared to conventional low energy high resolution (LEHR) parallel-hole collimator for imaging small field-of-view (FOV), we propose to develop and evaluate a multi-pinhole (MPH) collimator for PD brain imaging based on a clinical SPECT/CT scanner. Materials and methods: We set the target resolution to be 7.27 mm which is the same as the resolution of LEHR at imaging distance of 10.5 cm, and the FOV was set to be 12 cm which is large enough to cover the whole striatum and substantia nigra region. The constraints for system optimization include maximum and minimum detector to center-of-FOV (CFOV) distances for the scanner which were 34.5 cm and 13 cm respectively, and the maximum and minimal imaging distances which were 34 cm and 12.5 cm respectively. Based on the work from Nillius *et al*. and the system constraints, we optimized the detection efficiency and calculated the design parameters. All pinholes were knife-edge and tilted to the CFOV. We then evaluated the imaging performance of the MPH and standard LEHR collimators using the digital Human Brain Phantom and analytical simulations. One hundred and twenty-eight noise-free projections were generated using 3D MPH/LEHR projectors over 360 degrees and reconstructed using the 3D MPH/LEHR OS-EM method with up to 300 updates. Normalized mean square errors (NMSE) were measured over the putamen region on the reconstructed images as compared to the original phantom. Results: The optimized design parameters were 20 pinholes with aperture size of 3.6 mm, acceptance angle of 56.4 degrees, 14.8 cm collimator length and 12.7 cm imaging distance. The detection efficiency of the proposed 20 pinholes collimator had 663% improvement as compared to the LEHR collimator. Simulations showed that there were no substantial artifacts observed in the MPH images and the putamen region can be clearly delineated. The NMSE for the MPH noise-free reconstructed images was comparable to that of the LEHR. Conclusion: The MPH collimator can provide six-fold detection efficiency at the same resolution compared with LEHR collimator, which can be traded for reduced acquisition time or lower injection dose. MPH SPECT for brain imaging is feasible and has the potential to improve PD diagnosis.

OP508

Design of shields for counting Cr-51 EDTA plasma samples from patients having a Tc-99m imaging study on the same day

N. Bird, D. Gillett; Addenbrooke's Hospital, Cambridge, UNITED KINGDOM

Aim: Patients are often referred for both a GFR and either a MUGA or a DMSA study. Currently, if both studies are performed on the same day, either the 4 hour GFR test with Cr-51 EDTA is completed before injecting the Tc-99m radiopharmaceutical or the two studies are performed concurrently and the plasma samples for the GFR are left for a few days for the Tc-99m to decay before counting. This is because a high activity of Tc-99m in the samples causes pileup into the Cr-51 window. The aim of this study was to devise a method whereby the two studies can be performed concurrently and the plasma samples counted the same day. Methods: Plasma samples from patients were analysed to determine the maximum Tc-99m activity likely to be present in samples when counted. Shields were designed to surround the counting tubes to sufficiently attenuate the 140 keV gammas to prevent pileup and dead-time problems, whilst limiting the reduction in sensitivity for 320 keV gammas from Cr-51. When using the shields the counting time was optimised so there should be no increase in uncertainty from counting statistics. 12 Samples from patients containing both isotopes were counted with the shields and after allowing the Tc-99m to decay. Results: The maximum Tc-99m activity found in the plasma samples was 10 kBq. It was determined that optimally shields would be made from 1 - 1.5 mm of lead. A set of 1.5 mm thick lead shields were made, the transmission for Cr-51 is 44 % and for Tc-99m is less than 1.5 %. These were found to be sufficient to eradicate the problem of pileup from up to 40 kBq of Tc-99m.

There was no increase in uncertainty from counting statistics when using the shields when counting time was increased to 5000 seconds per sample from 1500 seconds. There was good agreement between the concentrations of Cr-51 measured with shields and after decay of the Tc-99m.ConclusionUsing the shields makes it possible to count plasma samples for Cr-51 EDTA containing Tc-99m from other imaging tests without compromising the GFR test results. This has the advantage of reducing the time that patients need to remain in the Nuclear Medicine department without compromising how soon results are available. This can be particularly important in cancer patients being worked up for chemotherapy.

Blunted striatal dopamine release in cannabis dependence

E. van de Giessen[1,2], J. Weinstein[1], C. Cassidy[1], M. Haney[1], M. Slifstein[1], A. Abi-Dargham[1]; [1]Columbia University College of Physicians and Surgeons/New York State Psychiatric Institute, New York, NY, UNITED STATES, [2]Academic Medical Center, Amsterdam, NETHERLANDS

Aim: The active component of cannabis (THC) induces a dopamine release in the striatum. Dependence on other dopamine enhancing substances of abuse is associated with blunted striatal dopamine transmission. The aim of this study is to measure striatal dopamine release capacity in a carefully selected sample of severely cannabis dependent (CD) subjects, who did not use other substances of abuse (including nicotine) and had no other major psychiatric illnesses. Materials and Methods: Eleven CD subjects and twelve healthy control (HC) subjects completed two positron emission tomography scans with [^{11}C]-(+)-PHNO, before and after oral administration of d-amphetamine. Percent change in [^{11}C]-(+)-PHNO binding after amphetamine (change in nondisplaceable binding potential, ΔBP_{ND}) was compared between groups. CD subjects stayed inpatient for 5-7 days prior to the PET scans to control abstinence. Correlations with psychopathological and neurocognitive parameters were examined. Results: CD subjects used marijuana for 29.1 ± 3.6 days during the month prior to inpatient admission and used an estimated 79.2 ± 72.7 grams during this month. CD subjects had significantly lower ΔBP_{ND} in the striatum (CD: -18.4 ± 4.3%, HC: -24.9 ± 4.5%, p = 0.002, effect size 1.48), specifically in the associative striatum (CD: -14.6 ± 4.1%, HC: -21.1 ± 5.2%, p = 0.003) and sensorimotor striatum (CD: -24.9 ± 6.1%, HC: -32.3 ± 4.2%, p = 0.003), and in the globus pallidus (CD: -13.0 ± 6.8%, HC: -22.6 ± 9.5%, p = 0.012, effect size 1.16). Lower dopamine release in the associative striatum correlated with more negative symptoms and higher inattention scores in CD subjects and with poorer working memory and probabilistic category learning performance in both CD and HC subjects. Conclusion: Striatal dopamine release is lower in the associative striatum and sensorimotor striatum in severely cannabis dependent subjects with no psychiatric comorbidities including any other substance abuse. The lower dopamine release in the associative striatum is related to more psychopathology and reduced neurocognitive performance in cannabis dependence.

OP510

Effect of chronic social defeat on neuroinflammation in rats: a PET imaging study with [11C]PK11195

P. Kopschina Feltes[1], E. F. J. de Vries[1], C. M. Moriguchi Jeckel[2], E. Kurtys[1], P. Michel[1], R. A. J. O. Dierckx[1], J. Doorduin[1]; [1]University of Groningen, Groningen, NETHERLANDS, [2]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre, BRAZIL

Aim: Stressful life events are considered to be predisposing factors for the onset of psychopathologies such as anxiety and depression. Psychosocial distress may disrupt fundamental interactions between the immune system and the brain, ultimately leading to mood and behavior alterations. In this context, it is hypothesized that chronic stress might trigger neuroinflammation. The present study evaluated whether repeated social defeat leads to neuroinflammation, using PET imaging. Methods: From day 0-4 of the experiment, 8 weeks old male Wistar rats (intruders) were placed in the home cage of an aggressive dominant male Long Evans rat (resident) for a total of 60 minutes each day. The intruders were attacked and defeated by the residents as indicated by adopting a submissive posture for at least 3 seconds. For the remaining time after submission, the intruders were placed in a wire-mesh cage. Control rats were exposed to a new cage without a resident, considering the same time points as their experimental counterparts. Behavioral alterations were assessed through a sucrose preference test at a concentration of 1% and an open field test, on day -2 and 5. On the 11th experimental day, an i.v. injection of [^{11}C]PK11195 was performed, followed by a 30-min static small animal PET scan 45 min after injection. Differences between groups were tested using an independent samples t-test on the standardized uptake value obtained from volume of interest analysis. Within subject differences in behavioral tests were tested through a paired t-test. A p-value <0.05 was considered statistically significant. Results: On day 5, the percentage of preference for sucrose solution was significantly decreased (21%, p<0.001) in defeated rats, whereas no difference was found in control rats. In the open field test, defeated rats had a significantly lower total distance

moved (32%, p<0.001), while no statistical difference was found in the control group between day -2 and 5. An increase in uptake of [^{11}C]PK11195 was found in the orbitofrontal cortex (33%, p=0.006), cerebellum (26%, p=0.032), insular cortex (22%, p=0.016), medial/prefrontal cortex (21%, p=0.007) and hippocampus (21%, p=0.047) of defeated rats on day 11, when compared to control rats. Conclusion: Repeated social defeat resulted in depressive-like behavior. In addition, neuroinflammation, as shown with [^{11}C]PK11195 PET, was found in brain regions associated with depression. These results suggest that neuroinflammation can arise from chronic exposure to stress.

OP511

Dopamine transporter availability in alcohol-dependent patients before and after deep repetitive transcranial magnetic stimulation: a ^{123}I-FP-CIT Study

D. Di Giuda[1], F. Cocciolillo[1], I. Bruno[1], I. Marini[1], M. Zollino[1], A. Ferrulli[2], M. Antonelli[2], G. Vassallo[2], A. Mirijello[2], G. Addolorato[2], A. Giordano[1]; [1]Nuclear Medicine Institute, Università Cattolica del Sacro Cuore, Roma, ITALY, [2]Internal Medicine Institute, Università Cattolica del Sacro Cuore, Roma, ITALY

AIM: Experimental and neuroimaging studies suggest a striatal dopaminergic dysfunction in alcohol dependence. Repetitive transcranial magnetic stimulation (rTMS) is a new and promising treatment for substance addiction. Preliminary data in alcohol-dependent patients showed that rTMS of the dorsolateral prefrontal cortex increases dopamine release in the striatum, reducing craving. We assessed DAT availability in actively drinking alcoholics before and after deep rTMS by ^{123}I-FP-CIT SPECT, investigating changes in DAT levels and clinical parameters. MATERIALS & METHODS: We enrolled 14 untreated patients (12 M, mean age: 49 ± 10 years) with a DSM-IV diagnosis of alcohol dependence in an active drinking phase and without a major psychiatric disorder. After baseline SPECT scan, 11/14 patients were randomised to a real rTMS (n=5) or a sham stimulation (n=6). Each patient underwent 12 rTMS sessions for one month and a second SPECT scan was carried out at the end of treatment. Severity of alcohol dependence and craving were assessed before and after rTMS with the Alcohol Dependence Scale, Penn Alcohol Craving Scale and Obsessive Compulsive Drinking Scale. Anxiety and depression were evaluated by the State-Trait Anxiety Inventory and Zung Depression Self-Rating Scale. The alcohol Timeline Follow-back (TLFB) was used to estimate daily drinking. A ^{123}I-FP-CIT template was generated with images of 20 healthy subjects (HS, 12 M, mean age: 47±16 years). Patient scans were spatially normalised to the ^{123}I-FP-CIT template by SPM8. The analysis was performed using VOIs selected from a digital atlas; VOI mean activity concentration was obtained through the Marsbar toolbox and Specific Binding Ratios (SBRs) were calculated in the caudate nuclei and putamina. RESULTS: At baseline, alcoholics showed higher SBRs in the caudate nuclei and putamina (p<0.05) in comparison with HS. An inverse correlation was found between SBR in the left caudate and anxiety levels (p<0.05). After treatment, patients submitted to real rTMS had a reduction in SBRs and differences were no longer detected in comparison with HS. Conversely, patients undergoing sham stimulation showed higher SBRs compared with HS (p<0.05) also in the SPECT scan after treatment. When considering TLFB data, a significant reduction in alcohol intake (p<0.05) was detected only in patients submitted to real rTMS. CONCLUSION: Our preliminary data show that striatal DAT availability was increased in alcohol-dependent patients, supporting the assumption of a dysfunctional dopaminergic system. Notwithstanding the small sample, an SBR "normalization" and a reduction in alcohol intake after real rTMS could suggest clinical efficacy of deep rTMS.

OP512

Regional cerebral blood flow changes in acute and transient psychotic disorders

R. Petrovic[1], A. T. Golubic[1], M. Rojnic[2], T. Samardzic[1]; [1]Department of Nuclear Medicine and Radiation Protection, University Hospital Center Zagreb, Zagreb, CROATIA, [2]Clinical Department of Psychiatry, University Hospital Center Zagreb, Zagreb, CROATIA

Aim: The aim of this study was to assess and evaluate brain perfusion single-photon computerized tomography (SPECT), as part of a continuing effort to understand the pathophysiology of the brain in acute and transient psychotic disorders (ATPD) and to correlate any abnormalities in the regional blood flow with psychopathology of these disorders. They present as an acute psychosis associated with acute stress, with sudden onset and polymorphous symptomatology, including psychotic symptoms such as hallucinations and delusions. Method: Twenty (11 male, 55%) newly referred patients with an ATPD diagnosis underwent regional cerebral blood flow (rCBF) examination brain SPECT. Their mean age was 30.5 years, range 18-52. Brain rCBF SPECT data from age- and sex-matched healthy volunteers were used as controls. Patients were diagnosed following ICD-10 criteria and were off psychoactive medication. SPECT scans were started 30 minutes after administration of 740 MBq of 99mTc-HMPAO in resting state, eyes closed and with low ambient noise. Tomograms were normalized to the mean brain activity and analyzed visually by two independent observers, unaware of clinical diagnosis. Results: Majority of our patients, 85%, had brain

perfusion changes, from small regions of decreased perfusion to widespread global cortical hypoperfusion and disseminated cerebral blood flow defects. Seven patients had globally hypoperfused cerebral cortex. In four patients hypoperfusion was found exclusively in only one region, three left frontal, 1 right temporal. Thirteen patients (76%) had two or more hypoperfused areas, 11 in the prefrontal lobes (55%), mostly in the left lobe (n=6) and bilaterally (n=4). Seven patients had hypoperfusion reported in temporal lobes, four in the right hemisphere and two bitemporal. Additional, detailed neurologic and laboratory examinations, including EEG and CT, were within normal limits in all patients. Conclusions: Compared with the normals, majority of patients with ATPD were characterized by abnormal rCBF, predominantly affecting prefrontal cortex and the temporal lobes, and, in some cases, whole cerebral cortex. Different factors might explain areas of decreased rCBF, in part as the consequence of neurophysiological changes which reflects dysfunction in neuronal activity responsible for psychotic symptoms such as hallucinations and delusions, and/or the result of some associated symptoms such as associated acute stress. However, perfusion imaging findings may be used as an additional diagnostic tool to guide psychiatrists searching for a definite diagnosis.

OP513

Pedophilia and Child Sexual Abuse: Evidence for Altered Serotonergic Function in Pedophilic Offenders

G. Berding[1], G. Tenbergen[2], F. Wilke[3], F. Paesler[1], L. Geworski[3], F. M. Bengel[1], T. H. C. Kruger[2]; [1]Department of Nuclear Medicine, Hannover Medical School, Hannover, GERMANY, [2]Clinic of Psychiatry, Socialpsychiatry and Psychotherapy, Hannover Medical School, Hannover, GERMANY, [3]Department of Medical Physics and Radiation Protection, Hannover Medical School, Hannover, GERMANY

Aim: Altered serotonin transporter (SERT) function has been demonstrated in subjects with higher impulsivity [1,2]. Reduced SERT function has been described in anxiety and depression disorders [3,4], which are typically associated with risk avoidance. The purpose of this study was to test the hypothesis of altered SERT function and impulsivity in paedophilic patients with histories of Child Sexual Abuse (CSA). Materials and methods: In this study 26 paedophilic patients (11 with CSA, 15 without) and 17 age matched healthy control subjects were enrolled. In each patient anxious and depressive symptoms were rated with the Hamilton Anxiety Scale (HAM-A) and Hamilton Depression Scale (HAM-D). To assess impulsive decision-making, the Information Sampling Task (IST) from the Cambridge Neuropsychological Test Battery (CANTAB) was used. I-123-ß-CIT SPECT (using a dual head SPECT/CT) was performed 4 hours post injection for measurement of SERT. Data was spatially normalized based on a template in Talairach space. Volumes of interest from the WFU pick-atlas were used to extract counts in regions with specific binding (thalamus, hypothalamus, midbrain and pons) and a cortical reference region for calculation of binding ratios. Results: SERT binding ratios for the midbrain region in paedophilic patients with CSA (2.00±0.12) were significantly (p=0.0477) elevated compared to the control subjects (1.88±0.14). In patients without CSA none of the regions SERT binding ratios were significantly different compared to control subjects. In patients with CSA a significant negative correlation between SERT binding in the thalamus and HAM-A score (r=-0.90, p=0.0001) as well as HAM-D score (r=-0.82, p=0.0022) was observed. Furthermore, a significant positive correlation between SERT binding in the pons and errors in the IST was found (r=0.64, p=0.0343). Conclusion: Our data indicate that increased SERT binding might be a characteristic of paedophilic offenders against children. Increased SERT binding in these patients was especially associated with fewer anxiety symptoms on the HAM-A and more impulsive decision-making as measured by the IST. These findings underline the relevance of the serotonergic system in paedophilia and child sexual abuse. References[1] Lesch et al. (2000) Behavioral Sciences and the Law, 18:581-604. Altered Regional Cerebral Blood Flow in Chronic Whiplash Associated Disorder

D. Vállez Garcia[1], A. Otte[2], A. T. M. Willemsen[1], R. A. J. O. Dierckx[1], J. Doorduin[1], G. Hostege[3]; [1]University Medical Center Groningen, Groningen, NETHERLANDS, [2]Offenburg University of Applied Sciences, Offenburg, GERMANY, [3]University of Queensland, Brisbane, AUSTRALIA

Aim: Whiplash trauma in one of the most frequent consequences of motor vehicle accidents. While initial symptoms resolve within a few weeks in many cases, some patients develop persistent symptoms that include pain, headache, visual, and/or psychological disturbances, termed as Whiplash-associated disorder (WAD). Although there is evidence supporting tissue lesion and central hyperexcitability, the pathophysiology is not well understood. In the current study, possible alterations in the regional cerebral blood flow (rCBF) were explored with PET imaging. Material and Methods: Twelve female patients diagnosed with WAD grade I/II were included 5±2 years after the accident, in addition to eight healthy matched volunteers. PET scans (ECAT HR+, Siemens) were acquired after injection of 500 MBq [15O]H2O for rCBF measurement. During acquisitions the

volunteers received a non-painful electrical stimulation of the neck (DS7A, Digitimer). Sensitivity thresholds were individually determined. Four condition were used: rest state, placebo-like state (current was expected but not generated), stimulation above perception threshold, and stimulation below pain or muscular contraction. These conditions were repeated three times, resulting in twelve scans. All participants completed a neurological interview, the Hospital Anxiety and Depression Scale, the Neck Disability Index (NDI), the Whiplash Disability Questionnaire, and rated pain on the visual analogue scale. Voxel-based analysis was performed on the scans with SPM8 in combination with SwE toolbox to account for repeated measurements. Level of significance was set to $p<0.005$ uncorrected, with an extent threshold of 100 voxels. Correlations between the rCBF of WAD patients in the significant clusters and the scores from questionnaires were analyzed using the Generalized Estimating Equations model in SPSS, with $p<0.05$ considered significant (Bonferroni-Holm). Results: In all the questionnaires WAD patients scored higher ($p<0.001$) than healthy volunteers. No significant differences in rCBF were found between conditions. In WAD patients, compared with healthy controls, a significant increase in the rCBF was found in the right superior parietal gyrus (T=3.52±0.51). In addition, a decreased rCBF was found in the left insula (T=3.66±0.72), right insula (T=3.62 ±0.68), and right thalamus (T=3.54±0.47). Within the WAD group, a negative association ($p<0.02$) was found in these regions between NDI scores and rCBF. Conclusion: WAD symptoms might be the result of a mismatch between the proprioceptive information from the cervical spinal cord and the information integrated in regions such as mesencephalon, thalamus and insula. Further investigation of the functional brain alterations present in WAD patients must, however, be performed for a better understanding of the pathophysiology.

OP515

Genetic influences in FDG uptake in precuneus and posterior cingulate cortex: a PET study in non-demented twins

S. Watanabe[1], H. Kato[1], E. Shimosegawa[2], J. Hatazawa[1], Osaka Twin Research Group; [1]Department of Nuclear Medicine and Tracer Kinetics, Osaka University Graduate School of Medicine, Suita, Osaka, JAPAN, [2]Department of Molecular Imaging in Medicine, Osaka University Graduate School of Medicine, Suita, Osaka, JAPAN

Purpose: The Alzheimer disease (AD) is the most common dementia. It is known as a multifactor disease, and many factors including genetic and environmental factors have been reported to be concerned in the onset of the disease. FDG-PET studies have been revealed the characteristic glucose metabolic patterns; decreased metabolism especially in precuneus and posterior cingulate cortex, even in the early stage of the disease. Some previous FDG-PET studies targeting for discordant (demented and non-demented) twin pairs reported reduced glucose metabolism in the non-demented co-twins, suggesting preclinical pathogenesis or contribution of genetic factors. We investigated whether genetic influences were observed in glucose metabolism in precuneus and posterior cingulate cortex using clinically non-demented concordant twins including young and middle aged subjects, and attempted to quantify the genetic and/or environmental influences. Methods: This research was carried out as a part of the twin research of our institution. FDG uptake was studied in 59 pairs of right-handed volunteer twins (41 monozygotic pairs (mean age 60.4 ± 11.9 years, age range 35-88 years) and 18 dizygotic pairs (mean age 64.9 ± 15.4 years, age range 32-85 years)) aged 30 years or over. The brain PET images were analyzed by voxel-based statistical analysis with automated region-of-interest setting. The mean FDG uptake in precuneus and posterior cingulate cortex was semi-quantified. We first referred Mini Mental State Examination (MMSE) scores and compared the scores with the regional glucose metabolism. Next, structural equation modeling (SEM) was applied to investigate the degrees of genetic, shared environmental, and unique environmental influences on the regional FDG uptake. Results: Although all the subjects were independent in the daily life, the MMSE scores were ranged between 22 and 30. However, no apparent differences in FDG uptake in precuneus or posterior cingulate cortex were observed between low MMSE score subjects and high MMSE score subjects. The SEM estimated genetic contribution to regional FDG uptake as 0.39 (95%CI: 0.11-0.66) in left precuneus, 0.28 (however, 95%CI of genetic parameter estimate include 0) in right precuneus, and 0.30 (95%CI: 0.25-0.66) in right posterior cingulate cortex, while common environmental rather than genetic influences were indicated in left posterior cingulate cortex (the relative importance was estimated as 0.43 (95%CI: 0.19-0.78).). Conclusion: We demonstrated not only environmental but also genetic contributions to the FDG uptake in precuneus and posterior cingulate cortex even in younger non-demented subjects, suggesting the essential genetic influence in these regions.

OP516

Decreased frontotemporal cerebral blood flow in congestive heart failure.

C. Pascovich[1], R. García[2], A. Damian[1], M. Langhain[1], E. Angarita[2], R. Ferrando[1]; [1]Nuclear Medicine Centre, Clinical Hospital, University of the Republic, Montevideo, URUGUAY, [2]Fundación Cardiovascular de Colombia., Bucaramanga, COLOMBIA

Background: Congestive heart failure (CHF) is one of the major public health problems with great impact on mortality and morbidity. Studies have shown that patients with CHF have cognitive impairments. Cerebral hemodynamic changes resulting from decreases in left ventricular ejection fraction (LVEF) as well as brain microinfarctions secondary to microembolisms could be underlying mechanisms. Reduced oxygen levels may cause neurotoxicity, particularly in certain areas more vulnerable to hypoxia like hippocampus, amygdala, frontal lobes and cerebellum. Aim: To evaluate the presence of regional cerebral blood flow decreases in patients with CHF.Materials and methods60 patients with CHF (42-82 years, mean 65.4±9.8; 38 male; functional class I-IV; LVEF 10-68%, mean 33.7±15.7%) and 40 normal controls (32-89 years, mean 61.9±16.4, 18 male) were evaluated using brain SPECT with 99mTc-ECD. Groups did not differ significantly in age and gender. Previous neurological or psychiatric pathology was excluded. Image analysis was performed in SPM8. Clusters greater than 100 volxels with $p<0.01$ FWE corr at the voxel level were reported ($p<0.001$ uncorr was considered if no results were found). Subsequent comparisons were performed excluding patients with ischemic heart disease (39/60) and possible depression (antidepressant medication or elevated CES-D scores) (10/60). Possitive correlations with LVEF and negative correlations with duration of the CHF were also assessed. Results: Patients with HCF showed extensive bilateral frontal hypoperfusion. Anterior temporal poles, midbrain and pons were also affected. Frontal, temporal and pontine changes remained after excluding patients with ischemic heart disease and possible depression. LVEF correlated positively with bilateral superior frontal perfusion. Negative correlation with duration of CHF showed a trend to statistical significance in dorsal frontal and posterior parietal cortex ($p<0.01$ uncorr). Conclusions: Patients with CHF have extensive frontal hypoperfusion as well as anterior temporal and brain stem hypoperfusion. Frontal changes correlated positively with LVEF. These findings are probably the result of chronic brain hypoxia due to CHF and can not be explained only by depression or atherosclerotic cerebrovascular disease. The results provide a neural basis for the presence of cognitive impairment in CHF, as frontal and temporal function is crucial for memory, attention and executive performance.

The so-called thyroid stunning effect: quantitative radiobiological analysis and prediction of the remnant control probability.

S. Walrand, M. Hesse, F. Jamar; Université Catholique de Louvain, Brussels, BELGIUM

Aim: The origin of the reduction in thyroid uptake after a low activity iodine scan, so-called stunning effect, is still controversial. Two explanations prevail: an individual cell stunning that reduces its capability to store iodine without altering its viability or a significant cell killing fraction that reduces the number of cells in the tissue still taking up iodine. Our aim is to analyze whether this last assumption could quantitatively explain the observed reduction. Methods: a general expression of the cell survival fraction as a function of the mean absorbed dose was derived from the dose volume histogram measured in thyroid metastases by ^{124}I PET. Afterwards, the survival fractions were computed for ^{124}I, ^{131}I and ^{123}I using the radiosensitivities of normal and tumor human thyroid cell assays reported in the literature. Results: the computed survival fractions were in line with the uptake reduction observed after a 2 mCi 131I scan by Lassmann et al. (2004) and observed after a 5 mCi ^{123}I scan by Hilditch et al. (2002), as well. Contrary to a commonly accepted opinion, small absorbed dose, about 15 times lower than those delivered for ablation, already kill a significant fraction of cell. This results from the Poisson statistics governing the tissue control probability (TCP) (Brahme and Agren 1987). As a result the control a few grams of tissue requires high absorbed dose providing survival fraction lower than 10^{-9}. This feature was experimentally observed in megacolony cell assay (Kappler et al. 2007). Furthermore, the computed TCP quantitatively explained the administered activity needed for thyroid remnant ablation. Conclusion: The quantitative radiobiological analysis, based on radiosensitivities measured in thyroid cell assays, shows that the uptake reduction effect can be purely explained by the cell killing fraction. This supports the non-existence of an individual cell stunning effect that, if present, should induce an additional uptake reduction resulting in much larger decreases than those observed. The study shows that the three radioiodines isotopes (i.e. ^{124}I, ^{131}I, ^{123}I) induce a significant uptake reduction after a low activity scan. As the β/α ratio is very low, this effective fractionation of the therapy should not impact the patient outcome in agreement with recent studies. As a result, a pretherapeutic dosimetry study makes sense in order to optimize the administered activity in function of the uptake of the thyroid remnants that is highly patient dependent.

OP524

Measuring the radiation dose to the thyroid with a simple collar detector system in patients with radionuclide therapy; A feasibility study

P. Brinks, D. B. M. Dickerscheid, E. Kranenborg, J. Lavalaye, J. B. A. Habraken; St. Antonius hospital, Nieuwegein, NETHERLANDS

An important parameter for successful treatment of thyroid diseases with I-131 radionuclide therapy is the radiation dose delivered to the thyroid. To obtain the desired radiation dose, the administered patient-activity is calculated using thyroid uptake values, determined from pre-therapeutic uptake measurements of I-123. The actual radiation dose to the thyroid with therapy can be determined by measuring the activity in the thyroid at various time intervals after administration of the therapeutic dose of I 131, using gamma camera imaging. Because transporting the patient to the nuclear medicine facility is challenging (from a radiation safety point of view) and repeated measurements are time-consuming, the actual radiation-dose is typically not determined. We present a simple device that consists of a collar with a special dosimeter placed around the patient's neck, designed to continuously measure the activity of I-131 in the thyroid. Uptake can be measured without transporting the patients and repeated use of expensive diagnostic setups is also not required, thereby enabling the possibility to measure the actual delivered radiation dose in a simple and effective manner. The collar therapy indicator (CoTI) device, fabricated by AG Medical, contains up to 4 independent gamma radiation detectors, of which two are placed in a collar that is positioned around the patient's neck. The detectors are based on single Silicon Photo-Multiplier devices with a CsI(Tl) scintillation crystal. Data are temporarily stored on a lightweight and portable control unit and sent via a wireless connection to a tablet for storage and display. We present a feasibility study of CoTI for measuring the delivered radiation dose to the thyroid for I-131 radionuclide therapy patients. To demonstrate the working principle of CoTI for thyroid uptake measurements a comparison study between CoTI and a Siemens ECAM camera was performed, involving 20 patients. The results provided a good correlation between the two different methods, as confirmed by the obtained R2 value of 0.87, which clearly demonstrates the working principle of CoTI for thyroid uptake measurements. Additionally, we will present measurements of the uptake curve during I-131 radionuclide therapy. These results can be used to calculate the effective half-life and the actual radiation dose, assisting in the evaluation of radionuclide therapy. In conclusion, a new measurement device that is embedded in a collar around the patient's neck is presented. This device can be used to continuously measure the thyroid iodine uptake and thereby the radiation dose delivered during I-131 radionuclide therapy.

OP525

Relationship between circulating anti-thyroglobulin antibody (TgAb) and tumor metabolism in patients with Differentiated Thyroid Cancer (DTC): diagnostic and prognostic implications

E. Pomposelli[1], F. Pupo[2], I. Calamia[1], G. Ferrarazzo[1], G. Pesce[2], F. Fiz[1], G. Bottoni[1], M. Giusti[3], G. Sambuceti[1], M. Bagnasco[2], S. Morbelli[1]; [1]Nuclear Medicine Unit, IRCCS San Martino - IST, University of Genoa, Genoa, ITALY, [2]Autoimmunity Unit, IRCCS San Martino - IST, University of Genoa, Genoa, ITALY, [3]Endocrinology Unit, IRCCS San Martino - IST, University of Genoa, Genoa, ITALY

TgAb concentrations respond to changes in the mass of Tg-secreting thyroid tissue. It has been suggested that TgAb concentration may have clinical value as surrogate DTC tumor-marker. Recent evidence suggest a link between TgAb titers and DTC aggressiveness. DTC metabolism as assessed by 18F-FDG PET is a well-recognized prognostic indicator. AIM: to evaluate the relationship between TgAb levels and tumor glucose metabolism in patients with DTC. Methods: 71 patients with DTC who underwent 18F-FDG PET/CT scan were included in the present study. Indications for PET were negative iodine-131 whole-body scan and elevated TgAb level or restaging in high risk patients for diagnostic and prognostic purposes. Radioiodine avidity of DTC lesions was established on the bases of recent patients' history (post-therapeutic 131I scan was available for all patients). TgAb levels were measured with ELISA within 15 days from FDG-PET scan. On the bases of the results of FDG-PET, post-therapy 131I scans and Tg levels, patients were divided in two groups according to the evidence (ED) or absence (NED) of disease. ED patients were further divided in three subgroups: 1. radioiodine avid with positive FDG PET (PET+/131I+). 2. Radioiodine refractory with positive FDG PET (PET+/131I-) 2. Radioiodine avid with negative FDG-PET (PET-/131I+). Mean standardize uptake values of all FDG-avid lesions was assessed and averaged for each patient. T-test was performed to assess the difference between TgAb levels in ED and NED patients as well as between NED patients and PET+/131I+, PET+/131I- and PET-/131I+ subgroups independently. Linear regression was performed to assess relationship between TgAb on one side and SUVmean in the three subgroup of ED patients on the other. Results: TgAb levels (IU/L) were: 33 (range 9-117) in NED and 37 (range 2-416) in ED patients (p=ns); however this value raised to 94 (range 79-416) in PET+/131I+ subgroup ($p<0.003$ with respect to NED) while was significantly lower in PET+/131I- subgroup (24 IU/L; $p<0.04$ versus NED). Only one patient belonged to PET-/131I+ subgroup (Tgab were 47 IU/L). Finally, only in PET+/131I+ subgroup, SUVmean was directly correlated with TgAb levels (R2=0.76). Conclusions: Significantly higher TgAb in radioiodine avid DTC with positive FDG-PET support the role of TgAb levels as surrogate tumor marker in DTC patients (at least when radioiodine avidity and thus Tg-secretion is preserved). The correlation with tumor metabolism suggests that increased TgAb level may also have prognostic implications in the follow-up of DTC patients.

OP526

The Survival and Outcome of Recurrent Differentiated Thyroid Carcinoma: Results of a Long-Term Follow-up Study

J. Mihailovic, E. Matovina, N. Klicov; Oncology Institute of Vojvodina, Sremska Kamenica, SERBIA

Aim: To analyze the survival and outcome of recurrent differentiated thyroid carcinoma (DTC) treated with I-131. Patients and methods: Among 351 DTC patients treated with I-131 between 1977-2000, we analyzed 99 patients with recurrent disease (RD)(74 females, 25 males; 41 patients <45 years, 58 patients ≥45 years); median follow-up=12 years (range,1-39yr); 27 follicular, 70 papillary carcinomas and 2 undetermined histology; TNM stage I, II, III and IV included 4, 7, 24 and 48 patients, respectively while 16 patients were not staged. Initial nodal metastases (N1), distant metastases (M1) and combined metastases (N1M1) were presented in: 39, 53 and 1 patients, retrospectively, while 58 patients initially had no metastases (N0M0). Disease specific survival was analyzed by Kaplan-Meier method. Results: Among 351 DTC, RD was detected in 99 (28.2%) patients, median time of appearance was 67 monhts (range, 6-272 months). Recurrences were treated by RAI in 31 pts; surgery (S) in 9 pts, S+RAI in 38 pts; chemotherapy (CH) was performed in 1 patient; S+CH+external beam radiotherapy (EBRT) in 2 pts; CH+RAI in 2 patients; EBRT+S+RAI was performed in 9 pts; EBRT+S in 2 patent and EBRT+RAI in 1 patient; in 4 patients recurrences were not treated. At last check up, out of 99 patients with RD 49 (49.5%) patients were alive, 41 (41.4%) patients died due to disease related deaths, and 9 (9.1%) patients died from other causes. The 5-, 10-, 20- and 39-year disease specific survival was: 0.904 ±0.30; 0.756±0.46; 00.525±0.62, and 0.287±0.126, respectively. Conclusion: Careful monitoring of DTC patients is necessary for detection and treatment of recurrence. Patients with recurrent disease have worse

prognosis than those without recurrence, but may be cured if treated on time and properly (surgery with additional RAI, if necessary).

OP527

The effect of post-ablation 131I SPECT/CT on the staging and initial risk-stratification of children with differentiated thyroid cancer

B. Liu, R. Tian; Department of Nuclear Medicine, West China Hospital, Sichuan University, Chengdu, CHINA.

Purposes: Over the past decade, there is emerging literature that attempts to address the role of radioiodine SPECT/CT in the evaluation of differentiated thyroid cancer (DTC). Most of these studies have studied adult patients and experience derived from children patients is still scarce. In this retrospective study, we attempted to investigate the utility of post-ablation 131I SPECT/CT on the impact of staging, and initial risk-stratification of children with DTC. Methods: Sixty-two children (45 female, 17 male; mean age, 14.5 ± 6.2y,range,6-21y) with DTC referred for initial postsurgical 131I ablation were retrospectively included. In addition to planar whole body scanning performed approximately 5 days after the therapeutic administration of 2,220-5,550 MBq (60-150 mCi) of 131I, SPECT/CT scanning of the neck and other suspected areas of abnormal radioactivity uptake noted on planar scans were acquired. Sites of uptake seen on planar and SPECT/CT images were categorized as thyroid remnants, cervical lymph nodes, and distant metastases. Each patient was initially staged using the 7th edition of the AJCC/UICC staging system (stage I, or II) and risk-stratified using the risk of recurrence stratification system proposed by the American Thyroid Association (low-, intermediate-, or high-risk), based on clinical and pathology information, and then re-classified, taking into account additional findings from post-ablation 131I SPECT/CT. Results: By addition of SPECT/CT, post-ablation 131I scans detected cervical lymph node metastases and distant metastases in 9 (14.5%) and 4 (6.5%) of 62 patients, respectively. Such additional findings noted from post-ablation 131I SPECT/CT helped to alter the staging and initial risk-stratification in 4 (6.5%) patient and 5 (8.1%) patients, respectively. Conclusion: Our study indicates that post-ablation 131I SPECT/CT scans have potential to identify regional and distant metastases, providing an important contribution to staging and initial risk-stratification in children with DTC. This work was supported by the National Natural Science Fund of China Grant No. 81401445, 81471693.

OP528

Red marrow and blood dosimetry in 131I treatment of metastatic differentiated thyroid carcinoma: comparison in patients with repeated treatments

E. Richetta, M. Pasquino, C. Cutaia, A. Giostra, R. Pellerito, M. Stasi; AO Ordine Mauriziano di Torino, Turin, ITALY

Aim. Radioiodine treatment of metastatic differentiated thyroid carcinoma is often limited by red marrow toxicity. In our institution 131I administered activity is individually planned: dosimetry to red marrow and blood is performed before therapy (PT) to determine the maximum tolerable activity (<2Gy) and after treatment (IT). In this study we compared the results of the dosimetries performed on patients with subsequent therapies to investigate the possibility of using the first dosimetry as a reference for the following treatments as well. Materials and Methods. For 32 metastatic patients PT and IT doses (d1) to red marrow and blood, evaluated according to AIFM protocol during a first 131I treatment, were compared with doses (d2) calculated in the later treatment (14 ± 7 months after). PT dosimetry was performed one week before radioiodine therapy by administering a 131I tracer-activity: 4 blood samples were acquired and AP-PA wholebody measurements were performed by using a NaI counter 2h, 24h, 48h and 96h after the administration. For IT dosimetry detectors placed on patients' beds providing wholebody AP counts (every 2h, from 8.00 a.m. to 22.00 p.m. during patient's hospitalization) and 4 blood samples were acquired with the same PT time scheduling. 64 couples of doses (30 PT and 34 IT) (Gy/GBq) were compared : percentage dose differences were calculated and a t-test for paired samples was applied.Results. Mean (±1Dev.St) percentage differences between d1 and d2 for the 30 PT paired data was -0.4%±14% [-19÷20] for red marrow and -5.2%±17% [-34÷25] for blood respectively. Good correlation coefficient r was found between d1 and d2, confirmed also by paired samples t-test (red marrow r=0.94, p=0.87 and blood r=0.83, p= 0.22). Similar results were found evaluating the 34 IT paired doses: red marrow mean difference 6%±11% [-14÷24], r = 0.95, p =0.15 and blood 4%±19% [-35÷39], r = 0.75, p =0.98. Conclusion. We performed a comparison between pre-treatment and in-therapy red marrow and blood doses evaluated in two subsequent treatments on 32 patients treated with 131I for metastatic differentiated thyroid carcinoma. The preliminary results show mean differences between the paired PT and IT doses not significantly different and percentage variations within the experimental error of the calculation method. The good correlation between the first calculate dose and the later result could confirm the possibility to use the first dosimetry as a reference for following treatment, avoid in such a way to repeat the very time expensive dosimetric procedure.

OP529

Pre-therapy Bone Marrow And Lesion Absorbed Dose Estimation Using Different Dosimetry Models In Metastatic Differentiated Thyroid Cancer

M. M. Abuqbeitah, H. Tanyildizi, I. Çavdar, M. Demir, N. Yeyin, B. Vatankulu, L. Kabasakal; Istanbul University, Istanbul, TURKEY

Aim: Dosimetry is an alternative strategy to the administration of fixed radioactive iodine in metastatic thyroid cancer therapy. Pretherapy dosimetry is increasingly recommended to calculate the maximum tolerable Activity for each patient in order to deliver absorbed dose not exceed 2 Gy for the red bone marrow and meanwhile optimization the response level of desired targeted lesions. Materials And Methods: 14 patients (10 female ,4 Male and Mean age 44±15.84 y ,TSH 65±43 μIU/ml,HTC 38.43±3.81 ng/ml) suffering from metastatic differentiated thyroid cancer were submitted to pretherapy maximum safe activity and lesion absorbed dose protocol to establish successive therapy using OLINDA/EXM Software and five different dosimetry Methods for comparison purposes. Dual head scintillation camera was utilized to measure whole body and lesions activities by drawing region of interest adjacent to whole body and lesion contours and performing attenuation correction Besides to Blood samples collection which were measured in Well-Gama Counter at several time points; 2.6.24.48.72.96.144hours after oral administration of Radioiodine tracer (2mCi).To verify normal background count rate, 1 minute acquisition was performed before each whole body scan and subtracted from the related scan's count. The necessary data were collected and modified according to the parameters of the dosimetry methods adopted by OLINDA/EXM, Wessels et *al*,Traino et *al*,Siegel et al,Shen et *al* ,and Keizer et *al* . Results: According to OLINDA/EXM software mean absorbed dose from tracer activity was 3.11±1.76mGy/mCi ,Wessels et *al* was 3.27±1.9mGy/mCi,Traino et *al* was 2.68±1.53 mGy/mCi,Kiezure et *al* was 2.2±1.16mGy/mCi,Siegal et *al* was 2.56±1.86 mGy/mCi , and Shen et *al* was 4.05±3.4 mGy/mCi. Mean absorbed dose to distal metastatic lesions was 6,31Gy/mCi. The deviation between the results of OLINDA/EXM software and the other dosimetry methods was variable 5.1%, -13.8%, 30%, -17%, and -29%. Conclusion: Absorbed dose and maximum safe activity determination by OLINDA/EXM software is non-invasive method and can be used in clinical routines easily. It seems that combination between red marrow absorbed dose and lesion absorbed dose in the dosimetry protocol is very advantageous to accomplish highly successive therapy and complete remission of the lesions.

111In-CP04 - A Novel CCK2/Gastrin Receptor-Localizing Radiolabelled Peptide Probe for management of Patients with Progressive/Metastatic Medullary Thyroid Carcinoma (MTC): Rationale, Study Design and the Initial Promising Results of a Multicentre First Phase Study.

A. Hubalewska-Dydejczyk[1], C. Decristoforo[2], P. Erba[3], R. Mikolajczak[4], H. Maecke[5], K. Zaletel[6], P. Kolenc-Peitl[6], T. Maina[7], P. Garnuszek[4], I. Virgollini[2], G. Geobel[2], M. Konijnenberg[8], M. Hendriks-deJong[8], L. Froberg[8], W.Lenda-Tracz1, C.Rangger2, A.Kunzmann5,A.Sowa-Staszczak1, M.Trofimiuk-Muldner1,M.Tomaszuk1; [1]Jagiellonian University Medical College, Krakow, POLAND, [2]Innsbruck Medical University, Innsbruck, AUSTRIA, [3]3Azienda Ospedaliero-Universitaria Pisana, Pisa, ITALY, [4]Radioisotope Centre POLATOM, National Centre for Nuclear Research, Otwock, POLAND, [5]University Hospital Freiburg, Freiburg, GERMANY, [6]University Medical Centre Ljubljana, Ljubljana, SLOVENIA, [7]INRASTES, NCSR "Demokritos", Athens, GREECE, [8]Erasmus University Medical Center, Rotterdam, NETHERLANDS

The prognosis for patients with MTC is relatively good, however nonoperable/recurrent disease develops in approximately 50% of patients. The diagnostic and therapeutic algorithms in MTC cases still need to be optimized, as imaging techniques will not show any disease until serum calcitonin approaches at least 150 pg/ml as well as patients with surgically unresectable disease are left with few therapeutic options with low efficacy. CCK2 receptor is overexpressed in MTC with high density and >90% incidence. Since 1990, a variety of CCK2 receptor related peptides were studied; the DOTA-(DGlu)6-Ala-Tyr-Gly-Trp-Met-Asp-Phe-NH2 (CP04) showed the most promising characteristics (high receptor affinity, high stability and low kidney retention) and was selected for further clinical evaluation.The aim of the project is to establish the multinational cooperation in the innovative field of targeted radionuclide therapy using a CCK-2/gastrin receptor-seeking ligand CP04 radiolabelled with Indium-111 as an imaging biomarker.Methods: The study consists of two stages: WP1-Radiopharmaceutical development and WP2-Clinical trial. The goal of WP1 was to establish a clinically useful formulation for the preparation of 111In-CP04 including radiolabelling and stability testing and the extended single dose toxicity study including haematology, blood chemistry and histopathology.Minimally 20 patients with progressive/metastatic nonoperable histologically proven MTC with positive 18F-FDG-PET-CT/CT/MRI or positive calcitonin doubling time will be enrolled in the clinical study.The objective is to establish the safety of i.v. administration of a therapeutic amount of 111In-CP04 and to assess the tracer's

biodistribution and dosimetry in MTC and normal tissues and to determine critical organs. The evaluation of the potential of CCK2 receptor scintigraphy to detect cancer lesions for diagnostic (10ug) and therapeutic peptide dose (50ug) and the decrease of kidney dose after co-administration of gelofusine (nephroprotective agent) are planned. Results: We demonstrated that radiolabelling of CP04 with 111In could be effectively translated into a clinically useful formulation based on a simple kit procedure. The planned peptide dose allows clinical administration based on preclinical toxicity data. Standard Operating procedures for radiolabelling and imaging methods as well as the Study Protocol and documents to obtain the ethics committee's approvals for all participating centres are being finalized. The study will recruit patients soon. Conclusion: The project may become the first step in establishing a more selective and efficient strategy for the diagnosis, early detection and therapy of recurrent/metastatic MTC patients leading to reduction of mortality as well as improvement in life quality. GRAN-T-MTC is the ERA-NET part (TRANSCAN, EC-FP7).

Measurement of sorafenib concentrations using PET imaging in patients with advanced solid malignancies

L. H. Mammatas, M. Yaqub, N. H. Hendrikse, O. S. Hoekstra, R. J. Honeywell, M. Meijerink, L. A. Schwarte, G. J. Peters, A. A. Lammertsma, H. M. W. Verheul, C. W. Menke-van der Houven van Oordt; VU University Medical Center, Amsterdam, NETHERLANDS

Aim: Sorafenib is an oral protein kinase inhibitor targeting VEGFR, PDGFR and Raf kinases. It is currently registered for the treatment of metastasized hepatocellular carcinoma, renal cell cancer and iodine-refractory differentiated thyroid cancer. However, sorafenib leads to a response in only a subgroup of patients, while all are exposed to potential toxicity. Positron emission tomography (PET) may provide a non-invasive technique to predict which patients will benefit from this treatment. We hypothesize that response to sorafenib is dependent on achieving pharmacological active drug levels in tumor tissue and that quantitative PET imaging using radiolabeled sorafenib can predict these tumor concentrations. Materials and methods: At our center the GMP-synthesis of [11C]sorafenib has been developed. In this single center, proof of concept study, adult patients with advanced, biopsy accessible malignancies are included for which standard palliative treatment with sorafenib is indicated. [11C]Sorafenib dynamic PET is performed before and after two weeks of standard treatment. Pharmacokinetic modeling is applied to describe the tissue distribution and tumor uptake of [11C]sorafenib. Moreover, the amount of tracer uptake in tumor and blood measured with PET imaging is compared to the actual pharmacological active drug concentrations in tumor biopsies and blood samples after 2 weeks of treatment measured with liquid chromatography-tandem mass spectrometry (LC-MS/MS). Results: Six patients have been included: 1 patient with metastasized hepatocellular carcinoma, 4 patients with metastasized renal cancer and 1 patient with metastasized iodine-refractory follicular thyroid cancer. There was high physiological uptake of [11C]sorafenib in liver, gallbladder and kidneys due to metabolism and excretion of sorafenib, respectively. [11C]sorafenib uptake in tumor lesions was observed in 2/6 patients. The correlation between PET uptake and tumor and blood concentrations of sorafenib after two weeks of treatment will be shown. Conclusion: This study is the first step necessary to assess the feasibility of [11C]sorafenib PET as a quantitative predictive tool in cancer treatment.

OP532

Early and late evaluation of solid tumours with 64Cu-ATSM PET/CT: *a computer-aided fractal analysis*

E. Lopci[1,2], F. Grizzi[1], I. Grasso[3], C. Russo[1], G. Cicoria[3], S. Cambioli[3], F. Lodi[3], A. Chiti[4], S. Mattioli[5], S. Fanti[5]; [1]Humanitas Clinical and Research Hospital, Milano, ITALY, [2]Alma Mater Studiorum University, Bologna, ITALY, [3]Ospedale S. Orsola-Malpighi, Bologna, ITALY, [4]Humanitas University, Milano, ITALY, [5]Alma Mater Studiorum Bologna University, Bologna, ITALY

Purpose: 64Cu-ATSM is a well-known PET radiopharmaceutical applied for tumour imaging of hypoxia. Due to the long half-life of the radionuclide, early and delayed images can be acquired. However, no real evidence exists on the consistency of these two point-in-time acquisitions. The current study aimed at analyzing early and delayed acquisition on 64Cu-ATSM PET/CT in the same cohort of patients by comparing the information obtained from parametrical and computer-aided fractal geometry based analysis of the DICOM images. Methods: Five patients with pathologically proven head and neck cancer (HNC) or locally advanced NSLCL were included in the study. Each participant received 105-500MBq of tracer according to body size and was scanned in a 3D-mode on a PET/CT tomograph 60 minutes (early) and 16 hours (late) after injection. PET images were reconstructed and visualized on a GE Advanced 4.6 workstation for the definition of semi-quantitative and quantitative parameters: SUV_{max}, $SUV_{ratio\text{-}to\text{-}muscle}$, SUV_{mean}, hypoxic volume (HV) and hypoxic burden

(HB=HV*SUV_{mean}). DICOM data retrieved from both scans were subsequently analyzed using an ad-hoc computer-aided software to determine the Mean Intensity Value (MIV), Standard Deviation (SD), Relative Dispersion (RD), 3D Histogram Fractal Dimension (3D HIST FR DIM) and 3D Fractal Dimension (3DFD). Differences in between the parameters were compared using the Student's t-test, by considering as statistically significant p-values <0.05. Results: All patients showed an increased uptake of 64Cu-ATSM in tumour lesions, with a $SUV_{ratio\text{-}to\text{-}muscle}$ at early imaging of median 4.42, median SUV_{max} of 5.3, median SUV_{mean} of 2.8. The HV and HB at early imaging resulted respectively of median 41.4cm^3 and 161.2cm^3. All these semi-quantitative and quantitative data obtained at 1 hour resulted consistent with the same data obtained on delayed imaging (p>0.05). However, a statistically significant difference was found when compared the SUV_{max} of the muscle (p=0.045). Fractal analysis demonstrated that all parameters considered at early and late acquisition showed no statistically significant differences (p>0.05). A borderline value was obtained for MIV (p=0.075). This latter finding is mainly attributable to the limited series of analyzed patients, and the difference reported on muscle SUV_{max} applied as reference tissue for tumour contouring. Conclusions: Our findings support the reliable and consistent use of 64Cu-ATSM PET/CT obtained at early and delayed acquisition for the assessment of tumour hypoxia. Some attention might be paid when utilizing the data for radiotherapy contouring, because reference tissue uptake such as muscle SUV_{max} can show some difference in between the two scans.

OP533

Molecular imaging of neuroendocrine tumors with Scandium-44: a novel tool for THERANOSTICS

A. Singh[1], R. P. Baum[1], I. Klette[1], N. P. van der Meulen[2], C. Mueller[3], A. Tuerler[2], R. Schibli[3]; [1]THERANOSTICS Center for Molecular Radiotherapy and Molecular Imaging, ENETS Center of Excellence, Zentralklinik Bad Berka, Bad Berka, GERMANY, [2]Laboratory for Radio- and Environmental Chemistry, Paul Scherrer Institute (PSI), Villigen, SWITZERLAND, [3]Center for Radiopharmaceutical Sciences, Paul Scherrer Institute (PSI), Villigen, SWITZERLAND

Aim: Scandium-44 (44Sc) is a novel β+-emitting radionuclide for PET imaging. Chemically, Sc3+ is similar to lanthanides and rare earth elements (90Y3+, 177Lu3+) in its ability to form DOTA complexes. Given the physical properties, it may complement the use of Galium-68 (68Ga; short-lived, t1/2 = 68 min) for molecular imaging of neuroendocrine tumors (NETs). We report molecular imaging data using 44Sc-DOTATOC PET/CT in three patients with metastatic NETs.Materials and Methods:44Sc (t1/2 = 3.97 h, Eβ+ 1475.4 keV, 94.34%) was cyclotron-produced at PSI Villigen (Switzerland), transported over 600 km by road to ZBB (Germany), and radiolabelled with the somatostatin analogue DOTATOC (DOTA0,Tyr3-octreotide) with a specificity of 10 MBq 44Sc/nmol DOTATOC, and a high radiolabelling efficacy (99% ± 1.6; pH range = 3-4.5). 44Sc-DOTATOC (78, 96, and 130 MBq) was administered to 3 male patients (age range 57-70 years) with GEP-NETs presenting for restaging. Whole-body PET/CT (Biograph mCT Flow 64) scans were performed at variable time intervals from 10 min to 24 h p.i. and target-to-non-target uptake ratios were determined. The total number of SSTR-positive lesions was counted and SUV were determined in normal organs and metastases. Imaging results were compared to US, MRI, and 68Ga-DOTATOC PET/CT.Results: Molecular imaging with PET/CT following injection of 44Sc-DOTATOC demonstrated high specific tracer uptake in liver and lymph node metastases, with best target-to-non-target ratios seen at 2 to 4 h p.i. Two patients were diagnosed with progressive disease (PD): five additional metastases were detected in one patient, and one new metastasis was revealed in the other patient, compared to the previous 68Ga-DOTATOC PET/CT study. One patient had a single new small metastasis, but overall regressive tumor burden. No adverse effects were observed in any of the patients. Conclusions:44Sc is a highly promising positron-emitting radioisotope for the molecular imaging of NETs. When produced centrally, several patient doses can be delivered to PET imaging centers at a distance of over 1,000 kilometers. In this series, 44Sc-DOTATOC was found safe for human use, exhibited high target-to-non-target ratios, and delayed imaging up to 24 h p.i was possible. 44Sc-DOTATOC provides high diagnostic sensitivity and excellent image quality for PET imaging, and also demonstrates significant prominence as a THERANOSTIC radionuclide, since pre-therapeutic imaging and dosimetry by 44Sc-DOTATOC may be followed by radiopeptide therapy using the β–emitting Scandium-47 (47Sc).

OP534

Determination of chemokine receptor CXCR4 by 68-Ga-Pentixafor PET in patients with adrenocortical carcinoma

C. Bluemel[1], S. Hahner[1], B. Heinze[1], A. Schirbel[1], M. Schottelius[2], C. Lapa[1], S. Kropf[3], K. Lückerath[1], B. Allolio[1], M. Fassnacht[1], H. Wester[2], A. K. Buck[1], K. Herrmann[1]; [1]Universitätsklinikum Würzburg, Würzburg, GERMANY, [2]Technische Universität München, München, GERMANY, [3]Scintomics GmbH, Fürstenfeldbruck, GERMANY.

Aim: The chemokine receptor CXCR4 and its chemokine ligand 12 are key factors for angioneogenesis, metastasis and tumour growth in several human cancers and also overexpressed in adrenocortical neoplasia. Recently, 68-Ga-Pentixafor PET for in vivo CXCR4- imaging was introduced. The aim of the present study was to evaluate 68-Ga-Pentixafor for in vivo determination of CXCR4-expression in patients with adrenocortical carcinoma (ACC) to select suitable patients for CXCR4-directed therapies in a theranostic concept. Methods: 22 consecutive patients with histopathological proven metastasized ACC were examined with 68-Ga-Pentixafor-PET/CT and 18-F-FDG-PET/CT. Results of both imaging methods were compared and patients were classified as suitable or unsuitable for CXCR4-directed therapy. Results: In all patients 18-F-FDG-PET/CT and 68-Ga-Pentixafor-PET/CT were rated positive (100%), 48% had a local recurrence, 52% peritoneal/mesenterial, 33% retroperitoneal tumour lesions, 29% had lymph node metastases and 86% haematogenous metastases. Visual comparison of both tracers resulted in comparable findings in 7 (32%) patients and 4 (18%) patients in complementary findings. In 9 patients (41%) 18-F-FDG-PET/CT identified more lesions with visually higher uptake compared to CXCR4-imaging, whereas in 2 patients (9%) 68-Ga-Pentixafor-PET/CT identified more metastatic lesions than 18-F-FDG. The corresponding mean SUVmax value for 18F-FDG was 12.28±8.35 (range, 2.17-47.04) and thus significantly higher than the SUVmax for 68Ga-Pentixafor (mean, 8.40±5.77; range, 1.75-34.18). Overall, 12 out of 22 patients (54%) were rated as suitable and 3 patients (14%) as potentially suitable CXCR4-directed therapy, e.g. 177-Lu/90-Y-labelled Pentixafor analogues. Conclusions: CXCR4 is overexpressed in a subgroup of ACC patients allowing for CXCR4-directed therapies in 67% of patients in the present cohort. 68-Ga-Pentixafor-PET/CT provides excellent imaging quality and allows for selection and therapy monitoring of patients suitable for CXCR4-directed therapy.

OP535

Diagnostic value of (68)Ga - PSMA PET/CT in biochemical recurrence of prostate carcinoma with low PSA levels

E. Demirci[1,2], J. Nematyazar[1], R. Akyel[1], B. Razavi[1], A. Aygun[1], M. Ocak[3], M. Halac[1], A. Araman[3], L. Kabasakal[1]; [1]Department of Nuclear Medicine, Cerrahpasa Medical Faculty, Istanbul University, Istanbul, TURKEY, [2]Department of Nuclear Medicine, Sisli Etfal Training and Research Hospital, Istanbul, TURKEY, [3]Department of Pharmaceutical Technology, Pharmacy Faculty, Istanbul University, istanbul, TURKEY.

Purpose: 68Ga-DKFZ-11 (68Ga-PSMA) has been suggested as a novel tracer for detecting of PCa relapses and metastases. However there is a limited number of publications about the timing of PSMA PET/CT scan. The aim of the study is to evaluate the diagnostic value of PSMA PET/BT in the diagnosis of recurrent prostate cancer with low PSA levels. Materials and Methods: We performed a retrospective analysis in patients who underwent PSMA PET/CT from November 2013 to December 2014 in our department. 53 out of 178 patients who had rising PSA levels (still lower than 5ng/ml), and did not have known metastasis were included in this study. Results: Patients had an average PSA of 1.41 ng/ml. A total of 31 patients (58%) showed at least one extraprostatic or prostatic lesions. Intense pathologic radiotracer uptake was observed in 15 patients (28%) at the site of primary tumor. Lymph node metastases were detected in 19 patients (36%) and bone metastases were detected in 8 patients (15%). A PET positivity rate of 31% (n=4), 54 % (n=13) and 88% (n=14) observed in patients with PSA level of <0.2, 0.2-2 and 2-5 ng/ml respectively. Those with PSA level PSA <0.2, 0.2-2and 2-5 ng/ml had 8% (n=1), 21% (n=5), 56% (n=9) local recurrence 15% (n=2), 42% (n=10), 44% (n=7) lymph node metastasis and %15 (n=2), 8% (n=2), 25% (n=4) bone metastasis. A positive correlation observed between positivity rate and gleason scores (%15 for Gleason 6, %55 for Gleason 7, 75% for Gleason 8 and 77% for Gleason 9). PSMA PET/CT positivity's confirmed with biopsy (n=3), follow-up (n=26) and conventional imaging studies at the time of the PET/CT (n=11) or during follow up (n=13). According to patient-based analysis of 44 cases %57(n=25) of patients had true positive, %23(n=10) of patients had true negative, %2(n=1) patient had false positive, %18(n=8) of patients had false negative findings which are leading to a sensitivity of 58.1% (95%CI:42.1-72.9%) specificity of 90% (%95CI:%48.6-98.5). Within the patients who had PSA levels from 0.2 to 5, the sensitivity was %79.3 (%95 CI: %60-91.9). Conclusion: PET/CT with 68Ga PSMA is a valuable tool for assessing recurrence of PCa with a high sensitivity (%79.3) within the patients who has PSA levels between 0.2-5 ng/ml. Additionally PSMA PET/CT can be used in patients with very low (<0.2 ng/ml) but increasing PSA levels, which in many cases may influence the further clinical management.

OP536

Preliminary comparison of PET/CT and PET/MRI hybrid systems using a Ga-68 labeled PSMA ligand for initial staging of prostate cancer

S. Lütje[1], B. Gomez[1], J. Cohnen[1], B. M. Schaarschmidt[2], R. Reichel[1], S. Rosenbaum-Krumme[1], A. Bockisch[1], T. D. Poeppel[1], A. Wetter[3]; [1]Clinic for Nuclear Medicine, University Hospital Essen, Essen, GERMANY, [2]Department of Diagnostic and Interventional Radiology, Medical Faculty, University Düsseldorf, Düsseldorf, GERMANY, [3]Department of Diagnostic and Interventional Radiology and Neuroradiology, University Hospital Essen, Essen, GERMANY.

Aim: Despite improvements in diagnostic and therapeutic approaches, prostate cancer remains one of the leading causes of cancer-related death in men in the Western world. ^{68}Ga-labeled HBED-CC-PSMA is a highly promising new tracer for imaging of PCa. The aim of this study was to evaluate the feasibility of PET/MRI with this tracer for detection and locoregional staging of PCa at initial diagnosis in comparison to PET/CT. Materials and methods: Ten high-risk patients (mean serum prostate-specific antigen 12.0 ± 9.2 ng/ml) among which seven were suspected with PCa in transrectal biopsy, underwent PET/CT 66 ± 17 min after injection of the ^{68}Ga-HBED-CC-PSMA ligand (mean 102 ± 18 MBq/patient) followed by PET/MRI at 153 ± 66 min postinjection. Data from the two investigations were analyzed separately and compared regarding tumor detection rate and radiotracer uptake in tumor lesions and muscle tissue. Uptake was quantified in terms of the maximal standardized uptake value (SUV_{max}) within a spheroidal volume of interest (VOI). SUVs of PET/CT and corresponding PET/MRI were compared to each other with paired t tests. Reference VOIs were drawn in the gluteal muscles on the right side. The native SUV_{max} of the lesions were normalized to the SUV_{max} in the reference region. Tumor lesions within the prostate visualized by both techniques were correlated to histopathological analyses. Results: With both techniques, 8 histologically proven tumor lesions were identified in 7 patients. In three patients with negative transrectal biopsy results, no tumor lesions were identified with PET/CT and PET/MRI. Even though SUVs in PET/CT were slightly higher (mean SUV_{max} 12.7 ± 9.1, n=8) compared to PET/MRI (mean SUV_{max} 9.6 ± 5.8, n=8), PET/MRI provided significantly higher tumor-to-muscle ratios compared to PET/CT (mean 15.8 ± 9.7 and 8.1 ± 5.1, respectively, p=0.0016). Conclusion: PET/MRI is as reliable as PET/CT for detection and locoregional staging of patients with PCa at initial diagnosis.

OP537

Evaluation of the role of F-18 FDG PET/CT in childhood rhabdomyosarcoma - preliminary results

R. K. Gupta, **Jr**., M. Tripathi, S. Bakshi, N. Damle, K. Kumar, R. Bhayana, C. Bal; All India Institute of Medical Sciences, New Delhi, INDIA.

INTRODUCTION: The management of rhabdomyosarcoma (RMS) depends on risk stratification at diagnosis & treatment response. The methods used for initial evaluation include histopathology (HP), magnetic resonance imaging (MRI), contrast enhanced computed tomography (CECT), chest X-ray (CXR), non-contrast computed tomography (NCCT) chest, Technetium-99m Methylenediphosphonate (Tc-99m MDP) bone scan (BS) and bone marrow biopsy. Fluorine-18 Fluorodeoxyglucose (FDG) PET/CT has emerged as a useful modality for staging malignancies. In this study we compared F-18 FDG PET/CT with conventional imaging (CI) modalities for the staging of RMS. MATERIALS AND METHOD: Twenty two children (16 males) with mean age 8.13 years (range 2 to 17 years) were prospectively enrolled in this study. All patients were biopsy proven RMS with positive desmin and myogenin. Each patient underwent CECT and/or MRI of the primary tumour site, CXR and/or NCCT chest and Tc-99m MDP BS. The disease was staged according to TNM Pretreatment Staging Classification[1]. Each patient also underwent F-18 FDG PET/CT within one week of the MRI/CECT and were restaged using the information obtained from PET/CT. Nodal status and metastases as obtained by conventional imaging and after PET/CT were compared. RESULTS: F-18 FDG PET/CT detected additional lesions in 59 %(13/22) patients. In comparison to CI, F-18 FDG PET/CT detected additional nodes in 13% (3/22)patients and ruled out nodal involvement in 4%(1/22) patients. Additional distant metastatic sites in lung and bone marrow were detected in 9 % (2/22) patients. N stage changed in 31 %(7/22) patients, M stage changed in 9% (2/22) patients. Overall TNM staging changed in 18 %(4/22) patients. CONCLUSION: This study suggests that F-18 FDG PET/CT has potential to increase initial staging accuracy, specifically detection of nodal involvement and distant metastatic spread. REFERENCE: 1. Lawrence W, Jr, Anderson JR, Gehan EA, et al. Pretreatment TNM staging of childhood rhabdomyosarcoma: A report of the Intergroup Rhabdomyosarcoma Study Group. Children's cancer study group. Impact of 18F-FDG PET/CT in the diagnosis and therapeutic response of histiocytosis

L. M. Vija[1], G. Bera[2], J. Haroche[2], F. Cohen[1], P. Chaumet-Riffaud[1], A. Prigent[1], P. Maksud[2]; [1]Paris Sud University, Le Kremlin-Bicetre, FRANCE, [2]Groupe Hospitalier La Pitié-Salpêtrière, Paris, FRANCE.

Objectives: Histiocytosis (with its heterogeneous group of Langerhans cell histiocytosis (LCH) and subtypes of non-LCH histiocytoses) is a rare inflammatory and systemic disorder of unknown origin, characterized by infiltration of histiocytes in the affected tissues. The objective of this study was to assess the impact of 18F-FDG PET/CT for the diagnosis and metabolic response to immunomodulatory treatments.Patients and methods:We retrospectively analyzed baseline and follow-up 18F FDG PET/CT exams as it follows: 406 exams in 85 patients with Erdheim-Chester disease (ECD), 15 exams in 5 patients with Rosai-Dorfman disease (RDD), 55 exams in 20 patients with LCH, 102 exams in 14 patients with combined forms of histiocytoses (LCH+ECD, LCH+RDD), as well as 6 exams in

3 patients with xanthogranulomatoses. As the gold standard (histological confirmation of all the metabolic localizations) cannot be achieved, 18F FDG PET/CT exams, were compared with organ/system based radiological (CT/MRI) findings (for example: thorax, abdomen and pelvis CT, brain MRI, cardiac MRI, bone MRI), specific for every patient. Metabolic responses to treatments (41 patients on interferon-α, 13 patients on vemurafenib and 7 patients on infliximab) were assessed by the ΔSUVmax (baseline-final)/baseline of the highest-uptake lesion. Concordances between 18F FDG PET/CT and CT/MRI were assessed by the kappa (κ) coefficient. Results: Besides a whole-body topographical characterization, 18F FDG PET/CT showed an overall sensitivity and specificity ranging from 33 to 100% and from 60 to 100% respectively, according to the organ or system explored. Highest rates of metabolic uptake detection by 18F FDG PET/CT in histiocytosis lesions of both ECD and mixed forms, compared with CT/MRI, concerned long bone lesions (80% vs 73% for ECD, 93% vs 86% for mixed forms), with an excellent concordance (κ=0,96 for ECD, κ=1 for mixed forms) between imagistic methods. 18F FDG PET/CT identified 17 metabolic responses (41%) on interferon-α (24-month median follow-up), one complete response and 8 (62%) partial responses on vemurafenib (12-month median-follow-up), as well as a partial response on infliximab (15-month median follow-up).Conclusions:The results of this large retrospective study suggest that whole-body 18F FDG PET/CT is informative at diagnosis for a better whole-body staging (rapid and more exhaustive identification of localisations) for each histiocytosis subtype and for the evaluation of the metabolic response to various immunomodulatory treatments.

Increased myocardial 18F-FDG uptake after doxorubicin-based chemotherapy in Hodgkin disease: an early predictor of cardiotoxicity?

M. Bauckneht[1], G. Ferrarazzo[1], F. Fiz[1], P. Ghione[2], F. Bongioanni[1], A. Nieri[1], M. Pennone[1], S. Morbelli[1], P. Spallarossa[2], C. Marini[3], G. Sambuceti[1]; [1]Nuclear Medicine, IRCCS AUO San Martino IST, Genova, ITALY, [2]Department of Internal Medicine, Chair of Cardiology, University of Genoa, Genova, ITALY, Genova, ITALY, [3]Institute of Bioimaging and Molecular Physiology, CNR, Milan, Genoa Section, Genova, ITALY, Genova, ITALY.

Aim. Doxorubicin-induced cardiotoxicity is related to many pathophysiological mechanisms, including oxidative stress and increased endothelin-1 serum levels. Previous in vitro studies documented that both these mechanism promote GLUT expression in cardiomyocite's sarcolemma. The aim of the present study was to verify whether this phenomenon can increase FDG uptake in the left ventricular myocardium of patients with Hodgkin disease (HD) treated with Doxorubicin-based chemotherapy scheme. Materials and Methods. We retrospectively analyzed FDG PET/CT scans of 24 patients with HD (mean age was 34±13) selected according to the following inclusion criteria: 1) absence of any history of cardiovascular disease; 2) full remission after two ABVD cycles; 3) availability of at least 4 consecutive PET/CT scan performed for staging (PET1), interim (PET2), post-therapy (PET3) and six month follow up (PET4) evaluation. Time points of PET/CT scan were thus at baseline and at 2, 6 and 12 months, respectively. Volumes of interest were manually drawn on the left ventricular myocardium and on skeletal muscle (paraspinal) to estimate mean (SUVmean) and maximum (SUVmax) standardized uptake values that were normalized for SUVmean determined by drawing a 1-cm oval region of interest in the aortic arch as an index of blood pool tracer concentration. Results. Normalized myocardial SUVmean was 2.08±1.29 at baseline and showed a progressive increase that became significant at PET3 (3.31±2.66, $p<0.05$) to remain stable in PET4 at 3.55±2.53 ($p<0.05$ vs PET1, p=ns vs PET3, respectively). Conversely, muscle SUVmean increased from PET1 (0.34±0.12) to PET3 (0.49±0.28, $p<0.05$); however, it returned to baseline values at PET4 (0.37±0.13) (p=ns vs PET1, $p<0.05$ vs PET3, respectively). Consequently, SUVmean increased from PET3 to PET4 in the myocardium, while it dropped in the skeletal muscle, as demonstrated comparing the PET4/PET3 ratio in these two tissues ($p<0.05$). The same results were obtained when compared myocardial and skeletal muscle normalized SUVmax. Conclusions. Present data demonstrate a divergent metabolic pattern between myocardium and skeletal muscle in young patients treated with a Doxorubicin-based chemotherapy for HD. Intriguingly, the

main difference between myocardial and skeletal muscle FDG uptake was detected at follow-up analysis when compared to staging and post-therapy evaluation. Although our protocol does not imply a sugar free diet in the days preceding the scans, the increased myocardial uptake trend and the divergent muscular metabolic performance could be at least partially explained by a Doxorubicin-induced myocardial GLUT overexpression.

OP541

Reverse mismatch in a patient cohort undergoing 18F-FDG/82Rb dual isotope PET for assessment of myocardial viability: Is it a significant clinical problem?

A. K. Hansen, M. Gejl, K. Bouchelouche, L. P. Tolbod, L. C. Gormsen; Aarhus University Hospital, Aarhus, DENMARK.

Background: Dual isotope myocardial positron emission tomography (PET) with perfusion (e.g. 82Rb PET) and metabolism tracers (18F-FDG viability PET) during hyperinsulinemia is currently widely used when myocardial viability is assessed. The technique is used to identify viable but underperfused myocardium (hibernating myocardium) in order to guide potential revascularization efforts. 18F-FDG viability PET relies on the assumption that all viable tissue takes up 18F-FDG when sufficiently stimulated by hyperinsulinemia. This may, however, not always be the case. It has thus been demonstrated that patients with type 2 diabetes (T2D), as well as patients with dilated cardiomyopathy, has severely depressed myocardial glucose uptake. In a clinical setting, this is highly unfortunate since 1) viable but non-FDG avid myocardium may appear hypometabolic , and 2) a large fraction of patients with heart failure suffer from either diabetes or dilated cardiomyopathy. Perfused but apparently hypometabolic myocardium is termed ”reverse mismatch”. Aim: To assess the fraction of patients with reverse mismatch in a mixed patient cohort undergoing 18F-FDG viability PET. Materials and methods: 92 heart failure patients (25 with diabetes) undergoing 18F-FDG viability were retrospectively reviewed. Resting perfusion was assessed by 82Rb PET (1110 MBq) followed by 18F-FDG PET scans (400 MBq) of the heart region. 18F-FDG uptake was stimulated by a total of 2 hours hyperinsulinemic-euglycemic (HE) clamp (1 mIE/kg/min). Percentage of hypoperfused and hypometabolic myocardium was calculated based on a 5-point score (17-segment model) divided by the maximum points obtainable. The difference between percentage hypoperfused and hypometabolic myocardium was calculated (DIF_PERF_MET) and interpreted as reverse mismatch if normal perfusion was observed with depressed metabolism. Coincident hypoperfusion and hypometabolism was considered scar whereas hypoperfusion with normal metabolism was considered hibernation. Results: In 31/92 patients hypometabolic myocardium significantly exceeded the percentage of hypoperfused myocardium (REVERSE PATIENTS) indicating reverse mismatch [DIF_PERF_MET (%): 30.7 +/- 13.5 (REVERSE PATIENTS) vs. 11.4 +/- 7.1 (SCAR AND HIBERNATION), $p<0.001$]. No correlation was observed between left ventricle volume and degree of reverse mismatch and no impact of diabetes status on reverse mismatch was observed. Hibernating myocardium was demonstrated in only one patient. Conclusion: In a mixed patient cohort undergoing HE-clamp and 18F-FDG viability PET, reverse mismatch was observed in 34 % of studies regardless of diabetes status. Since underestimated viability may severely impact the decision to revascularize patients, 18F-FDG PET viability studies should be interpreted cautiously and preferably in conjunction with results from other modalities (e.g. MRI).

OP542

Assessment of cardiac sympathetic nerve system in the rat heart using 11C-HED

Y. Maya[1,2], R. Werner[1,3], H. Wakabayashi[1], M. Nakajo[1], K. Fukushima[4], C. Lapa[1], K. Herrmann[1], T. Higuchi[1,3]; [1]Department of Nuclear Medicine, Universitätsklinikum Würzburg, Würzburg, GERMANY, [2]Research Centre, Nihon Medi-Physics Co., Ltd., Chiba, JAPAN, [3]Comprehensive Heart Failure Center, Würzburg, GERMANY, [4]Hyogo College of Medicine, Hyogo, JAPAN.

Objectives: The sympathetic nervous system of the heart plays a crucial role in various cardiac diseases including ischemic heart diseases and heart failure. High-resolution small-animal PET enables noninvasive and quantitative evaluation of the heart in rodent models of human diseases. In this study, we investigate the feasibility of assessing sympathetic nerve system activity with 11C-HED PET in rat hearts. Methods: To confirm the specificity of 11C-HED uptake in rat myocardium, 11C-HED with a wide range of specific activities was injected (48.7+/-9.7MBq, ranged 0.2-60.4μg/kg cold mass) into healthy rats (n = 14) via a tail vein. Dynamic 23-frame PET images were started just before the tracer administrations, and obtained over 30 min. Time activity curves were generated for myocardial tissue region of interest (ROI) at mid ventricular level and blood activity at left atrial cavity ROI. Cardiac 11C-HED retention index (%/min) was calculated as myocardial tissue activity at 20-30min divided by the integral of the blood activity curves. In rat model of transient ischemia (7 days after 20 min left coronary occlusion and reperfusion, n=2), 11C-HED PET and following 18F-FDG PET as a reference of myocardial viability was performed to evaluate the feasibility of assessing the local sympathetic nerve damage. Results: In healthy rat hearts, dynamic PET demonstrated stable, high contrast and homogeneous left ventricular myocardial uptake within 5 min after intravenous tracer injection. In different 11C-HED specific activities, the estimated retention index decreased as

loading cold mass increased. These data were well fitted by a dose-response model (r2=0.92), and the estimated IC50 value (95% confidence intervals) was 46.3 (34.6-62.0) μg/kg. In rat model of transient ischemia, PET imaging clearly visualized the 11C-HED uptake defect in the anterolateral wall, while 18F-FDG uptake was preserved throughout the ventricle at the 11C-HED defect area. Post mortem tissue analysis with HE staining and tyrosine hydroxylase nerve staining confirmed denervation but viable myocardium after transient coronary occlusion. Conclusions: Cold mass effect of cardiac 11C-HED uptake measured as retention index by PET showed specificity of the imaging signal in the rat heart. Furthermore, local impairment of 11C-HED uptake despite preserved 18F-FDG uptake indicates feasibility of regional assessment of sympathetic nerve damage in rat model of ischemia. A combination of serial 11C-HED PET imaging and rat model of cardiac disease would be one of the promising approaches to investigate further insight into the dynamic pathophysiology of sympathetic nervous system of the heart.

OP543

Value of attenuation correction in stress-only myocardial perfusion imaging using CZT-SPECT

J. D. van Dijk[1,2], M. Mouden[1], J. Ottervanger[1], J. A. van Dalen[1], S. Knollema[1], C. H. Slump[2], P. L. Jager[1]; [1]Isala hospital, Zwolle, NETHERLANDS, [2]MIRA: Institute for Biomedical Technology and Technical Medicine, University of Twente, Enschede, NETHERLANDS.

Purpose: Attenuation correction (AC) has been shown to enhance conventional stress-only SPECT myocardial perfusion imaging (MPI). However, it remains unknown whether the same holds true when using the newest generation cadmium zinc telluride (CZT)-based cameras. The aim of this study was to determine the value of attenuation correction on stress-only MPI using a CZT-SPECT camera. Methods: A retrospective analysis was performed including 107 consecutive stable, low to intermediate risk patients (age 60 ± 12 years, 43% male gender and BMI 28.1 ± 4.7 kg/m^2) who underwent clinically indicated MPI CZT-SPECT/CT (Discovery NM/CT 570c, GE healthcare). The stress scans were reconstructed with and without CT-based attenuation correction (AC). Three types of images were created for interpretation; only displaying reconstructed data without AC (NC), only with AC, and with both NC and AC (NC+AC). Next, two experienced physicians visually interpreted by consensus these 321 randomized images for diagnostic outcome (normal, equivocal, abnormal scan) without knowledge of patient's history or other clinical findings. We have recorded all relevant events, in example, late coronary revascularization (>60 days), non-fatal myocardial infarction and all-cause death, in a mean follow-up time of 47.7 ± 9.8 months. Results: The percentage of normally interpreted scans increased from 45% using the NC images to 72% and 67% using the AC and NC+AC images, respectively ($p<0.001$). The percentage of images interpreted as equivocal decreased when including attenuation correction from 43% to 20% and 24% for the AC and NC+AC images, respectively ($p<0.001$). In addition, comparable hazards ratios on the recorded events were observed between the normally interpreted NC and AC (1.16, p=0.86), or NC+AC (0.99, p=0.99). Conclusion: The use of AC decreases the need for rest imaging in CZT-based SPECT cameras. This has the potential to reduce the cumulative radiation dose and improves laboratory efficiency. Although we did not assess the direct diagnostic accuracy, patient outcome seems unaffected.

OP544

Characterization of a dedicated myocardial cardio-centric SPECT-TC System: a preliminary phantom study

E. Richetta, M. Pasquino, C. Cutaia, G. Brusasco, G. Santopolo, I. Trabucco, A. Guida, R. Pellerito, M. Stasi; AO Ordine Mauriziano di Torino, Turin, ITALY.

Aim: The increasing need of faster myocardial perfusion imaging and dose patient reduction are nowadays satisfied by a novel dedicated cardiac equipment. At our institution a SPECT-CT was recently installed: cardio-centric multifocal collimators combined with a dedicated reconstruction software increased sensitivity and allows shorter image acquisition times or lower patient dose. With the aim to define the best acquisition protocol, a cardiac phantom was scanned with different frames and times. Semi-quantitative analysis was performed and images were qualitatively evaluated by two experienced physicians. Materials and methods: A thoracic phantom (Biodex) with a cardiac insert, simulating a focal perfusion deficit in heart wall, was filled with 99mTc uniform activity (37 GBq, dose-rate 5-6 kcps); acquisition was performed with cardio-centric collimators (Siemens SMARTZoom, matrix 128x128, angle 59°-104°, zoom1), varying the number of views (#frame:32, 30, 28,26, 22, 20, 18,10) and acquisition time per view (20, 15, 10, 5 s). A CT thoracic scan was then executed to correct images for scatter and attenuation. Reconstruction was performed with dedicated myocardial algorithm (Siemens IQSPECT-Iterative Flash3D, 8iteration, 4subset). Images were qualitatively inspected by two experienced physicians. For a semiquantitative analysis, a 17-segments QPS-model was adopted to evaluate perfusion polar maps; perfusion index, deficit extent, TPD, stress score SS and S% were analyzed as function of number of views and time per view; results were correlated to acquisition time. Results: Qualitative analysis of images showed an improved uptake-to-background ratio for a 18 frame-20s acquisition; for acquisition time less

than 20 s a poor statistic was found. The 17-segment analysis showed no significant variations at varying the number of views from 32 to 18. Scores range showed minimal fluctuations when number of views was changed (extent [42-45], TPD [30-33], SS [23-25] S%[34-37]), confirming the qualitative analysis performed by physicians. Reducing time per views, the difference becomes higher (extent [42-50] , TPD [31-37], SS [23-28] S%[34-41]). Finally, reducing frames from 32 to 18, the acquisition time decreases up to 60% with a substantially equal image quality. Conclusions: The best acquisition protocol was defined to optimize the procedure (18 frame-20s), according to qualitative and quantitative analysis. This operating mode, feasible only with this dedicated myocardial cardio-centric SPECT-TC System, allows to reduce acquisition time (or dose to patients) up to 40%, compared to standard protocols with an improved image quality.

OP545

Gated Myocardial Imaging: The impact of FBP and OSEM Image Reconstruction and Filtering on values of Left Ventricle function calculated with a commercial program - QGS*

D. S. Rosário; Karolinska Institutet, Stockholm, SWEDEN.

Aim: MPI tomographic (GSPECT) images are acquired synchronized with a patient's ECG for both stress and rest phases. These are reconstructed, processed and compared to detect changes in myocardial perfusion and left ventricular (LV) function. MPI image quality is strongly affected by the filtering process executed in GSPECT reconstruction. The optimal choice and selection of filter parameters is still considered a problem in the reconstruction process. The aim of this study was to evaluate how the change of filter parameters in Filtered Back Projection (FBP) and Ordered Subset Expectation Maximization (OSEM) reconstruction techniques affect the LV functional values calculated by QGS, a commercial program and the accuracy of the values as compared to ultrasound measurements. Methods: Thirty patients were included in study. GSPECT images were acquired in the stress and rest phases. A two days protocol was used and the radiopharmaceutical for both phases was 99mTc-sestamibi. The LV functional values (ejection fraction (LVEF), end diastolic volume (EDV) and end systolic volume (ESV)) were calculated with the QGS program for 8 different reconstruction procedures: FBP reconstructions and a Butterworth filter, using the same order, equal to 5, but changing the cut-off frequencies, which were: 0.20, 0.30, 0.40 and 0.50. For OSEM, all reconstructions were made with 4 iterations with 8 subsets and a Gaussian filter with different FWHM (mm), which were: 4, 8, 14 and 20. Reference LVEF values were calculated from ultrasound studies using Simpson's method. Results: There was a good correlation between functional values for most of the filter functions between phases and for LVEF against ultrasound, irrespective of reconstruction method. For FBP with a Butterworth filter with cut-off frequency 0.20 and OSEM with a Gaussian filter with FWHM 20, however, all correlations were poor. Discussion and Conclusions: LV functional values were shown to fairly independent of reconstruction method and filter function unless a very low pass filter was used. The good correlation between stress and rest phases showed that values were reproducible provided the perfusion distribution and LVEF were similar for both phases. There was also a good correlation between LVEF values measured with GSPECT and ultrasound. The best correlation was obtained with filters that resulted in noisy images. Since there were individual variations in LV functional values that could have affected a diagnosis, it may be better to choose reconstruction parameters that produce images that can be qualitatively assessed to ensure that the calculated are reasonably correct.

OP546

Feasibility of an eighth-time gated myocardial perfusion SPECT functional imaging using IQ-SPECT system.

F. Caobelli[1], J. T. Thackeray[1], A. Soffientini[2], F. M. Bengel[1], C. Pizzocaro[2], U. P. Guerra[2]; [1]Hannover Medical School, Hannover, GERMANY, [2]Fondazione Poliambulanza, Brescia, ITALY.

Background: IQ-SPECT, an add-on to general purpose cameras based on multifocal collimation, can reduce scan acquisition time to one fourth of standard procedures (12s/view) in myocardial perfusion imaging (MPI). In a phantom study, a reduction to one eighth of standard acquisition time (6s/view) was demonstrated as feasible. It remains unclear whether such a reduction could be extended to clinical practice. Methods: Fifty patients with suspected or diagnosed CAD underwent a two-day stress/rest 99mTc-sestamibi MPI protocol. Two consecutive SPECT acquisitions (6 and 12s/view) were performed. Electrocardiogram-gated images were reconstructed with and without attenuation correction (AC).Polar maps were generated and visually scored by 2 blinded observers for image quality and perfusion in 17 segments. Global and regional summed stress (SSS), summed rest (SRS) and summed difference scores (SDS) were determined. Left ventricular volumes and ejection fraction were calculated based on automated contour detection. Results: Image quality was scored higher for 12s/view scans, both with and without AC. Summed scores were statistically comparable between 6 and 12s/view acquisitions, either globally or in individual coronary territories (e.g. in AC images 6s vs 12s/view: SSS 6.6±8.3 vs 6.2±8.2, p=0.10; SRS 3.9±5.6 vs.3.5±5.3, p=0.19; SDS 2.8±5.7 vs. 2.6±5.7, p=0.59). Both acquisitions allowed an MPI-based diagnosis

of CAD in 25/50 patients (AC). End diastolic and end-systolic calculated volumes were modestly higher from 6s/view acquisitions compared to 12s/view (EDV +4.8 ml at rest and + 3.7 ml after stress,p=0.003; ESV +4.1 ml at rest and +2.6 ml after stress,p=0.01), whereas ejection fraction did not differ (-1.2% at rest, p=0.20 and -0.9% after stress, p=0.27). Conclusion: Image quality and LV functional parameters acquired at one eighth time were statistically comparable to the previously validated one fourth time protocol using IQ-SPECT. Shorter acquisition times without loss of diagnostic accuracy provides for improved patient comfort and streamlined departmental efficiency.

OP547

Impact of Data-Driven Respiratory-Motion Correction on the Extent/Severity of Myocardial Perfusion Defects of MPI SPECT Acquired with Discovery NM 530c: REGAT Software

D. Daou[1,2], R. Sabbah[3], H. Bouladhour[3], C. Coaguila[4]; [1]Cochin Hospital, APHP, Paris, FRANCE, [2]EA 7334 REMES, Université Paris-Diderot, Sorbonne Paris-Cité, Paris, FRANCE, [3]CHU Jean Minjoz, Besançon, FRANCE, [4]Centre Hospitalier de Bigorre, Tarbes, FRANCE.

Aim: We previously developed a data-driven respiratory-motion (RM) correction method for conventional SPECT gamma-cameras (REGAT) and adapted it to CZT multi-pinhole detector gamma camera (Discovery NM 530c). We recently reported that REGAT is clinically feasible, easily applicable and presents interesting impact on image characteristics when applied to myocardial perfusion SPECT imaging (MPI) realized with Discovery NM 530c. In this preliminary evaluation, we aimed to study whether REGAT applied to MPI (Discovery NM 530c) impacts the extent/severity of MPI defects (MPD). Materials and Methods: Were included 25 patients addressed for stress/rest MPI. All patients had prone stress MPI (2 MBq/Kg 99mTc-Tetrofosmin) than prone rest MPI 3-hours later (n=24/25 pts, 6 MBq/Kg). All acquisitions were made on Discovery NM 530c. Each list mode acquisition was processed to generate a dynamic SPECT acquisition study of 500 msec duration. Each dynamic SPECT study was processed to generate its corresponding data-driven RM curve. This curve was used to generate a mean RM GSPECT study which was reconstructed on Xeleris workstation. The corresponding reconstructed RM gated volumes were summed either without realignment (nonR-SPECT) or after rigid realignment (R-SPECT). These nonR-SPECT and R-SPECT studies (49 = 25 stress+24 rest) were classified by an experienced observer as presenting an impact (G1) or no impact (G2) on severity/extent MPD: an impact was considered present if ≥ 1 LV segment presented a modification ≥ 1 score (LV: 17 segments; 5 point scoring). Were noted the maximal RM in the 3 axis of reoriented LV: anterior/inferior (A-I), septal/lateral (S-L) and basal-apical (B-A) axis. Was also calculated variation of LV myocardial counts (LV-Max, %) between both R-SPECT and nonR-SPECT LV-Max. Results: A_I movement was the dominant movement (n=49): A-I, S-L and B-A axis were 9.7±4.6 mm, 1.8±1.1 mm, 3±2.3 mm. Variation in LV-Max (n=49) was 2.75±3.61 %. G1 consisted of 7/49 studies (14%). In G1 vs G2, variations in LV-Max were 3.7±7.9 % vs 2.6±2.4% (NS), and A_I movement were 15.7±3.5 mm vs 8.7 ±4 mm respectively (P<0.01). The cumulative % studies presenting with a positive impact on MPD (Cum) was correlated to the A_I movement: Cum (%) = 0.0043*A_I2 - 0.0325*A_I + 0.2099 (r2=0.9725, P<0.0001). In 13/49 studies (27%) with A_I >12 mm, 6/13 (46%) presented an impact on MPD. Conclusion: Data-driven respiratory-motion correction of MPI with Discovery NM 530c appears to impact MPD in a substantial number of studies. Its incidence is related to the magnitude of RM.

The Influence of ^{68}Ga-DOTATATE PET/CT Imaging in the Management Decision of Patients with Neuroendocrine Tumors

E. Skoura[1], O. M. AlMukhalid[1], E. Panagiotidis[1], M. Al Harbi[1], I. Kayani[1], S. Michopoulou[1], R. Syed[1], P. J. Ell[1], M. E. Caplin[2], J. Bomanji[1]; [1]UCLH, London, UNITED KINGDOM, [2]Royal Free Hospital, London, UNITED KINGDOM.

Aim: ^{68}Ga-DOTATATE PET/CT scan is a widely accepted method for imaging of neuroendocrine tumors (NET). This study evaluates the role of ^{68}Ga-DOTATATE PET/CT scan to influence management decisions in patients with NETs and evaluates any possible correlation between ^{68}Ga-DOTATATE PET/CT findings and patients' survival data. Materials and methods: Clinical outcome, survival, and change in management after ^{68}Ga-DOTATATE PET/CT were evaluated. Data from NET multidisciplinary team (MDT) minutes, patient discharge summaries and correspondence was reviewed to evaluate the influence of ^{68}Ga-DOTATATE PET/CT scan on patients' treatment plan. Results: During eight year time, more than 1000 ^{68}Ga-DOTATATE PET/CT scans were performed in patients with confirmed or suspected NETs. The findings of ^{68}Ga-DOTATATE PET/CT scans changed the patients' treatment plan in about 41% of the cases. The change in therapeutic management consisted mainly of resection of a previously unknown primary tumor, initiation of chemotherapy or peptide receptor radionuclide treatment (PRRT) due to

recurrence, change to chemotherapy instead of surgery or change to PRRT instead of chemotherapy. The most frequent management change was observed in patients with lung NET and medullary thyroid carcinoma while in patients with unknown site of primary NET, the change in treatment plan was lower. Furthermore, Kaplan Meier analysis has shown that the survival rates at 3 and 5 years after the ^{68}Ga-DOTATATE PET/CT scan was significantly better in patients with negative scans compared to those with positive scans ($p<0.01$). Conclusion: This large study demonstrates that ^{68}Ga-DOTATATE PET/CT scan can change the treatment plan in a significant percentage of patients with NET. Also, it is shown that a negative ^{68}Ga-DOTATATE PET/CT scan is associated with significantly better survival

OP549

Do we need full-dose contrast-enhanced CT for extra-hepatic staging using Gallium-68-DOTATATE-PET/CT in patients with neuroendocrine tumors (NET)?

A. Heinzel[1], D. Albanus[1], F. Verburg[1], F. Behrendt[1], F. Mottaghy[1,2], Z. Erdem[3], O. Erdem[3], J. Apitzsch[4]; [1]UK Aachen, Aachen, GERMANY, [2]Maastricht University Medical Center, Masstricht, NETHERLANDS, [3]Bülent Ecevit University, Karaelmas, TURKEY, [4]UK Gießen and Marburg, Marburg, GERMANY.

Aims: Previous studies have demonstrated that PET/CT with 68Ga-labeled somatostatin analogues is helpful in the assessment of the presence of metastatic disease in in patients with neuroendocrine tumors (NET) especially with regard to extra-hepatic metastases such as bone and lymph node metastases. It has to be noted that the PET in combination with full-dose contrast-enhanced CT (ceCT) exposes the patients to a high dose of radiation (up to 25Smv) whereas the non-contrast-enhanced low-dose CT (ldCT) might reduce the radiation to about 10mSv and at the same time avoid potential side effects of the contrast agent. Thus, we aimed to determine whether ceCT can be omitted in the assessment of extra-hepatic metastases in patients with NET. Methods/Materials: We retrospectively compared the performance of PET/ldCT versus PET/ceCT in 54 patients (26 male, 28 female) who underwent a Gallium-68-DOTATATE-PET/CT in our clinic. Patients were selected according to following criteria: available ldCT and ceCT; histologically confirmed NET; available follow-up of at least 6 months (median 12.6 months; range 6.1-23.2). PET/ldCT and PET/ceCT images were analyzed separately. The review process focused on metastases to bones and lymph nodes. Afterwards, the PET/ldCT and PET/ceCT results were compared to the reference standard consisting of clinical follow-up data to evaluate the diagnostic performance. Results: In PET/ceCT 139 true positive bone-lesions were detected compared to 140 in PET/ldCT, 106 true positive lymph node metastases (PET/ceCT) vs. 90 (PET/ldCT). On a per patient basis ld and ce PET-CT achieved similar sensitivity (both 100%) however, specificity was lower for PET/ldCT (89% vs. 77%). For lymph nodes PET/ceCT showed superior sensitivity and specificity (sensitivity 92% vs. 80% and specificity 83% vs. 65%). The positive predictive value (PPV) and negative predictive value (NPV) of PET/ceCT were 81% and 100% for bone metastases as well as 82% vs. and 92% for lymph node metastases. In contrast, PET/ldCT showed 91% PPV and 100% NPV for bone metastases as well as 78% PPV and 68% NPV for lymph node metastases. Conclusions: We demonstrate that ceCT should not be omitted for extra-hepatic staging using Gallium-68-DOTATATE-PET/CT in patients with neuroendocrine tumors. With regard to the detection of lymph node metastases ceCT is helpful to minimize false positive lesions. However, if only bone metastases are considered PET/ceCT and PET/ldCT show similar diagnostic performance.

OP550

The clinical role of Ga-68 DOTATE PET-CT in patients with neuroendocrine tumors

M. Tuncel[1], S. Kılıçkap[2], E. Akdemir[1]; [1]Hacettepe University, Department of Nuclear Medicine, ANKARA, TURKEY, [2]Hacettepe University, Department of Medical Oncology, ANKARA, TURKEY.

AİM: The introduction of Ga-68DOTATE PET-CT for the evaluation of neuroendocrine tumors(NETs) has significantly improved the diagnostic work-up. However impact on patient management is yet to be determined. We aimed to evaluate the clinical impact of the Ga-68DOTATE PET-CT in our patients suffering from NETs. Material & METHODS: The clinical and imaging data of 61 consecutive patients (F/M:35/26; agemedian:56±14years,range:22-82) with diagnosis of NET (9 carcinoids,2 pheochromocytomas,3 paragangliomas,4 medullary thyroid carcinomas,2 poorly and 41 well-differentiated gastroenteropancreaticNETs) were studied. All patients underwent Ga-68DOTATE PET-CT imaging for staging(n=9), restaging-suspected reccurence(n=48) and therapy response evaluation(n=4). Both PET-CT and conventional imaging (CI) were than interpreted together with medical oncologist to determine the clinical impact of the Ga-68DOTATE PET-CT. As a standard of reference clinical and imaging follow-up data were used (median:14 mo; range:9-48 mo). RESULTS: In 11 patients, PET-CT detected additional lesion sites (15 lesion sites in 10 patients), that are not detected by CI(3 endobronchial,5 lymph node,2 intestinal,2 pancreas and 3 bone, medianSUVmax:7[3-16], lesion size:10mm[5-20]). SUVmax values of lesions were higher in patients in whom

more lesions were seen by PET-CT (SUVmaxmedian:5.5 vs 20p<0.0001). Thirteen (21%) patients were interpreted as no evidence of disease by both PET-CT and CI. In 18/61(30%)patients, although detected malign lesions, Ga-68DOTATE PET-CT had no clinical impact over CI. PET-CT changed clinical management in 30/61(49%) patients;peptide receptor radionuclide therapy(PRRT) was considered as a systemic therapy option other than chemotherapy in 12/30(40%) patients due to high (tumor/liver SUVmax>2.2) radiotracer uptake, PRRT was prevented in 8/30(27%) patients due to low radiotracer uptake. PRRT was decided in 3(10%) patients instead of surgery/local ablative therapy due to systemic disease detected by PET-CT, 4/30(13%) patients underwent surgery for recurrence detected by PET, instead of follow-up with somatostatin analogue, systemic chemotherapy was decided instead of local therapy in 2/30(7%) patients, and radiofrequency ablation was decided for equivocal liver lesion on CI due to positive PET findings in 1/30(3%) patient. Among these 61 patients 17 patients also had FDG PET-CT in 2 months of Ga-68DOTATE PET. There was a negative correlation between FDG PET-CT and Ga-68DOTATE PET-CT (Spearman correlation coefficient-0,372 p:0,156). CONCLUSION: Ga-68DOTATE PET-CT has a major clinical impact in 49% of pts with NETs. It has detected more lesions than CI especially in patients with high radiotracer uptake and negatively correlated with FDG-PET. Our results indicate Ga-68DOTATE PET-CT as a mandatory procedure to guide patient management

OP551

Validation of parametric net influx rate images of ^{68}Ga-DOTATOC and ^{68}Ga-DOTATATE

E. Ilan, M. Sandström, I. Velikyan, A. Sundin, M. Lubberink; Section of Nuclear Medicine and PET, Department of Surgical Sciences, Uppsala University, Uppsala, SWEDEN.

Objectives: ^{68}Ga-DOTATOC/^{68}Ga-DOTATATE are radiolabelled somatostatin analogues used for diagnosis of somatostatin receptor(SSTR)-expressing neuroendocrine tumours.In addition, their use in treatment follow-up has been proposed. However, for these tracers SUV does not correlate linearly with the net influx rate(Ki), assumed to reflect SSTR density. Changes in Ki may better reflect treatment effects than changes in SUV, and it would be desirable to be able to compute parametric images showing Ki at the voxel level. The aim of this study was to evaluate parametric methods for computation of Ki images, and to compare image contrast in terms of tumour to liver ratio for parametric Ki images and SUV images. Materials and methods: Ten patients with metastatic neuroendocrine tumors underwent a 45-min dynamic scan followed by a whole-body (WB) PET/CT scans at 1 h post injection of ^{68}Ga-DOTATOC and ^{68}Ga-DOTATATE on consecutive days.The Ki was determined by nonlinear regression of an irreversible two-tissue-model as well as the Patlak method, using a descending aorta input curve. Parametric Ki images were made using a basic function method (BFM) implementation of the two tissue irreversible compartment model and Patlak method, and mean tumor Ki values were determined for 50% isocontour VOIs. Liver VOIs were drawn over WB and Ki images and tumour to liver ratios were calculated. The relation between the ROI-based and parametric Ki values were evaluated by using linear regression. Results: The correlation (R^2) between the ROI based (irreversible two-tissue-model) and parametric based (BFM) Ki images were 0.83 and 0.97 for ^{68}Ga-DOTATOC and ^{68}Ga DOTATATE, respectively with a slope of 1.0 in the both fits. The correlation (R^2) between the ROI based (Patlak) and parametric based (Patlak) Ki images were 0.95 and 0.76 for ^{68}Ga-DOTATOC and ^{68}Ga DOTATATE respectively with a slope of 1.1 in the both fits. The contrast between tumour and liver is 1.7 and 1.8 times higher in the parametric Ki images based on BFM than in the 1h WB images for ^{68}Ga-DOTATOC and ^{68}Ga-DOTATATE respectively. For parametric Ki images based on Patlak method the contrast is 2.4 and 2.7 times higher for ^{68}Ga-DOTATOC and ^{68}Ga-DOTATATE respectively. Conclusion: A good correlation and agreement between the parametric and ROI-based Ki values was found, showing that parametric K_i images are quantitatively accurate. In addition, tumour to liver contrast was higher in the parametric Ki images than in the 1h WB images both for ^{68}Ga-DOTATOC and ^{68}Ga DOTATATE.

OP552

68Ga-DOTA-NOC PET/CT SUVmax in patients with pancreatic NET: is it prognostic?

V. Ambrosini[1], G. Polverari[1], D. Campana[2], G. Cacciari[2], C. Peterle[1], S. Diodato[1], C. Nanni[1], G. Montini[1], P. Tomassetti[2], S. Fanti[1]; [1]Nuclear Medicine, University of Bologna, S.Orsola-Malpighi Hospital, Bologna, ITALY, [2]Internal Medicine, University of Bologna, S.Orsola-Malpighi Hospital, Bologna, ITALY.

Aim: to investigate the role of SUVmax measured on 68Ga-DOTA-NOC PET/CT as a potential prognostic factor in patients (pts) with pancreatic NET (pNET) . Materials and methods: Among the pts who underwent 68Ga-DOTANOC PET/CT from September 2006 to October 2014, those with pathologic confirmation of well differentiated pNET (WHO 2010: G1 or G2), documented disease at both 68Ga-DOTA-NOC PET/CT and CT (performed within a month) and a minimum clinical-radiological follow-up of 6 months (mo) were included in the study. Radiological follow-up consisted of a CT scan every 3 mo during the first year and every 6 mo afterwards. Pts with MEN syndrome were excluded. To evaluate the potential role

of SUVmax on prognosis, we divided the pts on the basis of the disease status at 24 months follow-up: pts with progressive disease (PD) were compared to those with stable disease (SD) or partial response (PR). Results: Overall 43 pNET pts were included (male:female=22:21; mean age=61.0±11.7 [35-81] years). In 35/43 (81,4%) the tumour was non-functioning while 8/43 (16, 3%) presented a clinical syndrome. Ki67 was ≤5% in 22/43 pts and >5% in 21/43 pts. TNM stage was III in 7 pts (16,3%) and IV in 36 (83,7%). Overall 18 pts (41,8%) had SD/PR while in 20 (46,5%) the disease progressed. SUVmax values were significantly higher (p=0.022) in pts presenting SD/PR (median 49.8, IQR25-75%:44.9-78.8) as compared to those with PD (median 33.4, IQR25-75%:26.1-52.4). At univariate analysis, risk factors for disease progression during follow-up included ki67>5% (p=0.009), SUVmax <37.8 (p=0.003) and medical therapy alone (as compared to medical therapy associated with PRRT, p=0.018). Stage IV (p=0.026), ki67>5% (p=0.009), SUVmax<37.8 (p=0.043) and medical therapy alone (p=0.015) were also confirmed at multivariate analysis. Conclusions: Our data provide evidence of the role of SUVmax as an accurate non-invasive parameter of disease prognosis in pts with pNET. Although not an objective of our study, our data also confirm the role of PRRT in pts clinical management.

OP553

Head-to-head comparison of 68Ga-DOTA-NOC and 18F-FDG PET/CT in neuroendocrine tumours: correlation between maximum standard uptake values and Ki67 proliferation index

R. Ferreira[1], R. Silva[1], A. Moreira[1], P. Lapa[1], P. Lapa[1], G. Costa[1], G. Costa[1], J. Lima[2]; [1]Serviço de Medicina Nuclear do Centro Hospitalar e Universitário de Coimbra, Coimbra, PORTUGAL, [2]Instituto de Ciências Nucleares Aplicadas à Saúde, Coimbra, PORTUGAL.

Introduction: Neuroendocrine tumours (NETs) have a heterogeneous biological behaviour that poses many clinical challenges and may compromise accurate diagnostic management, with consequences in treatment decision and prognosis evaluation. It is usually accepted that 68Ga-DOTA-NOC PET/CT is more useful in tumours with Ki67≤20% and that 18F-FDG PET/CT is more accurate when Ki67>20%. Aim: To compare 68Ga-DOTA-NOC and 18F-FDG PET/CT maximum standard uptake values (SUVmax) and correlate them with Ki67-indexes, in both primary and metastatic target (most relevant) lesions, in NETs. Materials and methods: We retrospectively reviewed patients with NETs, subjected to PET/CT with both 68Ga-DOTA-NOC and 18F-FDG, between March/2013 and March/2015. Both studies were performed 2.3±2.0 months apart. The patient's management and disease condition did not change during that period. Sixteen patients [13 male, 3 female; mean-age 68.2±12.4years(39-92); 11 gastroenteropancreactic-NETs and 5 lung-NETs] were selected. In 12 patients (75%), both exams were performed during staging and in 4 cases (25%) during follow-up. Primary tumour was present in all staging cases and was absent in all follow-up studies. Metastases were detected in 9 patients (5 in staging; 4 in the follow-up). SUVmax was recorded in 33 lesions (12 primary and 21 target metastases). Primary lesions were divided into two groups regarding Ki67: Group-1 (Ki67≤20%;n=5) and Group-2 (Ki67>20%;n=7). The 21 target metastases were also divided into two groups regarding Ki67 of the primary tumour: Group-A (Ki67≤20%;n=9) and Group-B (Ki67>20%;n=12). Results: The mean±SD SUVmax for 68Ga-DOTA-NOC and 18F-FDG was, respectively, 14.5±10.2 and 4.8±5.5 in Group-1, and 4.6±1.6 and 25.0±8.0 in Group-2. When comparing SUVmax between the two groups, we found a statistically significant difference with 68Ga-DOTA-NOC (p<0.05), but not with 18F-FDG SUVmax (p=0.17). In both groups, no significant tendency for higher SUVmax values of either of the radiopharmaceutical was observed (p=0.23;p=0.13). For target metastatic lesions, we conducted a similar analysis and found a statistically significant difference for 68Ga-DOTA-NOC SUVmax between Groups A and B (p<0.05) but not with 18F-FDG SUVmax(p=0.06). In Group-1 patients with metastases (5 cases), no statistically significant differences were observed in SUVmax values (for both 68Ga-DOTA-NOC and 18F-FDG), between primary and metastatic target lesions. Conclusion: Our data are consistent with the well-documented functional heterogeneity of NETs. They suggest that there is no direct association between somatostatin-receptor expression and metabolic degree of activity in these tumours. Therefore, we may conclude that these patients might benefit, despite de Ki67 proliferation index, from a complementary evaluation of both 68Ga-DOTA-NOC and 18F-FDG PET/CT.

OP554

68Ga-DOTANOC PET/CT imaging in localizing the primary site in patients presenting with metastatic neuroendocrine tumors and its impact on clinical decision making: Experience from a tertiary care centre in India

A. Pruthi, P. Pankaj, R. Verma, A. Jain, E. S. Belho, H. Mahajan; Sir Ganga Ram Hospital and Research Centre, New Delhi, INDIA.

Neuroendocrine tumours (NETs) are rare, heterogeneous group of tumours originating from small, occult primary sites and are characterized by over-expression of somatostatin receptors (SSTRs).Purpose: To retrospectively evaluate the efficacy of 68Ga-DOTANOC PET/CT imaging

in detecting the primary site in patients with metastatic neuroendocrine tumours of unknown origin and its impact on clinical decision making in such patients. Methods: Between December 2011 and September 2014, a total of 263 patients underwent 68Ga-DOTANOC PET/CT study in our department for various indications. Out of them, 68 patients (45 males, 23 females, mean age 54.9 +/- 10.7 years, range 31-78 years) with histopathologically proven metastatic neuroendocrine tumours and unknown primary site on conventional imaging underwent 68Ga-DOTANOC PET/CT as part of their pre-treatment staging work-up. Histopathology (wherever available) and/or follow-up imaging with biochemical markers were taken as reference standard. Quantitative estimation of SSTR expression in the form of maximal standardized uptake value (SUVmax) of detected primary and metastatic sites was calculated. Follow-up data of individual patients was collected through careful survey of electronic medical records and telephonic interviews. Results: Maximum patients presented to our department with hepatic metastasis (50 out of 68 patients) and grade I neuroendocrine tumours (>50%). 68Ga-DOTANOC PET/CT scan identified primary sites in 40 out of these 68 patients i.e. in approximately 59% patients. Identified primary sites were: Small intestine (19), Rectum (8), Pancreas (7), Stomach (4), Lung (1) and one each in rare sites in Kidney and Prostate. In one patient, 2 primary sites were identified (one each in stomach and duodenum). Mean SUV max of the detected primary sites was 25.1 +/- 18.0 (median 16.25, range 2.1-150). Significant positive correlation was found between SUV max of primary tumor and histopathologically proven sites of metastasis ($r = 0.662$; $p < 0.0001$). Based on the findings of the 68Ga-DOTANOC PET/CT scan, 3 out of 40 patients underwent definitive treatment for their primary tumour (1 gastric, 1 ileal and 1 prostatic tumour). 1 patient was being planned for resection of primary rectal lesion. 32 / 68 patients were started on long acting somatostatin analogues or chemotherapy or targeted therapy. 1 patient underwent multiple cycles of peptide receptor radionuclide therapy (PRRT) using 90Y and 177Lu labeled somatostatin analogues. Conclusion: Our findings indicate that 68Ga-DOTANOC PET/CT is a promising imaging modality in patients with metastatic neuroendocrine tumours of unknown origin for detection of the primary site and in guiding their therapeutic management.

F-18 DOPA PET/CT in patients with neuroendocrine tumors

A. T. Golubic, D. Huic, A. Mutvar, M. Zuvic; Department of Nuclear Medicine and Radiation Protection, University Hospital Center Zagreb, Zagreb, CROATIA.

Aim: The aim of this study was to examine and study the impact of F-18 DOPA PET/CT imaging in patients with medullary carcinoma and other neuroendocrine tumors. Materials and Methods: Twenty patients were referred to our Department for staging or restaging neuroendocrine tumors. They were scanned with F-18 dihydroxyphenylalanine (DOPA) PET/CT from November of 2012 to January 2015. In 13 of our patients, medullary carcinoma was diagnosed at least 11 months earlier; mean period from diagnosis to PET/CT was 5 years. Other neuroendocrine tumors were diagnosed in 7 patients (three with insulinoma, two with paragangliomas, one had pheochromocytoma and in one patient undefined NET was suspected). Because of elevation of tumor markers and/or equivocal findings of morphological imaging methods (i.e. ultrasound, MSCT or MRI), functional diagnostic imaging was proposed. The mean follow up period was 11.3 months. Results: An increased abnormal F-18 DOPA uptake was found in 12 patients (60%). In 9 out of 13 medullary carcinoma patients, a positive finding was reported, mostly due to metabolically active metastases in neck and mediastinal lymph nodes. Mean SUV value was 5.5, ranging from 2.6 to 9.5. Three patients referred with other NET diagnoses had a positive DOPA PET/CT scans and were spared further diagnostic procedures and unnecessary treatments. Two patients benefited greatly from an F-18 DOPA scan, as they were completely cured after surgical resection (one with insulinoma and one more with paraganglioma). Comparing with other imaging modalities used in our patient population (CT, MR, bone scintigraphy, Octreoscan, or Tc-99m-DMSA V scintigraphy), F-18 DOPA was found to be the most sensitive in discovering various disease locations, especially for medullary carcinoma. After F-18-DOPA PET/CT scan, surgical extraction of metabolically active tissues was performed , in seven patients. Conclusions: F-18-DOPA PET/CT is a novel, still emerging molecular diagnostic imaging method for staging and restaging neuroendocrine tumors. Both positive and negative scan findings were of significant use in our patient's further management, modifying therapy options to better suit the needs of each patient individually.

Maps of serotonin transporter distribution in the human brainstem obtained using high-resolution PET correlates with post-mortem autoradiography data (ARG).

P. Fazio[1], M. Schain[1], K. Varnäs[1], C. Halldin[1], L. Farde[1,2], A. Varrone[1]; [1]Karolinska Institutet, Department of Clinical Neuroscience, Centre for Psychiatry Research, Stockholm, SWEDEN, [2]AstraZeneca Translational Science Centre at Karolinska Institutet, Stockholm, SWEDEN.

Aim. The human brainstem is a complex structure with a multitude of small nuclei and neural pathways of interest in the pathophysiology of CNS-disorders. In common with other monoaminergic systems, serotoninergic neurons originate from a group of nuclei located in the brainstem. The present study was designed to validate a methodology for in vivo quantification of radioligand binding to the serotonin transporter (5-HTT) in the human brainstem using high-resolution PET (HRRT) by comparison with post-mortem autoradiography (ARG). Methods. 3T-MR images and parametric ^{11}C-MADAM binding potential (BP_{ND}) images from 10 control subjects were used to generate a functional PET template of 5- HTT availability. An automated MR based two-step normalization procedure using various tools of the FMRIB Software Library (FSL) was employed to obtain accurate brainstem normalization. ROIs for different brainstem nuclei were defined using a threshold-based ROI-delineation method based on anatomical references and on 5-HTT availability patterns. BP_{ND} estimates in sub-cortical regions (putamen, nucleus caudatus and amigdala) were obtained by applying the AAL template. The ROIs were then transformed and applied individually to BP_{ND} images of 16 healthy subjects (14M/2F, 20-64 y). The *in vivo* distribution of BP_{ND} values was compared with the *in vitro* binding data using autoradiography studies of the human brain post-mortem and ^{3}H-MADAM as radioligand. Similar ROIs as those used in the PET study were delineated on ARG sections. Pearson correlation analysis was used to evaluate the relationship between the *in vivo* and *in vitro* binding data obtained in brainstem and sub-cortical regions. Results. The template-based method provided reliable BP_{ND} estimates in different regions of the brainstem. The highest BP_{ND} was found in the dorsal raphe (2.48±0.43), followed by the median raphe (2.20±0.47), superior colliculi (2.05±0.44), ventral midbrain (1.85±0.34) and the caudal raphe (1.12±0.18). BP_{ND} estimates obtained *in vivo* with high resolution PET in the ROIs were correlated to ($r=0.78$, $p<0.05$) the binding density (pmol/g) values obtained *in vitro* by ARG, although values for the ventral midbrain were somewhat discrepant. Conclusions. The *in vivo* distribution of 5- HTT availability in the human brainstem measured using a template-based analysis applied to HRRT-PET data was consistent with 5-HTT quantification using post-mortem ARG. The proposed template-based methodology appears to be suitable for applied studies focused on the human brainstem.

OP557

Simplified quantification of the dopamine transporter using [18F]FE-PE2I in PD patients and control subjects

I. Sonni[1,2], P. Fazio[1], M. Schain[1], C. Halldin[1], P. Svenningsson[1], L. Farde[1], A. Varrone[1]; [1]Department of Clinical Neuroscience - Karolinska Institutet, Stockholm, SWEDEN, [2]Sapienza - University of Rome, Rome, ITALY.

Introduction: [^{18}F]FE-PE2I is a novel PET radioligand for in vivo imaging of the dopamine transporter (DAT). Validated non-invasive methods for DAT quantification using [^{18}F]FE-PE2I rely on dynamic PET acquisition, but in a clinical setting a more simplified protocol consisting in one acquisition performed after tracer injection is preferable. The aim of this study was to identify the optimal acquisition time window providing the specific binding ratio (SBR) in closest agreement with the binding potential (BP_{ND}) estimated with parametric imaging. Methods: Ten Parkinson's disease patients (PD) and ten control subjects (CS) were examined with [^{18}F]FE-PE2I. A 93-min dynamic PET measurement was performed using the high resolution research tomograph (HRRT). The measurement was smoothed to the resolution of a clinical PET system (ECAT EXACT HR) to resemble a clinical setting. ROIs for caudate (CAU), putamen (PUT), ventral striatum (VS), substantia nigra (SN) and cerebellum (CER) were drawn on co-registered MR images. SBR was computed for 8 different time windows, using CER as a reference region. Linear regression analysis was used to compare the SBR to BP_{ND} values obtained with the wavelet-aided parametric imaging (WAPI) software. The optimal acquisition time window was selected using the SBR values obtained from the HRRT dynamic measurement (HRRT-SBR). The selected acquisition time window was used to create an average lower-resolution image and to measure SBR (HR-SBR), as a clinical outcome measure. Effect sizes of SBR and BP_{ND} were calculated to assess differences between CS and PD patients. Results: SBR values obtained from the HRRT that correlated best to WAPI BP_{ND} were obtained for the time window between 16.5 and 42 min (R^2 = 0.98). A significant correlation was also observed with HR-SBR (R^2 =0.95 in CS and R^2= 0.97 in PD patients). In the striatum, HR-SBR values underestimated BP_{ND} by 37%±3% in CS and by 29%±10% in PD patients, and in the SN by 22% in CS and by 14% in PD patients. Similar effect sizes for BP_{ND} and HR-SBR were found in CAU (both 0.6), PUT (1.7 and 1.4), VS (both 0.7), and SN (0.5 and 0.4). Conclusions: The optimal acquisition time window for simplified DAT

quantification using [^{18}F]FE-PE2I is between 16.5 and 42 min. Despite underestimation of BP_{ND}, and possibly decreased sensitivity to detect nigrostriatal deficit, the SBR can be viewed as a valid quantification method for DAT using [^{18}F]FE-PE2I for diagnostic purposes, since it provides similar differentiation as BP_{ND} between CS and PD patients.

OP558

Translational Imaging Improves Diagnostic Power of FP-CIT SPECT in Parkinsonian Syndrome

C. Paschetta, F. Buttari, A. Skanjeti, D. Gned, V. Podio; San Luigi Gonzaga Hospital, Orbassano (TO), ITALY.

Aim: Neurodegenerative disease incidente is forecast to increase in next years; early diagnosis could help in slowing disease progression and in avoiding side effects from incorrect treatments. Parkinsonian Syndromes (PS) are a common degenerative disorder and their early assessment requires molecular imaging with cocaine-analogue radiopharmaceuticals (FP-CIT SPECT) since symptoms are aspecific and MR imaging can identify morphological alterations that could be related to symptoms. Our aim was to detect if integration of MR can increase sensitivity, specificity and accuracy of SPECT in assessment of PS.Materials and Methods: Sixty-three subjects with suspected PS (age 66±11, 33 M) underwent both FP-CIT SPECT and brain MR imaging in a mean time of 6 months. After at least two-years neurological follow-up, PS was confirmed in 33 patients; analysis compared findings from these patients and the 30 PS-free subjects. SPM8 was used to normalize SPECT and MR images on our home-made and built-in template respectively. For each imaging modality, SPM8 analysis defined VOIs including voxels with differences between PS patients and PS-free subjects. VOIs data were extracted by SPM8 with MarsBaR toolbox. Data were evaluated by multivariate logistic regression to identify significant relationships with diagnosis.Results: At SPECT, SPM8 identified significant difference between PS patients and PS-free subjects in basal ganglia; at logistic analysis diagnostic power was good (Se=73%, Sp=90%, Acc=81%, p<0.00001).MR analysis detected differences in thalami, anterior cingulate, posterior parietal and occipital area. In all occurrences MR shows accuracy lower than SPECT; best results ware obtained from thalami (Se=79%, Sp=57%, Acc=68%, p=0.005). The integration of MR VOIs data from thalamic region in SPECT analysis improved accuracy from 81% (SPECT alone) to 89% and halved incorrect results by increasing sensitivity to 85% and specificity to 93%. Conclusion: When movement disorders occur, semi-quantitative analysis of FP-CIT is essential but not adequate for an optimized assessment. SPECT and MR integration by automatic voxel-based morphometric analysis result in a significant accuracy improvement.Translational imaging allows the development of synergies between structural and functional methods resulting in a positive impact on quality and cost of care.

OP559

Age- and sex-related differences in 18F-FDG brain metabolism in healthy subjects using a PET-driven partial volume effect correction method

S. Bonte[1,2], P. Vandemaele[2], S. Verleden[3], K. Audenaert[3], K. Deblaere[2], I. Goethals[2], R. Van Holen[1]; [1]Ghent University: MEDISIP (Department of Electronics and Information Systems), Ghent, BELGIUM, [2]Ghent University Hospital: Department of Radiology and Nuclear Medicine, Ghent, BELGIUM, [3]Ghent University Hospital: Department of Psychiatry, Ghent, BELGIUM.

Introduction: Several authors have investigated the age- and sex-related differences in ^{18}F-FDG PET scans in healthy subjects. Most authors reported a reduced metabolism in the ageing brain, especially in the frontal regions. However, when correcting for structural atrophy using a MRI-based method, some authors reported that all age-related changes disappeared, while others observed a true decreased metabolism with increasing age. The goal of our study was to apply a purely PET-driven partial volume effect correction (PVEc) method to investigate age- and sex-related differences in the healthy brain. Materials and methods: 79 carefully selected healthy subjects were enrolled in this study. They underwent, among other investigations, a ^{18}F-FDG brain PET and MRI. PET images were corrected for the intensity diffusion caused by the point spread function of the PET-scanner using a post-reconstruction iterative deconvolution method with the use of the Huber prior for denoising, as presented by B.A. Thomas (Ph.D. dissertation, UCL 2012). Both the original and corrected image are normalised to MNI-space and smoothed using SPM12. The software is also used for a voxelwise multiple regression analysis with age and sex as covariates. Results: The analysis of all subjects with sex as a covariate yields no significant clusters with more than 100 voxels at the $p < 0.05$ significance level, both before and after PVEc. There are however negative correlations between metabolism and age, which survive PVEc, especially in the frontal lobes. When the female subgroup is investigated separately, there are no clusters that survive PVEc. In the male subgroup, there are two clusters that survive PVEc, comprising (part of) the caudate and the anterior and medial part of the superior frontal gyrus and cingulate bilaterally. Discussion: Most frequently used partial volume effect correction methods rely on a co-registered and segmented MRI-image to take structural atrophy into account. These methods are prone to registration and segmentation errors and assume a uniform uptake in various brain regions. Moreover, structural and functional information are not always directly correlated. In contrast to these methods, we have used a purely PET-

driven PVEc method. Using this method, we found decreasing metabolism with increasing age in large parts of the (medial) frontal lobes. We also documented a different ageing process in women and men. The absence of clusters after PVEc in the female brain should however be interpreted with caution, because results are only borderline significant.

OP560

Age-related changes in FDG brain uptake are more accurately assessed when applying an adaptive template to the SPM method of voxel-based quantitative analysis

A. Van Der Gucht[1], **A. Verger**[1], E. Guedj[2], G. Malandain[3], G. Hossu[4], Y. Yagdigul[1], V. Roch[1], S. Poussier[1], L. Maillard[5], G. Karcher[1], P. Marie[1]; [1]CHU Nancy, Nuclear Medecine & Nancyclotep Experimental Imaging Platform, Nancy, FRANCE, [2]AP-HM, Hospital "La Timone", Department of Nuclear Medicine, Marseille, FRANCE, [3]INRIA Sophia Antipolis-Méditerranée, Sophia Antipolis, Valbonne, FRANCE, [4]INSERM, CIC-IT 1433, Nancy, FRANCE, [5]CHU-Nancy, Department of Neurology, Nancy, FRANCE.

The impact of age is crucial and must be taken into account when applying a voxel-based quantitative analysis on brain images from [18F]-fluorodesoxyglucose Positron Emission Tomography (FDG-PET). This study aimed to determine whether age-related changes in brain FDG-PET images are more accurately assessed when the conventional Statistical Parametric Mapping (SPM) normalisation method is used with an adaptive template, obtained from analysed PET images using a Block-Matching (BM) algorithm in order to fit with the characteristics of these images. Methods. Age-related changes in FDG-PET images were computed with linear models in 84 neurologically healthy subjects (35 women, 19 to 82 y-old), and compared between results provided by the SPM normalisation algorithm applied on its dedicated conventional template or on the adaptive BM template. A threshold P-value of 0.05 was used together with a family wise error (FWE) correction. Results. The age-related changes in FDG-PET images were much more apparent when computed with the adaptive template than with the conventional template as evidenced by: 1) stronger correlation coefficients with age for the overall frontal and temporal uptake values (respective R2 values of 0.20 and 0.07) and 2) larger extents of involved areas (13% and 5% of whole brain template volume respectively), leading to reveal several age-dependent areas (especially in dorsolateral prefrontal, inferior temporal/fusiform and primary somatosensory cortices). Conclusion. Age-related changes in brain FDG uptake may be more accurately determined when applying the SPM method of voxel-based quantitative analysis on a template that best fits the characteristics of the analysed TEP images.

AIM: In the last years, several semi-quantitative automatic analysis methods have been developed to analyze brain 18Fluorodeoxyglucose Positron Emission Tomography (18F-FDG-PET) data with the aim to differentiate MCI subject due to AD (MCI-AD) from MCI due to other causes. The aim of the present work was to compare the accuracy of three different methods for the identification of MCI patients due AD. The three tested methods were 1. a ROI-based analysis within SPM8, 2.PALZ score provided by PMOD 3. a new metaROI method analyzed with the support of vector machine (SVM) METHODS: Sixty-two subjects with aMCI who during follow-up have developed AD dementia (MCI-AD, months follow-up range=6-84 mean=25.43±15.64; age=72.38±8.15; education=10.22±4.37; MMSE score = 27.0±1.58) and one hundred-nine healthy subjects (CTR; age=66.8±6.51; education=11.6±3.78; MMSE score = 29.25±1.2) were enrolled in five centers of the European Alzheimer's Disease Consortium (EADC). All subjects underwent clinical-neuropsychological evaluation, structural neuroimaging and 18F FDG-PET when they were at the aMCI stage. SPM8 was used to obtain the Regions of Interest extracted from i) the comparison between CTR and MCI-AD (ROI-1) and ii) from the correlation between brain metabolism and delayed recall in the Rey Auditory Verbal Learning Test (RAVLT) in an independent group of fifty-four elderly subjects with mild cognitive decline (ROI-2 based on a previous study of our group). In fact delayed recall

impairment is a typical feature of MCI-AD. Brain metabolism within each of the two ROIs was computed and normalized on cerebellar counts. Similarly, PALZ score and SVM were used to classify the patients as MCI-AD. ROC curves were used to evaluate the accuracy of ROI-1, ROI-2, PALZ and SVM in discriminating CTR from MCI-AD. RESULTS: The accuracy values were:; ROI-1:AUC=0.826; ROI-2:AUC=0.833PALZ score: AUC=0.867; SVM: AUC=0.947. The areas under the ROC curves (AUC) were compared between each pair of classification methods by means of the z-score (according to Hanley and McNeil, 1983). SVM method gave a significantly higher AUC than the three other methods (SVM vs ROI-1 p=0.0029; SVM vs ROI-2 p=0.0019; SVM vs PALZ p=0.0187), according to FDR criterion for multiple comparisons, while the other methods were not significantly different from each other. DISCUSSION: The study confirms the high accuracy of 18F-FDG-PET for the identification MCI due to AD and also demonstrates that different accuracy values are obtained even using the same imaging biomarker but applying different metrics. A non-linear, automatic classifier based on SVM performs better than both SPM and PALZ.

OP562

Agreement of brain amyloid PET interpretation between automated diagnosis using support vector machine and visual assessment by expert readers

I. Matsunari[1], J. Komatsu[2], M. Samuraki[2], M. Noguchi-Shinohara[2], T. Hamaguchi[2], K. Ono[2], I. Kuji[3], M. Yamada[2], S. Kinuya[2]; [1]Saitama Medical University Hospital, Iruma-gun, JAPAN, [2]Kanazawa University, Kanazawa, JAPAN, [3]Saitama Medical University International Medical Center, Hidaka, JAPAN.

Aim: In clinical practice, interpretation of brain amyloid imaging often relies on visual analysis by expert readers, which is not always available. Machine-learning based pattern recognition techniques such as support vector machine (SVM) have recently been utilized to neuroimaging modalities as an aid for automatic and objective diagnosis. The aim of this study was to assess the diagnostic performance of SVM for the detection of amyloid burden on C-11 Pib PET as compared with the visual interpretation as a reference standard. Methods: A total of 108 subjects (56 patients with cognitive disorder and 52 normal subjects) underwent C-11 Pib PET and structural MRI on a single day. Each PET image was assigned amyloid positive or negative by 2 expert readers. For SVM analysis, PET images were spatially standardized using SPM8 and co-registered MRI, followed by count normalization to cerebellum. Leave-one subject out approach was applied as a cross-validation method. Results: By visual analysis, there were 47 positive and 67 negative C-11 Pib PET scans. An excellent overall agreement (105/108 scans: 97%) was obtained between SVM and visual analysis. Using the results of visual reading as a reference standard, the SVM had sensitivity, specificity, positive predictive value, and negative predictive value of 94%, 100%, 100%, and 95%, respectively. Conclusion: Our results indicate that the machine-learning based automated analysis such as SVM may serve as an accurate diagnostic alternative to visual reading by experts for the detection of brain amyloid burden using C-11 Pib PET.

OP563

Comparison of Reference Regions to Semiquantitatively Analyse 18F-Florbetaben PET Images

H. Barthel[1], S. Bullich[2], O. Sabri[1], J. Seibyl[3], V. Villemagne[4], C. Rowe[4], N. Koglin[2], A. Stephens[2], A. M. Catafau[2]; [1]Leipzig University, Leipzig, GERMANY, [2]Piramal Imaging, Berlin, GERMANY, [3]IND, New Haven, CT, UNITED STATES, [4]University of Melbourne, Melbourne, AUSTRALIA.

Aim: Recently, amyloid β (Aβ) plaque PET imaging of Alzheimer's disease (AD) became available for clinical routine application. Binary visual interpretation is the standard assessment method in this regard. This also refers to 18F-Florbetaben (FBB). Semiquantitative PET data analysis might, however, be necessary in borderline cases or for follow-up evaluation. For relative FBB uptake quantification approaches like neocortical standardized uptake value ratio (SUVR) determination, the cerebellar grey matter (CGM) has so far consistently been used as reference region (RR). This investigation aimed at comparing CGM-FBB-SUVRs with those obtained using alternative RRs. Materials and methods: Regional and composite neocortical SUVRs were determined using CGM, whole cerebellum (WC), pons (P), and cerebral white matter (WM) as RRs in scans of three FBB PET imaging studies: (a) 271 scans of the close to clinical routine FBB Phase 2 study (composite SUVRs, standard of truth (SoT): visual assessment by 5 independent readers). (b) 88 scans of the FBB Phase 3 study (SUVRs of 4 ROIs per scan, SoT: post mortem histopathology by Bielschowsky silver staining/ immunohistochemistry for neuritic and diffuse Aβ plaques). (c) 32 scans (16 subjects) of the FBB test-retest study (composite SUVRs, endpoints: test-retest variability (TRTV) and intra-class correlation (ICC)). Results: In (a), CGM-SUVRs correlated with WC-SUVRs (ρ=0.89 (95%CI: 0.87-0.91)), P-SUVRs (ρ=0.82 (0.77-0.85)), and WM-SUVRs (ρ=0.75 (0.69-0.80)). Effect sizes which ranged from 2.41 to 3.06 in (a), as well as correlation coefficients which ranged from 0.78 to 0.84 in (a) and from 0.42 to 0.60 in (b) did not differ, with overlapping CIs, for the SUVRs as obtained by the different RRs. Likewise, no significant differences were found in TRTV which ranged from 3.17 to 4.44 in (c) or ICCs which ranged from 0.95 to 0.98 in

(c) across the different RRs. Conclusion: CGM continues to be recommended as the RR of choice to analyse FBB PET scans, due to the biological advantage of not being involved in AD-related atrophy. Regional and composite neocortical SUVRs of FBB scans are, to a large extent, robust with regard to the selection of the RR. Research support: Piramal Imaging, Berlin, Germany

Selective internal radiatiotherapy (SIRT) in hepatic metastases from uveal melanoma. Treatment response in comparison to transarterial chemoembolization (TACE) with Fotemustin

H. Duan[1], G. Berzaczy[2], F. Waneck[3], M. Funovics[3], C. Hoeller[4], M. Hoffmann[1]; [1]Medical University of Vienna, Department of Biomedical Imaging and Image-guided Therapy, Division of Nuclear Medicine, Vienna, AUSTRIA, [2]Medical University of Vienna, Department of Biomedical Imaging and Image-guided Therapy, Division of General Radiology, Vienna, AUSTRIA, [3]Medical University of Vienna, Department of Biomedical Imaging and Image-guided Therapy, Division of Cardiovascular Radiology, Vienna, AUSTRIA, [4]Medical University of Vienna, Department of Dermatology, Vienna, AUSTRIA.

Aim: Uveal melanoma is a rare tumor, which metastasizes primarily into the liver. Once hepatic metastases occur, the prognosis is bleak: The median survival rate 1 year after detection is <30%. SIRT with Y-90 resin microspheres is successfully used in the treatment of primary or secondary liver tumors. This study aims to evaluate the efficacy of SIRT in hepatic metastases derived from uveal melanoma. The results concerning time to progression and overall survival are compared to a cohort of similar patients treated with Fotemustin via TACE. Methods: Hitherto we included 20 patients, who received SIRT for hepatic metastases from uveal melanoma. Imaging with CT or MRI was performed before SIRT and 6 weeks after intervention to assess tumor response and afterwards every 3 months. All patients underwent Tc-99m macroaggregated albumin SPECT/CT 1 week prior to SIRT for pretreatment evaluation. Response to treatment and progression-free survival as well as overall survival was calculated and compared to a cohort of patients suffering from the same disease in similar conditions who were treated with Fotemustin via TACE. Results: After 1 SIRT, 7 patients showed partial response (PR) with a median time to progression of 7 ± 2.9 months (range: 3 to 25 mo) and 6 patients showed stable disease with a median time to progression of 8 ± 1.9 months (range 3 - 14 mo). 5 patients showed progressive disease (PD). 10 patients died within the observation period with a mean overall survival time of 8.5 ± 3.9 months (range: 1 to 32 mo). Concerning TACE with Fotemustin, the included 21 patients required up to 6 interventions and showed a mean progression free survival of 7.3 months (3.3 - 11.3 months). Comparing to 1 intervention with SIRT, the results are quite similar, but concerning safety and adverse events, with SIRT, patients showed only minor symptoms like pain and nausea during the intervention while with TACE, patients had heavier and longer lasting symptoms like fever, pain and nausea, which required medication. Additionally, multiple interventions were required. Conclusion: With these preliminary results we could show the efficacy and safety of SIRT in hepatic metastases derived from uveal melanoma in comparison to TACE with Fotemustin. Especially concerning adverse events and quality of life, the results of SIRT were superior to TACE with equal efficacy.

OP575

Comparison of different dosimetric methods for tumor and normal tissue predicted absorbed dose calculation in liver radioembolization: preliminary results

M. FINESSI[1], E. GALLIO[2], E. RICHETTA[3], M. STASI[3], R. PELLERITO[4], R. ROPOLO[2], G. BISI[1]; [1]S.C. Medicina Nucleare U, A.O.U. Città della Salute e della Scienza, Torino, ITALY, [2]S.C. Fisica Sanitaria, A.O.U. Città della Salute e della Scienza, Torino, ITALY, [3]S.C. Fisica Sanitaria, A.O. Ordine Mauriziano, Torino, ITALY, [4]S.C. Medicina Nucleare, A.O. Ordine Mauriziano, Torino, ITALY.

AIM: Radioembolization with 90Y-microspheres is an effective treatment for unresectable hepatic malignancies. Two types of 90Y-microspheres are available: resin (SIR-Spheres®) and glass (Theraspheres®). The treatment is preliminary simulated by planar and SPECT 99mTc-MAA acquisitions to avoid gastric and lung shunt and to determine the optimal 90Y therapeutic activity. Empirical (fixed-activity, body-surface-area) and multi-compartmental methods are suggested for resin microspheres. For glass microspheres only mono-compartmental is proposed. Analysing 99mTc-MAA SPECT images, it is possible to forecast tumour and normal tissue absorbed doses: multi-compartmental MIRD or voxel dosimetry are used. AAPM (American Association of Physicists in Medicine) recommendations suggest instead planar images. The aim of this study is to compare these different methods proposed to predict absorbed doses, with discrimination between tumour and normal tissue. MATERIALS AND METHODS: Four patients were treated with glass microspheres. According to the company, the prescribed dose was 120 Gy to entire lobe. Four patients were treated with resin microspheres to the aim of 120 Gy to lesion and 40 Gy to normal liver. For both groups, the predicted tumour and normal tissue doses were calculated with three different methods. For AAPM method on planar images a ROI was drawn on the anterior and posterior images encompassing the tumour; the same ROI was moved over the normal liver. For the other methods 99mTc-MAA SPECT-TC attenuation (glass) and

99mTc-MAA SPECT-TC attenuation and scatter corrected images (resin) were employed. For MIRD compartmental two VOIs, tumour and normal liver, were drawn to estimate uptakes and volumes. For voxel based calculations SPECT 3D counts matrix was exported to perform dosimetry with a MATLAB code developed at our departments. RESULTS: For glass microspheres patients average doses were significantly lower with AAPM method compared to MIRD (tumour -28%, normal liver -86%) and to voxel (tumour -41%, normal liver -89%); high discrepancies were found also for resin microspheres: MIRD (tumour -35%, normal liver -43%) and to voxel (tumour -14%, normal liver -37%). MIRD compartmental methods compared to voxel dosimetry showed instead more comparable results with a smaller range of variation: for glass microspheres(tumour -28%, normal liver +14%) and resin microspheres(tumour +25%, normal liver +19%). CONCLUSION: AAPM method seems less accurate for dose estimation. Instead, MIRD and voxel based dosimetry are more confident each other. Dose variations can be determined by non-homogenous activity distribution with only voxel approach. This preliminary results must be confirmed by further ongoing investigation with a larger patient dataset.

OP576

Reduced lymphocyte proliferation and IFN-γproduction after Selective Internal Radiotherapy

A. Domouchtsidou[1], M. Lindemann[1], J. Best[2], J. Ertle[2], S. P. Mueller[3], S. Bedreli[2], P. A. Horn[1], A. Bockisch[3], V. Barsegian[4]; [1]Institute for Transfusion Medicine, University Hospital Essen, GERMANY, [2]Department of Gastroenterology and Hepatology, University Hospital Essen, GERMANY, [3]Department of Nuclear Medicine, University Hospital Essen, GERMANY, [4]Institute of Nuclear Medicine, Helios Kliniken Schwerin, GERMANY.

Selective Internal Radiotherapy (SIRT) is an innovative therapy with yttrium-90 radioactive glass microspheres for the treatment of hepatocellular carcinoma and colorectal liver metastases. It has been described that the use of ionized radiation leads to significant lymphocytopenia. However, the data on the effect of beta rays on the immune function remain diverse. In a recent study we have shown that radioiodine therapy in patients with thyroid carcinoma does not lead to cellular immunodeficiency, but a shift from TH-2 to TH-1 response was observed. Furthermore, the use of yttrium-90-radiolabelled somatostatin analogues (Y-90 DOTATOC) in patients with neuroendocrine tumors decreases the lymphocyte proliferation and the proinflammatory immune responses causing an immunosuppression. Unlike the above two mentioned tumor radiotherapies, where the radionuclides circulate in the bloodstream, in SIRT the yttrium-90 radioactive glass microspheres become trapped in the tumor capillary bed and leave the majority of the healthy nearby tissue intact. Nevertheless, considering the high dosage administrated and the fact that approximately 12% of the total blood volume is in the liver, an unintended low dose to the immune system is possible. The aim of our study is to gain insight into the modifications that take place following a SIRT treatment at the level of the lymphocyte proliferation as well as to identify a possible antimicrobial immunological impairment. Thus, in 20 patients treated with SIRT lymphocyte proliferation and the production of pro- and anti-inflammatory cytokines (interferon-γ and interleukin-10) after stimulation with mitogens and recall antigens are tested immediately prior to therapy and at day 1, day 2, day 7 and day 28 after therapy using lymphocyte transformation test and ELISpot. Preliminary data in 16 patients indicate that from day 1 until day 28 after therapy lymphocyte proliferation and interferon-γ production are significantly ($P < 0.05$) reduced. The most prominent finding was a pronounced reduction of anti-microbial immune responses. In conclusion, according to our current results there is a severe impairment of immune function after SIRT which seems to be more intense than after radioiodine therapy or Y-90 DOTATOC treatment.

OP577

Retrospective analysis of dose-response for HCC lesions treated with 90Y resin microspheres

C. Pettinato[1], C. Mosconi[2], A. Cappelli[2], S. Civollani[1], P. Pini[3], F. Monari[4], C. Galaverni[2], B. Angelelli[5], F. Trevisani[3], R. Golfieri[2]; [1]Medical Physics Unit - AOU di Bologna, Bologna, ITALY, [2]Radiology Unit - AOU di Bologna, Bologna, ITALY, [3]Internal Medicine Unit - AOU di Bologna, Bologna, ITALY, [4]Radiotherapy Unit - AOU di Bologna, Bologna, ITALY, [5]Oncology Unit - AOU di Bologna, Bologna, ITALY.

Aim: We retrospectively analyzed 50 patients affected by HCC and treated with 90Y resin microspheres. The aim of this study was to evaluate the correlation between tumor dose and local tumor response. **Materials and Methods**: From September 2010 to October 2014 46 patients affected by HCC have been treated with 90Y resin microspheres. All patients received an intra-hepatic infusion of 150 MBq of 99mTc-MAA to calculate lung and extra-hepatic shunts and to perform lesion and whole liver dosimetry using the MIRD formalism. The activity to be injected was calculated using the BSA formula and was modulated based on tumor and normal liver doses, limiting the dose to whole normal liver to about 30 Gy. **Results**: The mean injected 90Y activity was 1.5 ± 0.5 GBq. The mean tumor volume was 288 cc ranging from 43 cc to 2566 cc, while the average dose was 258 Gy ranging from 13 to 858 Gy. Tumors with smaller volumes received

higher doses. The average doses to tumors with volumes below 100 cc, between 100-300 cc, between 300-500 cc and above 500 cc were respectively 436 Gy (95% IC: 359.2 - 795.2 Gy), 265 Gy (95% IC: 225.7 - 490.7 Gy), 135 Gy (95% IC: 127.6 - 262.6 Gy) and 108 Gy (95% IC: 92.6 - 200.6 Gy). 24/46 patients received an average tumor dose greater than 200 Gy. Among them 10 patients showed a complete response and an average survival > 12 months. 5/24 patients had a good response at 9 months follow-up, while 9/24 patients had a worsening of the disease due to progression of non treated lesions. 7/22 patients, that received less than 200 Gy, had stable or good response of treated lesions 9 months after treatment. 6 out of these 7 patients had lesion volumes greater than 300 cc. How results suggest that big tumors (>300 cc) are responsive to lower average doses because whole tumor volume, including also "non-active" or necrotic parts typical of large lesions, is considered in the average dose calculation. **Conclusions**: Average tumor dose based on ^{99m}Tc-MAA SPECT images is a good prognostic value to predict tumor response to ^{90}Y resin microspheres treatments in patients affected by HCC. Our results showed that 42% of tumors that received more than 200 Gy had complete response while 67% of tumors had stable or good response for more than one year.

OP578

PET-CT in the post-treatment evaluation of a HCC patient treated with Yttrium-90 radioembolization

R. Stoico, L. Dellavedova, M. Carletto, L. Maffioli; A.O. Ospedale Civile di Legnano, Legnano, ITALY.

The aim of the present study was to evaluate PET-CT scan method in terms of image quality and dosimetry, in a HCC patient, treated with Y90 transarterial radioembolization (TARE). The patient underwent Y90-TARE to treat a single lesion of 52.5 cm^3. Pre-treatment planning 150 MBq Tc99m-MAA SPECT-CT scan was performed in order to calculate injection activity, tumor dose and to evaluate visceral shunt. Percentage lung shunt fraction was calculated with planar whole-body acquisitions. The planned activity was calculated by the use of compartmental method. The tumor and non-tumor doses were calculated as injected activity multiplied by 50 divided by the mass. The injected activity was 3.4 GBq; the tumor and non-tumor doses were 932 Gy and 62 Gy respectively (reference values). Therasphere (Nordion, Canada) treatment was performed. No radioprotection problem during treatment angiographic procedure for health operators was recorded. The day after the treatment PET-CT (Philips Gemini TF 16 slices, CT: 120 kV, 100 mAs, Z-DOM low dose alghorithm, PET: nuclide Y90, 15 min/bed, 2 bed positions to cover the liver) scan was performed. OSEM TOF iterative algorithm (3 iterations, 33 subsets) was used. A quantitative evaluation on reconstructed images was made by the use of Philips software. The image quality was evaluated in terms of volume definition. Tumor and non-tumor thresholds ROIs were used to calculate volumes (mm^3) and activity concentration (MBq/ml). Tumor and non-tumor doses were obtained by the use of the same dosimetric planning method. Lung shunt fraction was not considered (percentage value was zero). Percentage difference between reference and scan values for image quality and dosimetric analysis was calculated. The quantitative analysis about image quality showed percentage difference in volume calculation of -5%. The dosimetric analysis showed that calculated tumor dose was 993 Gy and non-tumor dose 52 Gy. Differences between calculated and planned dose values were +6.5% to tumor, -16.5% to non-tumor. In our experience, after Y90-TARE, PET-CT was considered the optimal scan method due to high image resolution and low time consumption. The evaluation of PET-CT scan method post-Y90 radioembolization in terms of image quality showed a comparable volume definition with reference CT by the use of threshold ROI method; in terms of dosimetry a comparable evaluation of tumor dose but an underestimation of non-tumor one. This preliminary result put in evidence the importance to perform a pre-treatment dosimetric plan because the non-tumor dose is a significant parameter to evaluate liver complications post-treatment.

OP579

Comparison of Survival, Safety and Efficacy After Chemo and Radioembolization of BCLC Stage B-C Hepatocellular Cancer Patients.

C. Soydal, M. F. Arslan, N. O. Kucuk, R. Idilman, S. Bilgic; Ankara University Medical Faculty, Ankara, TURKEY.

Aim: We aimed to compare overall survival times, long-term complication and recurrence rates of chemo and radioembolization for BCLC Stage B-C hepatocellular cancer patients. Materal and Method: 80 BCLC Stage B-C hepatocellular cancer patients who received chemo or radioembolization were retrospectively included to the study. Overall survival times, long-term complication and disease recurrence rates of two groups were compared. Additionally prognostic role of gender, age, presence of underlying chronic liver disease, BCLC stage, dimension and number of liver lesions, tumor load and presence of extra-hepatic disease for each group were analyzed. Results: 40 (27M and 13F; mean age: 41.9±21.9) patients were analyzed in each group. During follow-up period, twenty-two and 30 patients were died in radio and chemoembolizations groups, respectively. Overall mean survival of whole patient group was calculated as 37.31±3.94 months (30.46-44.1, %95CI). It was 30.63±3.68 months (23.42-37.84, %95CI) for chemo and 39.24±4.62 months

(30.18-48.29, %95CI) for radioembolization groups, respectively (p=.0.014). One and two years survival rates were 72% vs 74% and 47% vs 59% for chemo and radioembolization groups. There was no significant difference between chronic complication (p=0.32) and disease recurrence (p=0.65) rates of groups. While dimension of the largest lesion was the most significant predictor (p=0.01) in radioembolization group, female gender (p=0.008), dimension of the largest lesion (p=0.03) and BCLC stage (p=0.01) were significant for chemoembolization group. Conclusion: While chemo and radioembolization for BCLC Stage B-C patients are similar in safety and efficacy, they differ in overall survival. Patients seem to live longer after radioembolization. The dimension of the largest liver lesion is predictor for both treatments. Additionally gender and BCLC stage are significant factors in chemoembolization group.

OP580

Safety of 90Y-glass microspheres therapy in hepatic malignancies, our experience.

P. Borrelli, P. Bello Arqués, P. Olivan Sasot, C. Igua Sáenz, V. Vera Pinto, J. Vercher-Conejero, J. Loaiza Góngora, C. Ruiz Llorca; Hospital Universitario y Politecnico La Fe, Valencia, SPAIN.

AIM: To follow-up clinically patients with hepatocellular carcinoma and/or unresectable liver metastasis, treated with 90Y glass microspheres using intraarterial hepatic radioembolization, and describe immediate (less then 24 hours after treatment) and later complications onset. Materials and methods: Between April 2009 and January 2015, 54 treatments were performed in 49 patients (36 men/18 women), medium age 58.22 years (28-85). 43 treatments were carried out due to hepatocellular carcinoma, 5 neuroendocrine tumor metastasis, 2 colonic carcinoma metastasis, 2 medullary thyroid carcinoma metastasis and 2 cholangiocarcinoma. Prior to treating patients a simulation study was performed using 99mTc-albumin macroagregates (99mTc-MAA), through the same tumor nurturing arterial vessel. Bremsstrahlung images were acquired in every post-treatment, to evaluate radiopharmaceutical distribution and extrahepatic leaks, if any. Since May 2013 (34 patients) were also evaluated using PET/CT. All patients received prophylactic treatment including oral steroids and proton bomb inhibitor. Results: Average follow-up was 13.65 months, during this period 30 patients (55,5%) died due to underlying disease complications. In just one case extrahepatic leak was found in the gallbladder walls, although no symptoms were shown afterwards. At the 99mTc-MAA pre-treatment test, medium pulmonary shunt was 5,58% (0.03-34.5) and gastrointestinal leak 2,12% (0-4.8). 90Y-glass microspheres medium dose administered was 2.86GBq (0.55-6.42) At the first 24 hours after radiopharmaceutical administration only 3 cases (5.55%) presented complications, two of them pain in the right hypochondrium and one cirrhotic decompensation. Eight patients (14.8%) presented asthenia and/or fever during the first month after treatment, probably due to radioembolization although it could represent symptoms associated with the underlying disease. Conclusion: Hepatic methastasic or tumoral radioembolization has proven to be a safe palliative therapy, without immediate major secondary effects. Late and non-specific secondary effects are being studied to, if feasible, identify its origin, due to the underlying progressive disease or due to late therapy effects.

OP581

Yttrium-90 Radioembolisation for Colorectal Cancer Liver Metastases: Circulating Angiogenic Factors and Treatment Response

C. E. N. M. Rosenbaum; University Medical Center Utrecht, Utrecht, NETHERLANDS.

Aim: Yttrium-90 radioembolisation (^{90}Y-RE) of liver metastases results in radiation damage and hypoxia in liver tissue, which is a powerful trigger for the systemic release of angiogenic factors that stimulate angiogenesis and may enable (extra hepatic) tumour growth. Our aim was 1) to investigate predictive value for response of baseline values of several angiogenic factors, and 2) to examine changes in serum levels of these factors following ^{90}Y-RE. Materials and Methods: A prospective cohort study was conducted in 42 patients with unresectable colorectal cancer liver metastases, refractory to systemic therapy. Blood samples were taken at baseline, and at 0, 1, 3, 7 and 30 days after treatment. Response was measured with MR and FDG-PET imaging, at baseline, one and three months after treatment and subsequently at three-month intervals until progressive disease. Angiogenic factors included vascular endothelial growth factor (VEGF), hepatocyte growth factor (HGF), angiopoietin-2, basic fibroblast growth factor (FGF-b), platelet-derived growth factor (PDGF-BB), stromal cell-derived factor 1 (SDF-1a) and thrombospondin-1. Results: Thirty patients had liver only disease and 12 patients had limited extrahepatic disease (EHD). Patients were treated with whole liver / one session resin ^{90}Y-RE (median administered activity 1.5 GBq per BSA method). Median overall survival was 9.2 month (95%-confidence interval 6.0 - 12.4 months). Median time to progressive disease of liver lesions was 3.0 months, with a significant difference between patients with versus without EHD at baseline (1.4 versus 3.5 months; p=0.001). At three months follow up, 22 patients showed progressive disease of liver lesions, which was caused by occurrence of new lesions in 19 patients and in only 3 patients by growth of baseline lesions. Baseline serum levels of several angiogenic factors varied considerably among patient groups, e.g. higher baseline levels of angiopoietin-2 and HGF were observed in patients with kRAS mutation as compared to patients without this

mutation, suggesting differences in tumour biology and behaviour. Furthermore, heterogeneity was also seen in responders versus non-responders, for example lower baseline values for serum VEGF were seen in patients with partial response at three months follow up. Several patterns of changes in angiogenic serum levels were observed, with 10/42 patients showing a distinct peak in e.g. VEGF at 7 days after treatment. Conclusion: Our findings suggest that even in this macroscopically homogenous patient group, tumour biology may vary considerably among individuals, and should be weighed carefully for individualized treatment.

The use of radiocobalt as a label improves PET imaging of EGFR using DOTA-conjugated affibody molecules.

J. Garousi[1], K. Anderson[2], J. H. Dam[3], B. B. Olsen[3], A. Orlova[4], J. Buijs[1], S. Ståhl[2], H. Thisgaard[3], V. Tolmachev[1]; [1]Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, SWEDEN, [2]Department of Protein Technology, KTH - Royal Institute of Technology, Stockholm, SWEDEN, [3]Department of Nuclear Medicine, Odense University Hospital, Odense, DENMARK, [4]Department of Medicinal Chemistry, Uppsala University, Uppsala, SWEDEN.

Aim. Epidermal growth factor receptor (EGFR) is the molecular target for monoclonal antibodies cetuximab and panitumumab, and tyrosine kinase inhibitor gefitinib. Radionuclide molecular imaging of epidermal growth factor receptor (EGFR) expression might facilitate stratification of patients for EGFR-targeting therapies. We have demonstrated earlier that 111In-labelled anti-EGFR DOTA-ZEGFR:2377 affibody molecule can image specifically EGFR-expressing xenografts. This affibody molecule has similar affinity to both murine and human EGFR. The use of PET may further improve sensitivity of EGFR imaging. We evaluated two positron-emitting nuclides, 68Ga (T½=67.7 min) and 55Co (T½=17.5 h min) as labels. The aim of this study was to evaluate influence of radiogallium and radiocobalt labels on biodistribution of DOTA-ZEGFR:2377. Materials and methods. 55Co was produced by the 54Fe(d,n)55Co nuclear reaction using isotopically enriched target and separated from target material using anion exchange on Dowex 1x8. 57Co was used as a surrogate for 55Co in some experiments. Conjugates were evaluated in vitro using EGFR-expressing A431 cells. In vivo studies were performed in BALB/C nu/nu mice bearing A431 xenografts. The injected dose of all conjugates was 40 μg/mouse. Results. DOTA-ZEGFR:2377 was labelled with 68Ga and with radiocobalt with yields >98%. Both 68Ga- and 55/57Co-labelled DOTA-ZEGFR:2377 demonstrated specific binding to A431 cells in vitro. IC50 values were 0.58±0.19, 0.70±0.15, and 0.53±0.15 pM for natGa, natIn, and natCo-loaded DOTA-ZEGFR:2377, respectively. Biodistribution of 68Ga-DOTA-ZEGFR:2377 resembled biodistribution of 111In-DOTA-ZEGFR:2377. At 3 h pi, uptake of 68Ga-DOTA-ZEGFR:2377, in tumour, blood and liver was 2.7±0.1, 0.42±0.9, and 6.2 ±0.3%ID/g, respectively. In the case of 57Co-DOTA-ZEGFR:2377, the tumour uptake was increased to 5.8±0.6%ID/g, and liver uptake decreased to 1.85±0.6%ID/g. The blood concentration was 0.48±0.02 ID/g. Tumour-to-blood and tumour-to liver rations were 7±2 and 0.44±0.03 for 68Ga-DOTA-ZEGFR:2377, and 12±2 and 3.1±0.5 for 57Co-DOTA-ZEGFR:2377. At 24 h pi, the tumour-to-blood ratio for 57Co-DOTA-ZEGFR:2377 increased to 32±7. The biodistribution data were confirmed by in vivo imaging. Conclusion. The use of radiocobalt improves targeting properties of anti-EGFR affibody molecules DOTA-ZEGFR:2377. The exact nature of this phenomenon is not quite clear for us. We can speculate that the hepatic uptake of anti-EGFR affibody depends on both EGFR expression in liver and properties of the molecule. The use of divalent cobalt instead of trivalent gallium or indium increases a negative charge at C-terminus. This might reduce hepatic uptake and makes more tracer available for tumour targeting.

OP583

223Ra-NaA-silane-PEG-SP(5-11) radiobioconjugate as a new potential radiopharmaceutical for targeted α therapy of glioblastoma multiforme

A. Majkowska-Pilip[1], P. Koźmiński[1], A. Piotrowska[1], F. Bruchertseifer[2], A. Morgenstern[2], M. Bonelli[3], M. Laurenza[3], A. Bilewicz[1]; [1]Institute of Nuclear Chemistry and Technology, Warsaw, POLAND, [2]European Commission, Joint Research Centre, Institute for Transuranium Elements, Karlsruhe, GERMANY, [3]Dept. Physiology and Pharmacology, Sapienza University of Rome, Rome, ITALY.

Aim: Despite all current forms of treatment such as advanced surgery techniques, radiation therapy and chemotherapy, the life expectancy of patients diagnosed with glioblastoma multiforme (GBM) is 12 to 15 months displaying the worst median overall survival among all human neoplasms. According to the cancer stem cell hypothesis, malignant gliomas arise from mutated, developmentally arrested multipotent progenitor cells ("glioma stem cells") that sustain tumor growth and are intrinsically resistant to radio- and chemotherapy. Targeted alpha therapy has been shown to overcome chemo- and radioresistance in vitro and thus presents a promising approach for therapy of GBM. The aim of this study is to investigate the use of radiobioconjugate - 223Ra-NaA-silane-PEG-SP(5-11) for targeted α therapy of gliomas. Materials and methods: Sodium form of an A type of nanozeolite (NaA) was

synthesized using the hydrothermal method. Size distribution and shape of NaA nanozeolite particles were characterized by dynamic light scattering analysis (DLS), scaning elektron microscopy (SEM) and transmission emission spectroscopy (TEM). PEG linker (2000 kDa) comprising the silane group at one end and N-succinimid ester (NHS) at the second was used for synthesis of silane-PEG-SP(5-11) bioconjugate. The obtained bioconjugate was characterized by thermogravimetric (TGA) and DLS analysis. Next the NaA-silane-PEG-SP(5-11) bioconjugates were labelled with 223Ra by exchange of Na+ cation and stability of obtained radiobioconjugates were tested in various biological fluids. Cell viability was assayed using the MTS colorimetric assay. Results: Nanosized zeolites were successfully prepared through hydrothermal synthesis. The TGA results has shown that silane-PEG-SP(5-11) molecules are covalently attach to the NaA nanozeolite surface. 223Ra α-particle emitting radionuclide, has been absorbed in the nanometer-sized NaA zeolite (30-70 nm) trough simple ion exchange. The 223Ra labeled nanozeolite bioconjugate successfully retain 95% fraction of the daughter products without compromising the tumoricidal properties of the radiation. It is worth to notice, that the release of the decay product from 223Ra is a negligible problem, because 75% of the α-particles energy are emitted within a 4 seconds after the 223Ra decay. Cytotoxicity assays showed a reduction of viability of GBM cells as well as GBM stem cells after incubation with 223Ra-NaA-silane-PEG-SP(5-11) in a dose dependent manner. Cell viability also decreased with increasing incubation times. Conclusion: Targeted alpha therapy with 223Ra-NaA-silane-PEG-SP(5-11) is a promising approach for treatment of GBM which is resistant for conventional therapies and warrants further investigation in vivo.

Zipper[3]; [1]Institute of Nuclear Chemistry and Technology, Warsaw, POLAND, [2]Heavy Ion laboratory, University of Warsaw, Warsaw, POLAND, [3]Institute of Physics, Department of Nuclear Physics, University of Silesia, Katowice, POLAND.

Aim: The ^{211}At might be a particularly useful radionuclide in targeted radiotherapy, as it decays by the emission of short-range high-energy α-particles. However, many astatine compounds that have been synthesized are unstable *in vivo*, providing motivation for seeking other ^{211}At labeling strategies. In our work we propose to utilize formation of strong bond between metallic gold and astatine to bind the ^{211}At to biomolecules. Materials and methods: The gold nanoparticles with diameter of 2 and 20 nanometers were synthesized by Turkevich and Brust-Schiffrin methods. All types of the nanoparticles were characterized by TEM technique. The average particle size in solution and zeta potential were determined by DLS technique. The obtained gold nanoparticles were conjugated to substance P - short peptide having high affinity to NK1 receptors on the glioma cells. In first step polyethylene glicol with disulfide or thioctic acid with N-succinimidyl ester as a linkers were conjugated with substance P. After twenty four hours product was purified, lyophilized and spontaneously bound to gold nanoparticles. The synthesis of the bioconjugate was monitored by HPLC technique. The Au-PEG-SP bioconjugates were labelled with ^{211}At produced in cyclotron at the Heavy Ion Laboratory, University of Warsaw. Before labeling astatine was reduced to At^- using 0.01 M Na_2SO_3 solution. Stability of the obtained radiobioconjugates were tested in biological fluids: sodium chloride, cysteine, glutathione and human serum for 2, 4 and 19 hours. Results: The Au- PEG-SP (5-11) bioconjugates were successfully synthesized. The HPLC analysis has shown that thiol-PEG-N-Substance P bioconjugate are covalently attached to the gold surface. using the thiol approach. ^{211}At, α-particle emitting radionuclide, has been strongly absorbed in the ^{211}At-Au-PEG-SP bioconjugates. The bioconjugates nearly quantitatively retains the ^{211}At in all solutions studied. Less than 0.1% of the ^{211}At radioactivity was found in solution. Also preliminary in-vitro biological studies indicate that ^{211}At-labeled bioconjugates exhibit high cytotoxicity to glioma cells. Conclusion: We have shown that gold nanoparticles labelled with ^{211}At and functionalized with substance P presents a prospective solution for the use of the ^{211}At as a therapeutic tool for targeting glioma cells. This work was supported by National Science Center of Poland (Grant 011/01/M/ST406756).

OP585

Synergistically Enhanced Tumor Uptake via Dual-Targeting of CD105 and EGFR Using a "Click" Heterodimer

R. Hernandez, H. Luo, H. Hong, S. A. Graves, R. J. Nickles, W. Cai; University of Wisconsin-Madison, MADISON, WI, UNITED STATES.

Objective: Dual-targeting is expected to give higher targeting efficacy/specificity. Herein we designed and synthesized a heterodimer using 2 antibody Fab fragments (i.e. Cetuximab Fab and TRC105 Fab) for dual-targeting of the epidermal growth factor receptor (EGFR) and CD105. Expression of EGFR was mostly on the tumor cells, whereas expression of CD105 was primarily on the actively proliferating tumor vasculature. The synergistic dual-targeting effect of Cetuximab Fab-TRC105 Fab vs. single-targeting Fab (i.e. Cetuximab Fab or TRC105 Fab) was comprehensively compared in vitro and in vivo. Methods: Cetuximab Fab-TRC105 Fab (i.e. heterodimer) was synthesized by mixing Cetuximab Fab-tetrazines and TRC105

Fab-trans-cyclooctenes via Click chemistry. It was purified by HPLC with Sephacryl S-100 HR column, conjugated to 2-S-(4-isothiocyanatobenzyl)-1,4,7-triazacyclononane-1,4,7-triacetic acid (p-SCN-Bn-NOTA) and labeled with ^{64}Cu for positron emission tomography (PET) imaging. Dual-receptor binding studies were performed in U87MG human glioblastoma cells (expressing both EGFR and CD105) and tumor-bearing mice. Blocking experiments and ex vivo histology studies were performed to confirm the in vivo results. In addition, optical imaging using near-infrared fluorescent dye labeled heterodimer was also investigated for optical image-guided tumor resection. Results: Purified Cetuximab Fab-TRC105 Fab was confirmed by SDS-PAGE (~100 kDa band), whereas the two Fab fragments were at ~50 kDa. Flow cytometry studies showed much higher fluorescence signal for the hetorodimer when compared with each Fab alone. In U87MG mice, ^{64}Cu-NOTA-Cetuximab Fab-TRC105 Fab had significantly higher tumor uptake (32.0±6.9, 47.5±6.7, 46.0±3.3 and 44.1±9.4 %ID/g at 3, 15, 24, and 36 h post-injection, respectively; n=3) than that of ^{64}Cu-NOTA-Cetuximab Fab and ^{64}Cu-NOTA-TRC105 Fab (<15%ID/g for both). Blocking studies using either Cetuximab or TRC105 both led to significantly reduced U87MG tumor uptake of ^{64}Cu-NOTA-Cetuximab Fab-TRC105 Fab, confirming that the very high tumor uptake of ^{64}Cu-NOTA-Cetuximab Fab-TRC105 Fab was indeed due to dual-targeting of EGFR and CD105 in the tumor tissue (both tumor vasculature and tumor cells). Furthermore, low liver and kidney uptake was observed for the heterodimer (<10 %ID/g), which gave excellent tumor-to-normal tissue ratio. In addition, ^{64}Cu-NOTA-Cetuximab Fab-TRC105 Fab was able to non-invasively detect small tumor nodules of <20 mg in size by PET, and fluorescently labeled Cetuximab Fab-TRC105 Fab was successfully employed for optical image-guided tumor removal. Conclusions: Successful dual-targeting of EGFR and CD105, via a "click" heterodimer of 2 Fab fragments, leads to synergistic enhancement of tumor uptake over either Fab alone which could improve future cancer diagnosis and therapeutic efficacy.

OP586

Affibody-based bioorthogonal chemistry-mediated radionuclide pretargeting: proof-of-principle.

M. Altai[1], M. Tsourma[1], B. Mitran[2], H. Honarvar[1], A. Perols[3], M. Robillard[4], R. Rossin[4], W. ten Hoeve[5], M. Sandström[6], A. Orlova[2], A. Eriksson Karlström[3], V. Tolmachev[1]; [1]Department of Immunology, Genetics and Pathology, Uppsala, SWEDEN, [2]Preclinical PET Platform, Uppsala, SWEDEN, [3]Division of Protein Technology, KTH, Stockholm, SWEDEN, [4]Tagworks Pharmaceuticals, Eindhoven, NETHERLANDS, [5]Syncom B.V., Gröningen, NETHERLANDS, [6]Akademiska sjukhuset, Uppsala, SWEDEN.

Aim: The use of radiometal-labelled affibody molecules in targeted radionuclide therapy is hindered by the high uptake and retention of radioactivity in the kidneys. Commonly used methods for reduction of renal radioactivity were inefficient in the case of affibody molecules. Pretargeting is an efficient approach to improve biodistribution profiles. One promising approach is the use of bioorthogonal chemistry based on a reaction of trans-cyclooctene (TCO) and radiolabeled tetrazine. We propose affibody-based TCO-tetrazine mediated pretargeting for the reduction of renal uptake. Radiometal-labelled tetrazine clears rapidly from normal tissues including kidneys. The fast blood clearance and slow internalization rate of affibody molecules should allow sufficient TCO tags to be available on the surface of cancer cells at the time of tetrazine injection. If proven, the use of affibody-TCO/Tetrazine based pretargeting would give higher tumour-to-kidney uptake of radioactivity. This will permit the use of affibody molecules in radionuclide therapy. Methods: The maleimido-derivative of TCO was conjugated to the anti-HER2 affibody molecule, Z2395 through site-specific thiol directed chemistry. The conjugate was labelled with 125I. Tetrazine-DOTA was labelled with indium-111 in 0.25M acetate pH, 5.5 (n=6). Binding specificity to and cell retention by HER2-expressing cells of 125I-Z2395-TCO was studied. The feasibility of in vivo pretargeting of HER2-overexpressing SKOV-3 ovarian carcinoma xenografts in Balb/C nu/nu female mice was studied. For this mice were injected with 30μg (4.1nmol) 125I-Z2395-TCO followed by the injection of equimolar concentration of 111In-tetrazine, 4h later. Mice were then dissected at 1h p.i. of 111In-tetrazine. Control experiments included pre-saturation of HER2 in xenografts and injection of tetrazine without preinjection of Z2395-TCO. Results: Tetrazine-DOTA was labelled with indium-111 with a yield of 99.3 ±0.4% (n=5). 125I-Z2395-TCO bound specifically to HER2 (KD=45±16pM) and showed high cellular retention up to 24h. The uptake of 125I-Z2395-TCO in tumour xenografts was high (17±2 %ID/g at 5 h p.i.) and HER2-specific. Tumour uptake of 111In-tetrazine 1h after the injection was 60-fold higher for the pretargeted (9.7±1.6 %ID/g) than the non-pretargeted group (0.16 ±0.02%ID/g). The tumour uptake was reduced (2.9 ±0.4%ID/g) when mice were injected with large excess of non-labelled-tetrazine, suggesting specificity of TCO/tetrazine-reaction. Kidney uptake in pretargeted group was 57-fold lower compared to the previously studied 111In-labeled affibody molecule, 111In-DOTA-Z2395 (5 ±2 vs. 284±22%ID/g). The tumour-to-kidney ratio exceeded two. Gamma-camera imaging performed at 1h post-111In-tetrazine injection showed that the tumour is the only site with prominent accumulation of radioactivity. Conclusion: This study provides proof-of-principle for bioorthogonal chemistry mediated affibody-based pretargeting.

OP587

Technetium-99m radiolabeled aptamer as a potential agent capable of identifying tumor in vivo

L. KANG; PEKING UNIVERSITY FIRST HOSPITAL, BEIJING, CHINA.

Aim: Aptamers are small molecule DNA or RNA fragments that fold into well defined 3D structures with high specificity and affinity towards target molecules. Aptamers are emerging as a new class of molecules for radiopharmaceutical development. In this study a new tumor-targeted agent of radiolabel aptamer with technetium-99m (99mTc) was developed, and further its distribution and imaging in breast tumor bearing mice.Materials and methods: We used AS1411 in this study, a DNA aptamer specifically binding to nucleolin that is overexpressed on the plasma membrane of multiple cancer cells. The six carbon amine group was linked at the end of AS1411 so that the aptamer was radiolabeled with 99mTc via the conjugation to NHS-MAG3. Radiochemical purity and stability were evaluated by HPLC. Cellular uptake assays were carried out in the MCF-7 cell line to evaluate tumor uptake in vitro. MTT assay was used to assess the anti-cancer ability in vitro. Moreover, in vivo imaging of 99mTc radiolabeled aptamer were performed in breast cancer tumor models.Results: Aptamer AS1411 was successfully labeled with 99mTc in high radiochemical yields, showing high stability in the mixture of fresh human serum. In cellular uptake assay, the radiolabeled aptamer showed significantly higher uptake in MCF-7 cells than 99mTc-pertechnetate. 99mTc radiolabeled aptamer showed strong inhibitory ability in tumor cell lines, whereas 99mTc-pertechnetate had no inhibition by MTT assay. After the system administration, the in-vivo imaging results revealed the significant difference between radiolabeled aptamer and 99mTc-pertechnetate in MCF-7 tumor bearing mice, which suggested the specific binding and tumor detective ability of radiolabeled aptamer in vivo.Conclusion: The tumor-targeted aptamer directly labeled with 99mTc could be considered a promising agent capable of identifying tumor in vivo.

OP588

89Zr-Affibody for specific detection of EGFR expression in HNSCC

T. Burley, C. D. Martins, C. Da Pieve, R. L. Paul, D. M. Ciobota, G. Smith, K. Harrington, G. Kramer-Marek; The Institute of Cancer Research, Sutton, UNITED KINGDOM.

Aims: Although, present in normal cells, epidermal growth factor receptor (EGFR) is overexpressed in many human malignancies including head and neck squamous cell carcinoma (HNSCC). Clinical findings suggest that elevated levels of EGFR expression indicate poor prognosis and reduced survival in HNSCC patients. So far, EGFR-targeted agents have only had limited success as monotherapies. Therefore, identifying the presence of the molecular target is crucial in achieving an optimal outcome with molecularly targeted drugs. In this study, we have focused on strategies to develop and characterise a potential molecular imaging agent for *in vivo* quantification of EGFR expression.Materials and Methods: $Z_{EGFR:3115}$Affibody molecules were conjugated to desferrioxamine (DFO) and labelled with ^{89}Zr. *In vitro* radioligand binding specificity and affinity was evaluated by a panel of HNSCC cells expressing different levels of EGFR. *In vivo* studies were conducted in NCr nude mice bearing subcutaneous EGFR+ve HNSCC tumours. Mice were injected with 1-5 μg (2-5 MBq) of ^{89}Zr-$Z_{EGFR:3115}$Affibody. For biodistribution studies, mice bearing CAL27 (EGFR+++) and Detroit 562(EGFR+) tumours were sacrificed 1, 3, 24, 48hr following the administration of the radioconjugate spiked with 0 or 10 μg of nonradioactive $Z_{EGFR:3115}$Affibody. Selected organs were dissected and their radioactivity measured using a γ-counter. The i*n vivo* imaging profile of ^{89}Zr-$Z_{EGFR:3115}$Affibody was further investigated with a spiked dose at 3, 24 and 48hr post radioligand injection. The EGFR expression and distribution of the tracer was assessed *ex vivo* by IHC and autoradiography.Results: *In vitro* assay confirmed high-affinity binding of the ^{89}Zr-$Z_{EGFR:3115}$Affibody probe to CAL27 cells (K_d = 6.4±0.64 nM). Pre-incubation with non-labelled Affibody inhibited the binding of the radioconjugate to the cells in a dose-dependent manner. *In vivo* studies showed high accumulation of the radioactivity in CAL27 tumours (spiked with 10 μg) as early as 1 hr post tracer injection (%ID/g = 5.2). Tracer was eliminated quickly from the blood and normal tissues, producing high tumour-to-blood and tumour-to-muscles ratios (24hr: T/B = 8.5; T/M = 18.5). As expected, the highest normal tissue concentration of radioactivity was seen in the kidneys. Very good correlation was observed between PET and *ex vivo* estimates of tracer concentration and the receptor expression in the tumour tissue, as assessed by radioactivity accumulation and IHC respectively.Conclusion: Our results suggest that the described ^{89}Zr-$Z_{EGFR3115}$Affibody may be used to assess different levels of EGFR expression *in vivo*.

OP589

Strategies for the development of high specific activity affibody based probes for the detection of HER3 positive tumours

C. Da Pieve[1], L. Allott[1], C. D. Martins[1], L. Carroll[2], R. L. Paul[1], E. O. Aboagye[2], G. Kramer-Marek[1], G. Smith[1]; [1]Institute of Cancer Research, London, UNITED KINGDOM, [2]Imperial College London, London, UNITED KINGDOM.

Background: Human epidermal growth factor type 3 (HER3) is a transmembrane receptor of which expression in breast cancer is associated with a more resistant phenotype and poor prognosis. PET imaging of HER3 expression could aid in the identification of patients who could benefit from HER3-targeted therapy. Imaging HER3 is challenging due to modest over-expression of the receptor (typically <40,000 receptors/cell). Therefore, the development of affibody based tracers, exhibiting high target affinity and high specific activities, are necessary to image and quantify HER3 expression in vivo.Materials and Methods: An anti-HER3 affibody (ZHER3:8698, AffibodyAB, Sweden) was used as high affinity targeting molecule. Radiolabelling strategies, including the use of various radioisotopes (18F, 68Ga, and 89Zr) and chemistries, ([18F]AlF and inverse-electron demand Diels-Alder (IEDDA)), have been investigated in order to produce high specific activity products and limit thermal degradation of the protein. The stability and affinity for the HER3 receptor were tested in vitro using MCF7 breast cancer cells.Results: The affibody conjugates NOTA-ZHER3:8698 and DFO-ZHER3:8698 were synthesized, purified and radiolabelled with 18F and 89Zr respectively. The specific activity of these affibodies as [18F]AlF-NOTA and 89Zr-DFO conjugates were 0.8 MBq/μg (7.8 GBq/μmol) and 2.8 MBq/μg (22 GBq/μmol) respectively. Using the IEDDA reaction between tetrazine and trans-cyclococtyne, exemplified using 68Ga and 18F, resulted in a specific activity of 2.5 MBq/μg (20.8 GBq/μmol) for the 68Ga-DOTA-tetrazine and no labelling for the [18F]AlF-NODA-tetrazine reacted with TCO functionalized affibody. However, the reaction of [18F]AlF-NODA-TCO with the tetrazine functionalized affibody improved the specific activity of the product to 2.5 MBq/μg (20.8 GBq/μmol). All tracers were isolated with a RCP >97% and their binding affinities to HER3 were determined to be in the subnanomolar range (ca 0.44 nM).Conclusions: The labelling of the HER3 targeting affibody, using either a long lived radioisotope as 89Zr or a labelling strategy as IEDDA, could produce high specific activity tracers enabling the in vivo detection of HER3 positive tumours. Moreover, the developed IEDDA synthetic strategies can be applied to radiolabel other molecules allowing moderately expressed targets to be imaged.

Identification of biomarkers including ^{18}FDG-PET/CT for early prediction of response to neoadjuvant chemotherapy in Triple Negative Breast Cancer

O. Humbert[1,2], J. Riedinger[1], C. Charon-Barra[1], A. Berriolo-Riedinger[1], I. Desmoulins[1], V. Lorgis[1], S. Kanoun[1,2], C. Coutant[1], P. Fumoleau[1], F. Brunotte[1,3,2], A. Cochet[1,2]; [1]Centre Georges-François Leclerc, DIJON, FRANCE, [2]Université de Bourgogne, UMR CNRS 6306, Dijon, FRANCE, [3]Centre Hospitalo-Universitaire, Dijon, FRANCE.

Purpose: To investigate the value of metabolic and perfusion parameters, derived from ^{18}F-fluorodeoxyglucose positron emission tomography (FDG-PET) exams, compared with clinico-biological markers to predict pathological complete response (pCR) to neoadjuvant chemotherapy (NAC) in women with triple-negative breast cancer (TNBC). Material and methods: Fifty consecutive women with TNBC and an indication for NAC were prospectively included. Different pre-treatment clinical, biological and pathological biomarkers, including SBR grade, the Ki-67 proliferation index, androgen receptor expression, epidermal growth factor receptor (EGFR) and cytokeratin 5/6 staining, were assessed. Tumor glucose metabolism at baseline and its change after the first cycle of NAC (ΔSUV) were assessed using FDG-PET. Changes in blood flow (ΔBF) were measured with FDG-PET using a dynamic first-pass model. Results: The pCR rate was 42%. In univariate analysis, a high Ki-67 proliferation index (p=0.03), negative EGFR status (p=0.04), high tumor ΔBF (p=0.02) and ΔSUV (p=0.001) were predictors of pCR. Tumor ΔSUV was the most accurate biomarker to predict pCR (threshold=-60%; PPV=80.0%; NPV=75.9%; accuracy=77.3%). In multivariate analysis, both negative EGFR status (Odds ratio=9.3; p=0.034) and high ΔSUV (Odds ratio=6.8; p=0.049) were independent predictors of pCR. Combining these two parameters could predict non-pCR with an accuracy of 92%. Conclusion: It is important to define the chemosensitivity of TNBC to NAC early. Combining EGFR status and the metabolic response assessed with FDG-PET can help the physician to predict early the probability of achieving pCR or not. Given these results, the interest of response-guided tailoring of the chemotherapy might be tested in multicenter trials.

OP591

Fusion of prone FDG PET/CT and MRI improves staging of patients with breast cancer

M. J. Ribelles, M. Rodriguez, L. Sancho, F. Guillen, L. J. Pina, M. Idoate, F. Martinez Regueira, M. Santiesteban, J. A. Richter, M. J. Garcia-Velloso; CLINICA UNIVERSIDAD DE NAVARRA, PAMPLONA, SPAIN.

Objective: To analyse the value of prone FDG-PET/CT, Magnetic Resonance Imaging (MRI), and PET/MRI fused images in preoperative staging of patients with newly diagnosed breast cancer. Material and Methods: From November 2012 to February 2015, 61 patients (mean age 52 ± 11 years) with histologically proven breast cancer were included. MRI and FDG PET/CT thoracic scans were performed with the patient in prone position using the same MRI breast array coil. FDG PET/CT was performed with point spread function (PSF) and time of flight (TOF). Both studies were reviewed independently, and fused PET/MRI images were evaluated by consensus. The quality of fused PET/MRI images was scored as excellent (full coincidence), acceptable (<10 mm displacement) or poor. The histopathology was the reference standard. Sensitivity, specificity, PPV, NPV and accuracy for each technique and for PET / MRI fusion images were calculated. Results: Lesions' mean diameter on MRI was 23±17 mm (range 3.5-84 mm). On histopathology, 102 out of 142 (75%) lesions were malignant, 5 patients had bilateral disease, 47 tumours were focal, 13 tumours were multifocal, and 6 tumours were multicentric. Clinicopathologic subtype was available in 61 patients, and luminal was the most common subtype (43 patients, 70.5%), followed by 7 HER2 (11.5%) and 11 triple negative (18%). The quality of fused PET/MRI images was excellent in 37 (61%) cases, acceptable in 16 (26%) cases, and poor in 8 (13%) cases. Sensitivity, specificity, PPV, and NPV of MRI were 95%, 55%, 84%, 81% respectively, compared to 90%, 48%, 81%, 86% for FDG-PET / CT and 98%, 75%, 91%, 94% for PET/MRI fusion. Eight lesions with luminal subtype, one lesion triple negative and one lesion HER2 positive were false-negative FDG-PET/CT. Fused PET/MRI images enabled correct diagnosis of 13 false positive MRI lesions. MRI detected axillary nodal disease in 19 patients, whereas FDG-PET/CT detected axillary nodal disease in 33 patients, internal mammary nodal disease in 3 patients, and unsuspected distant metastases in 6 patients. Conclusions: The fusion of prone MRI and 18F-FDG PET images is a feasible technique. In patients with newly diagnosed breast cancer, MRI had better sensitivity for the primary tumour. PET/MRI fusion increased the sensitivity, specificity, predictive values and accuracy, and could have avoided biopsies in benign lesions. FDG-PET/CT had added value in the detection of unsuspected lymph node and distant metastases.

OP592

Comparison of dedicated hanging breast PET and standard whole body PET/CT for primary tumour visualization in breast cancer patients

S. Teixeira[1], J. Ferrér Rebolleda[2], B. B. Koolen[1], J. Wesseling[1], R. Sánchez Jurado[1], M. P. M. Stokkel[1], M. del Puig Cózar Santiago[2], V. van de Noort[1], E. J. T. Rutgers[1], R. A. Valdés Olmos[1]; [1]Netherlands Cancer Institute - Antoni van Leeuwenhoek Hospital, Amsterdam, NETHERLANDS, [2]ERESA, General university hospital of Valencia, Valencia, SPAIN.

Purpose: Comparison of the performance of a dedicated PET for hanging breast imaging (MAMMI-PET) and whole body PET/CT for the visualization of breast cancer lesions in two European hospitals. Materials and methods: A total of 230 female patients (age: mean 52 y, range 24-82y) with ≥ 1 histologically confirmed primary breast cancer lesion (=index lesion) were included prospectively between March 2011 and March 2014. All patients were scanned with the standard whole body PET/CT (Philips, Eindhoven, Netherlands) followed by the MAMMI-PET (Oncovision, Valencia, Spain) after injection of 180-240 MBq. All index lesions were scored 0, 1 or 2 for quantity of FDG uptake. MAMMI-PET findings were further tested in relation to histological (ductal, lobular) and molecular (ER/PR/Her2) breast cancer subtype, tumour grade, breast length, maximal tumour diameter and affected breast quadrants. Results: Totally 234 affected breasts were scanned (lesion diameter 5-170 mm). Twenty-four lesions (10%) near the pectoral muscle did not reach the MAMMI-PET scanning range. Of 19 lesions that MAMMI missed comparing to PET/CT, 18 were outside its scanning range. For lesions located within its scanning range the MAMMI sensitivity was 98.6%. PET/CT missed 15 of the index lesions depicted by MAMMI (p=0.61). MAMMI-PET detected 41 additional lesions of which 16 where proven malignant (39%), 15 (36.6%) seen on other modalities, and 14 (34,2%) only visible on MAMMI-PET. Lesion visibility was influenced by tumour grade (p=0.034) but not by cancer subtype (p=0.83). Conclusion: When breast cancer is located within its scanning range MAMMI-PET is able to detect almost all

primary tumour lesions. Compared to PET/CT MAMMI-PET finds more cancer lesions provided that these are not too dorsally located in the breast.

OP593

Predictive value of dynamic and dual-phase 18 FDG PET/CT parameters in the assessment of neoadjuvant chemotherapy response in locally advanced breast cancer: A comperative study with dynamic contrast enhanced MRI.

O. Kupik, M. Tuncel, P. Kiratli, M. Akpinar, K. Altundağ, F. Demirkazık, **B. Erbas**; Hacettepe University, Ankara, TURKEY.

AIM: Several studies have shown promising results for the prediction of pathological complete response (pCR) to neoadjuvant chemotherapy (NAC) in patients with locally advanced breast cancer (LABC) using 18 FDG PET/CT. Dynamic contrast enhanced magnetic resonance imaging (dCE-MRI) can assess the response to NAC by providing information on the angiogenesis and morphology of the tumor. This study was planned to compare the predictive value of semi-quantitative paratemers obtained by dCE-MRI, dynamic and dual-phase 18FDG-PET/CT in LABC patients receiving NAC. MATERIALS and METHODS: Fortysix patients with LABC underwent dCE-MRI and 18FDG-FDG/PET at baseline and after 2-3 cycles of NAC (interim). Tumor diameter, spherical (SV), angiographic volumes (AV), peak signal intensity (PSI), rapid and medium component of initial rise, percentage of Type I, Type II, Type III curves were calculated. Dynamic 18FDG and dual phase images were recorded in the prone position. Using 18FDG dynamic data, SUVmax values for 2nd, 5th and 30th minutes were measured. In addition, SUL2peak, metabolik volume (Per2V) and total lesion glycolysis (Per2TLG) values were measured for the first 2 minutes data. For early (E) and late (L) images, SUVmax, SUVmean and SUVpeak, TLG and metabolic tumor volume (MTV) was measured using adaptive (adp) and 42% thresholding method. Baseline and interim studies were used to calculate percentage changes and compared according to the surgery results; pCR vs non-pCR. ROC curves were obtained to calculate the AUCs for the prediction of pCR. Optimal treshold values to discriminate between pCR and non-pCR were calculated. RESULTS: Late prone images had higher sensitivity and specificity to detect the residual tumor (91%, 71.4%) and residual lymph node (62.5%, 87.5%) compared to MRI (84%, 37.5%, LN: 37.5%, 57.5%) and early prone images (84.5%, 75%, LN: 50%, 83%). PET/CT parameters were significantly different between pCR and non-pCR groups, except MTV-42 values. MRI parameters were different for diameter%, SV% and PSI%. Higher AUC values were obtained for SV% (0.83), Per2V% (0.826), MTV (% 0.79), TLG% (0.785), and TTLG % (0.828). Optimal cut-off values (sens, spec.and acc.) values were -65% for SV% (80%, 73%, 75%), -67.6% for Per2V% (87%, 78%, 80.7%), -73% for MTV% (78%, 86%, 84%), -88% for TLG% (78%, 81%, 80%), and -88% for TTLG (78%, 86%, 84%), respectively. CONCLUSION: Semi-quantitavite parameters for 18 FDG PET/CT and volumetric changes obtained with dCE-MRI can predict response to NAC. Percentage changes in MTV, TLG and Per2V can identify nonresponding patients better than other parameters.

OP594

Treatment response evaluation by 18F-FLT positron emission tomography/ computed tomography after neoadjuvant chemotherapy in patients with locally advanced breast cancer

B. R. Mittal, J. Shukla, G. Singh, A. Bal, D. Kumar, M. Kumar, R. Vatsa, P. Bhusari, N. Rana, N. Khandelwal; Postgraduate Institute of Medical Education & Research, CHANDIGARH, INDIA.

OBJECTIVE: Breast cancer is a common cancer in women. 18F-fluorothymidine (FLT) is tracer for proliferation imaging. The aim of this prospective study was to assess the role of 18F-FLT PET/CT in early changes in SUVmax to NACT response and to correlate with final clinical and pathological response to NACT. Methods: 18F-FLT was synthesized and quality control was performed. 44 patients (mean age 47.5±8.54 years) of LABC were enrolled. Patients received 4 cycles of anthracycline based chemotherapy at 3 weeks interval followed by a Taxane based therapy for next 4 cycles at 3 weeks interval. 18FLT PET/CT scans were performed before therapy and was repeated after 1st, 4th and 8th chemotherapy cycles. The receptors (ER, PR, Her2) and Ki-67 expression was studied on biopsy or surgical samples after each PET/CT scan. The SUVmax of 18 patients was calculated. The correlation between 18FLT PET/CT at various time points and post therapy response was studied. Results: Of the 44 patients, only 19 patients completed NACT. Out of 19, 3 were triple negative (ER/PR/Her2), 3 with ER/PR with Her2, rest were ER/PR. The surgery was performed for 17 patients, one patient was not operated due to uncontrolled diabetes and one opted to withdraw. Out of 17 patients, 6 patients showed complete, 6 partial, 2 no response and 3 showed progression of disease on 18FLT PET/CT after end of therapy. No correlation was found with receptor expression. These results were well correlated with pathological assessment. After Ist chemocycle SUVmax in 4 patients increased. Two of the 4 showed complete response, one partial (56%) and one showed disease progression. 18F-FLT PET/CT after completion of Antracyclin therapy (4 cycles) showed complete response in 3 patients, partial in

13 patients and minimal in 2 patients (3%, 7%). However FLT scan done at the completion of Taxane therapy, showed disease progression in 2 patients, decreased response from previous therapy in 4 patients (3% to(-22%); 90 to70%, 40 to30%, 20 to(-40%), improved response in 5 (1-56%, 3-22%, 19-77%, 7-52%, 28-55%), no change was seen in 2 patients, 5 patients showed complete response on PET/CT. 4 out of 5 could be correlated with pathological response. The initial data demonstrate i) there is no correlation between type of receptor expression and outcome of therapy; ii)18F-FLT PET/CT after Ist cycle of chemotherapy does not predict response; iii)18F-FLT PET/CT after 4th cycle plays an important role in assessing the responders and non-responders.

OP595

Prognostic value of maximum standardized uptake value measured on F-18 FDG PET/CT in patients with recurrent epithelial ovarian cancer.

X. Palard; University Hospital of Brest, Brest, FRANCE.

OBJECTIVE: This study aimed to evaluate the prognostic value of maximum standardized uptake value (SUV max) measured on F-18 FDG PET/CT (FDG PET/CT) at the time of relapse in patients with epithelial ovarian cancer (EOC). METHODS: 41 consecutive relapsed EOC patients were retrospectively analysed from April 2006 to April 2014. SUV max was measured on FDG PET/CT at the time of relapse. Post-relapse overall survival (PRS) was calculated from the date of FDG PET/CT to the date of death or last follow-up. ROC analysis was used to test the statistical significance of the differences among patient characteristics. Univariate and multivariate analysis for PRS were performed using Cox proportional hazards regression model. RESULTS: Median follow-up was 20.4 months. 19 patients died during the follow-up period (median: 15.5 months). ROC analysis revealed that SUVmax > 11.7 yielded the best prediction of death (AUC = 0.761). On univariate analysis, SUVmax > 11.7, non serous carcinoma, positive macroscopic residual tumor after initial surgery, time of relapse after initial surgery < 24 months and treatment of recurrence with chemotherapy alone were all significantly associated with PRS. On multivariate analysis, SUVmax > 11.7 (HR, 7.059; 95% CI, 1.620 - 30.764; p=.009), non serous carcinoma (HR, 3.892; 95% CI, 1.377 - 11.003; p=.010) and time of relapse after initial surgery < 24 months (HR, 5.180; 95% CI, 1.280 - 20.964; p=.021) were independently and significantly prognostic factors for PRS. Patients with SUVmax > 11.7 showed significantly longer duration of PRS than patients with SUVmax ≤ 11.7 (Log rank test, χ^2 = 9, p=0.002). CONCLUSION: Our results suggest that SUV max measured on FDG PET/CT at the time of the relapse was found to be an independent predictive value for PRS in patients with recurrent epithelial ovarian cancer.

OP596

Impact of the FDG PET/CT in the primary staging of locally advanced Cervical Squamous Cell Carcinoma (CSCC).

A. Alessi[1], A. Lorenzoni[1], D. Lorusso[2], A. Cerrotta[3], V. Chiappa[2], B. Pappalardi[3], B. Padovano[1], G. Serafini[1], F. Raspagliesi[2], F. Crippa[1]; [1]Nuclear medicine PET Unit Fondazione IRCSS Istituto Nazionale Tumori, Milano, ITALY, [2]Gynecologic Oncology Unit - Fondazione IRCSS Istituto Nazionale Tumori, Milano, ITALY, [3]Radiotherapy Unit - Fondazione IRCSS Istituto Nazionale Tumori, Milano, ITALY.

Locally advanced Cervical Squamous Cell Carcinoma (CSCC) has a higher rate of recurrence and worse survival than early stage CSCC. Predictors of disease recurrence include stage and lymph node status at the time of initial diagnosis. Accurate staging is important both for selecting appropriate therapy and for prognosis. Aim The objective of this retrospective study was to evaluate the impact of FDG PET/CT in the pretreatment imaging work-up of patients with locally advanced CSCC and management change in treatment intend or radiotherapy planning. Materials and methods 35 patients with newly diagnosed locally advanced CSCC (FIGO stage IB2 to IVA) were included in the study. Each patient has been evaluated with pre-therapeutic FDG PET/CT and pelvic MRI. Patients were treated with concomitant chemoradiation and brachytherapy and/or adjuvant chemotherapy or radical surgery depending on staging results. The para-aortic region was included in RT planning in case of FDG PET evidence of disease in para-aortic lymph nodes. FDG PET findings were compared to those obtained with MRI, histopathological results or other imaging modalities in case of extra-pelvic evidence of disease on FDG PET. Results FDG PET-CT and MRI findings were concordant in 69% of patients (24/35 pts). In 20 patients FDG-PET identified only primary tumor with no evidence on lymph node involvement and in 4 patients also hypermetabolic pelvic lymph node were shown, according to MRI. In the remaining 11 patients (31%) FDG PET-CT identified extra-pelvic disease. In 5 out of 11 patients FDG PET-CT revealed retroperitoneal para-aortic (3/5) and mediastinal lymph node involvement (2/5). In 6/11 patients FDG PET-CT detected distant metastatic disease (hepatic, pulmonary, peritoneal and/or bone disease). FDG PET-CT had major clinical impact in 31% of the cases (11/35): in 3 patients with para-aortic node involvement radiotherapy field was extended and in the remaining 8 patients with metastatic disease treatment intend changed to palliative therapy instead of radically

curative. Conclusion Our results showed that FDG PET-CT has an important impact on the primary staging of locally advanced CSCC leading to a substantial changes in treatment planning in 31% of patients.

OP597

Determinants of sentinel node localization failure in gynaecological cancers: a retrospective cohort study.

E. Odouard[1], A. Tescaru[1], F. Giammarile[1], C. Bournaud[1], **S. Lancelot**[1,2]; [1]Hôpitaux de Lyon, Lyon, FRANCE, [2]Lyon Neuroscience Research Center, Université Claude Bernard Lyon 1, INSERM,CNRS, Lyon, FRANCE.

Aim: Sentinel lymph node (SLN) examination is a standard of care for patients with breast cancer and melanoma. The lack of consensus does not permit standardization of the technique in endometrial or cervical cancer. This retrospective study assessed the determinants of SLN detection failure in gynaecological indications.Material and methods:We reviewed all patients who underwent preoperative lymphoscintigraphy and peroperative SLN (Patent Blue injection followed by lymphadenectomy and SLN mapping) localization for early cervical or endometrial cancer in our center (from 2005 to 2015). SLNs were ultra-staged on final pathology.We evaluated the impact of various factors on the SLN localization : the radiopharmaceutical used ([99mTc]rhenium sulfide nanocolloid, Nanocis® or [99mTc]albumin nanocolloid, Nanocoll®), the preoperative imaging modality (planar lymphoscintigraphy or SPECT-CT), and the delay between the radiopharmaceutical injection and the peroperative SLN localization (short in one-day or long in two-day protocol).We defined SLN detection as an examination where at least one sentinel node was identified in both sides.Results: One hundred and nineteen patients with cervical cancer were included. SLNs were detected in both sides in 78 patients (65.5%) in preoperative lymphoscintigraphy, and 80 patients (67.2%) in the operating room. The SLN detection reached 83.5% (66/79) with [99mTc]rhenium sulfide nanocolloid, versus 58.3% (14/24) with [99mTc]albumin nanocolloid (p=0.009).Fifty-seven patients with endometrial cancer were included.SLNs were detected in both sides in 25 patients (44%) in preoperative lymphoscintigraphy, and 27 patients (54%) in the operating room. The SLN detection reached 57.5% (23/40) with [99mTc]rhenium sulfide nanocolloid, versus 37.5% (3/8) with [99mTc]albumin nanocolloid (not significant).For both indications, no significant differences were observed between one-day-protocol and two-day-protocol for SLN detection. The SLN detection was higher with SPECT-CT imaging compared to planar lymphoscintigraphy (not significant).Conclusion:To our knowledge, this is the first time that the role of the radiopharmaceutical and the delay of the procedure were studied. This study revealed that the radiopharmaceutical choice could be a factor influencing the success of SLN localization in cervical cancer. The SLN procedure should be performed with the [99mTc]rhenium sulfide nanocolloid in the cervical cancer.As described in the literature, preoperative SLN imaging with SPECT-CT should result in a superior overall SLN detection when compared to planar lymphoscintigraphy. These results must be confirmed by further studies.

Diagnostic and prognostic value of 18F-DOPA PET and 1H-MR Spectroscopy in pediatric supratentorial infiltrative gliomas: a comparative study.

M. Massollo[1], **A. Piccardo**[1], G. Morana[2], M. Puntoni[3], C. Milanaccio[4], M. Garrè[4], A. Rossi[2], M. Cabria[1], A. Raso[5], I. Bossert[1], M. Cabria[1]; [1]Nuclear Medicine Unit E.O. Galliera Hospital, Genoa, ITALY, [2]Neuroradiology Unit, Istituto G. Gaslini, Genova, Italy, Genoa, ITALY, [3]Clinican Trial Unit, Scientific Directorate, Ospedali Galliera, Genova, Genoa, ITALY, [4]Neuro-oncology Unit, Istituto G. Gaslini, Genova, Italy, Genoa, ITALY, [5]Neurosurgery Unit, Istituto G. Gaslini, Genova, Italy, Genoa, ITALY.

AIM: 1H-MR Spectroscopy (MRS) and 18F-dihydroxyphenylalanine (DOPA) PET are noninvasive imaging techniques able to assess metabolic features of brain tumors. The aim of this study was to analyze metabolic information obtained by 18F-DOPA PET and 1H-MRS in a population of children with supratentorial infiltrative gliomas or non-neoplastic brain lesions initially suspected to be gliomas on conventional MRI. Specifically, we aimed (1) to compare sensitivity, specificity and accuracy of 1H-MRS and 18F-DOPA PET in distinguishing brain gliomas from non-neoplastic lesions, (2) to assess the ability of 1H-MRS and 18F-DOPA PET in discriminating low-grade from high-grade gliomas, and (3) to evaluate the relationship between these different metabolic biomarkers and patient's outcome in terms of progression-free survival (PFS) and overall survival (OS). MATERIALS AND METHODS: We retrospectively analyzed 27 pediatric patients with supratentorial infiltrative brain lesions on conventional MRI (21 gliomas and 6 non-neoplastic lesions) who underwent 18F-DOPA PET and 1H-MRS within 2 weeks of each other. 1H-MRS data (Choline/Nacetylaspartate, Choline/Creatine ratios, and presence of lactate) and 18F-DOPA uptake parameters (Lesion/Normal tissue and Lesion/Striatum ratios) were compared and correlated

with histology, WHO tumor grade, and patient's outcome. RESULTS: 1H-MRS and 18F-DOPA PET data were positively correlated. Sensitivity, specificity, and accuracy in distinguishing gliomas from non-neoplastic lesions were 95%, 83%, and 93% for 1H-MRS and 76%, 83%, and 78% for 18F-DOPA PET, respectively. No statistically significant differences were found between the two techniques ($p>0.05$). Significant differences regarding 18F-DOPA uptake and 1H-MRS ratios were found between low- and high-grade gliomas ($p\leq0.001$ and $p\leq0.04$, respectively). On multivariate analysis, 18F-DOPA uptake independently correlated with progression free survival ($p\leq0.05$) and overall survival ($p=0.04$), whereas 1H-MRS did not show significant association with outcome. CONCLUSION: 1H-MRS and 18F-DOPA PET provide useful complementary information for evaluating pediatric brain lesion metabolism. In view of its better availability, lower costs, and lack of radiation exposure, 1H-MRS represents the method of first choice in differentiating brain gliomas from non-neoplastic lesions. 18F-DOPA uptake better discriminates between low- and high-grade gliomas, and is an independent predictor of PFS and OS.

OP599

[18F]-fluciclovine (FACBC) PET/CT as a Supplement to MRI in Patients with Suspected Recurrent Gliomas

A. Londalen, T. Bach-Gansmo, C. Saxhaug, P. Brandal, T. V. Bogsrud; Oslo University Hospital, Oslo, NORWAY.

Aim: Early detection of recurrence or residual disease after treatment of gliomas with advanced oncological imaging techniques can positively influence the course of disease and overall survival. Post-therapeutic tissue changes which mimics tumor recurrence (pseudoprogression) and radiation necrosis are common problems. MRI has limited ability to differentiate pseudoprogression and radiation necrosis from tumor recurrence. Preliminary clinical studies demonstrated high tumor specific accumulation of the synthetic leucine analog, trans-1-amino-3-[18F]fluoro-cyclobutyl-carboxylic acid (fluciclovine, often called FACBC) in small numbers of glioblastomas. The aim of this study is to evaluate fluciclovine PET/CT as a supplement to MRI to help differentiate tumor recurrence from pseudoprogression and/or radiation necrosis. Methods: Ten consecutive patients previously treated for gliomas with suspected tumor recurrence were included in this study (4 females and 6 males) with a median age of 55 years (range 41-63 years). All patients signed a written informed consent form. Tumor diagnoses consisted of grade II in three, grade III in one and grade IV gliomas in six patients initially. The patients first underwent MRI (structural and functional imaging sequences), which were performed as part of the clinical routine; and then they underwent fluciclovine PET/CT because of suspected tumor recurrence or pseudoprogression/radiation necrosis. Tumor to background ratios (TBR) were calculated. Eight of these patients went through surgery because of suspected tumor recurrence and histological results were obtained. Results: In eight of the ten patients who underwent surgery, recurrent glioma was confirmed by histopathology. Fluciclovine PET/CT had high tracer uptake in all 8 patients preoperatively (TBRs 4,7-45 median 14,3). MRI was not conclusive in four of them and suspected tumor recurrences were noted in the other four. Two patients were followed-up. MRI showed possibly radiation necrosis in one (TBR 14,2 on PET/CT) and possible recurrence in the other (TBR=2.8 on PET/CT). Both showed clinical signs of progression, and they died 40 days and 6 months after the fluciclovine PET/CT, respectively. Conclusion: In our study fluciclovine PET/CT showed high TBRs in histopathologically confirmed tumor recurrences of gliomas. Our results indicate that fluciclovine PET/CT might be used as a supplement to MRI to differentiate tumor recurrence from treatment induced changes.

OP600

PET/MR versus PET/CT in the Initial Staging of Head and Neck Cancer

T. Sekine[1,2], F. Barbosa[1], F. Kuhn[1], I. Burger[1], G. von Schulthess[1], P. Veit-Haibach[1], M. Huellner[1]; [1]University Hospital Zurich, Zurich, SWITZERLAND, [2]Nippon Medical School, Tokyo, JAPAN.

Purpose: To compare the diagnostic accuracy of PET/MR with PET/CT for newly diagnosed head and neck cancer. Materials and Methods: This prospective study was approved by the institutional review board and by national government authorities. In this study, sequential contrast-enhanced PET/CT-MR was performed in 27 patients (median age 66, 16 males) with newly diagnosed head and neck cancer. MR sequences were: LAVA-Flex (whole body); axial T2-weighted, axial T1-weighted with and without contrast, sagittal and coronal T1-weighted with contrast, and DWI (head and neck). PET/CT and PET/MR were evaluated separately, and the TNM stage and factors that could impact on the potential resectability were assessed. Wilcoxon signed-ranks test was used. Results: The T/N/M staging by PET/CT was correct in 17 patients (63.0%) / 19 (70.4%) / 22 (81.5%), equivocal in 8 patient (29.6%) / 3 (11.1%) / 3 (11.1%), and incorrect in 2 patients (7.4%) / 5 (18.5%) / 2 (7.4%). The T/N/M staging by PET/MR was correct in 20 patients (74.1%) / 21 (77.8%) / 26 (96.3%), equivocal in 6 patients (22.2%) / 2 (7.4%) / 1 (3.7%), and incorrect in 1 patient (3.7%) / 4 (14.8%) / 0 (0%). Consistently, the TNM staging by PET/MR was comparable to PET/CT (T: $p = 0.331$, N: $p = 0.453$, M: $p = 0.034$). The sensitivity/specificity/accuracy of resectability-defining factors by PET/CT

and PET/MR were 0.68/0.93/0.97, and 0.80/1.00/0.99, respectively. Conclusion: Whole-body staging with PET/MR yields at least equal diagnostic accuracy as PET/CT in determining the stage of head and neck cancer.

OP601

11C-methionine PET-CT for contouring and response evaluation of Head and Neck Adenocystic Carcinoma treated with CIRT (Carbon Ion Radiation Therapy)

L. Olivari[1], M. Bonora[2], M. Rodari[3], M. Fiore[2], V. Vitolo[2], E. Lopci[3], F. Valvo[2], P. Fossati[2], R. Orecchia[1], A. Chiti[4]; [1]University of Milan, Milano, ITALY, [2]Division of Radiation Oncology and Radiobiology, National Center for Oncological Adrontherapy (CNAO) Foundation, Pavia, ITALY, [3]Department of Nuclear Medicine, Humanitas Research Hospital, Milano, ITALY, [4]Humanitas University, Milano, ITALY.

INTRODUCTION: Adenocystic carcinoma (ACC) is a rare radio resistant head and neck cancer that usually locates close to critical structures. CIRT, which shows some advantages to treat radio resistant tumours, needs precise target definition. Previous studies reported that 11C-methionine PET-CT (MET) could be an effective alternative to FDG, due to its low uptake in normal brain and in inflammatory tissue. METHODS: In this prospective study, 47 patients affected by ACC and treated with CIRT were investigated with MET. Pre-treatment MET, registered and fused with simulation CT, was employed as a visual aid in target contouring. MR images (T2 weighted, T1 weighted and contrast enhanced T1 weighted) were also used. Volumes with MET uptake comparable with parotid glands were included in the Clinical Target Volume (CTV); asymmetric findings with an uptake value between parotid and brain were also included, but treated with a lower dose. Pre-treatment MET failed to show abnormal uptake in 7 patients (15%). In patients with elevated initial uptake, a post treatment MET was performed one month after completion of CIRT. Semi-quantitative tumour to normal brain ratio (T/B) and volumetric change in MET uptake were evaluated in both MET exams. Dimensional response was investigated with MR every 3 months since the end of CIRT.The minimal follow up period was 5 months (range 5-22). RESULTS: Forty patients with ACC performed pre and post treatment MET. Sixteen patients had previous history of ACC (recurrent disease) while 26 had a newly diagnosed ACC. Twenty-three patient underwent surgery before CIRT. CIRT was well tolerated and none of the patient had G3-G4 toxicity three months after treatment. T/B ratio showed a mean reduction of 55% (range -100% to + 14.6%) and MET volumetric change showed a mean reduction of 72.9% (range -100% to +172%). Fifteen patients had MET complete response after CIRT, confirmed at follow-up. MET after CIRT detected progressive disease in 9/10 patients. One patient had a negative MET while MR was inconclusive. Disease was detectable six months after the end of CIRT. Fifteen patients had partial response on both MET and MR, with stable disease at follow-up. CONCLUSIONS: When used together with MR, MET demonstrated to be useful in target delineation and early response evaluation of patients affected by ACC treated with CIRT. T/B ratio and tumour volumetric changes assessed with MET, are able to increase the diagnostic accuracy of the pure qualitative image evaluation.

OP602

Value of FDG volumetric imaging parameters before radiotherapy treatment in inoperable Head and Neck cancer (HNC)

L. Olivari[1], E. Lopci[2], A. Poletti[3], R. Cavina[4], C. Arturo[5]; [1]University of Milan, Milano, ITALY, [2]Department of Nuclear Medicine, Humanitas Research Hospital, Milano, ITALY, [3]Department of Otorhinolaryngology, Humanitas Research Hospital, Milano, ITALY, [4]Department of Oncology, Humanitas Research Hospital, Milano, ITALY, [5]Humanitas University, Rozzano, Milano, ITALY.

INTRODUCTION: Inoperable head and neck cancer (HNC) are treated with concurrent chemo-radiotherapy (CCRT) alone or associated with induction chemotherapy: docetaxel, cisplatin, 5-fluorouracil (DCF). The aim of this study was to evaluate whether metabolic tumour volume (MTV) and total lesion glycolysis (TLG) of the primary tumour and nodes before CCRT and DCF-CCRT can predict outcome for patients with inoperable HNC.METHODS AND MATERIALS: Sixty-three consecutive patients with biopsy-proven, newly diagnosed, non operable HNC were included in this retrospective study. None of these patients had history of radiation therapy in head and neck district. All patients underwent FDG PET-CT before radiotherapy. An automatic algorithm, based on adaptive thresholding, delineated primary tumour and nodes. With this technique we calculated: MTV, TLG, SUVmax, SUVmean. The primary endpoint was

progression free survival (PFS). Univariate Cox regression models and Kaplan Meir with respect to PFS were performed.RESULTS: The cohort consisted of 19 female, 44 male; mean age 62,2±12.8 years. The distribution of patients by the AJCC stage of the cancers included stages I (n=3), II (n=9), III (n=15), IVa (n=34), IVb (n=1) IVc (n=1). Histology was: squamous cell carcinoma (n=49), undifferentiated carcinoma (n=12), adenocarcinoma (n=2). Tumour localization was: rhinopharynx (n=19) oropharynx (n=28), hypopharynx (n=8) and larynx (n=8). The mean follow-up was 23 months (range, 5-52 months). Six patients performed follow up in other centres. Two patients died during follow up of unrelated cancer disease. Progressive disease (PD) was demonstrated in 13 patients after a mean interval of 12.7 months (range, 7-33 months). PD occurred mainly in advanced cancer (stage IV at the diagnosis: n=8) and the primary tumour localization was mainly rhinopharynx (n=7). Cox regression demonstrated that MTV of the primary tumour value is a significant predictor with respect to PFS ($p<0.05$). Kaplan Meier analysis showed that MTV of the primary tumour less than 4.3 indicates good median PFS ($p<0.05$) with a sensitivity and specificity of 82% and 70% respectively. No correlation was found between PFS and MTV of lymph nodes. No correlation was found between PFS and SUVmax, SUVmean and TLG of the primary tumour and of the lymph nodes.CONCLUSION: In this patient population, MTV provided information of disease burden and tumour metabolic activity. High baseline primary tumour MTV (pre CCRT) was associated with worst outcomes in patients with inoperable HNC. Pre-radiotherapy MTV of primary tumours provides independent prognostic information and the threshold of 4.3 seems to predict PFS in inoperable HNC.

OP603

Predictive role of FDG-PET/CT in patients with locally advanced oropharyngeal cancer undergoing tomotherapy with dose escalation

E. Incerti[1], I. Dell'Oca[2], M. Kirienko[3], C. Fiorino[4], P. Alongi[3], S. Broggi[4], P. Mapelli[1], N. Di Muzio[2], L. Gianolli[1], M. Picchio[1]; [1]Nuclear Medicine Department, IRCCS San Raffaele Scientific Institute, Milan, ITALY, [2]Radiotherapy Department, IRCCS San Raffaele Scientific Institute, Milan, ITALY, [3]University of Milano-Bicocca, Milan, ITALY, [4]Medical Physics Department, IRCCS San Raffaele Scientific Institute, Milan, ITALY.

Aim: To evaluate the clinical outcome in patients affected by locally advanced oropharyngeal cancer undergoing intensity modulated radiation therapy, by means of helical tomotherapy (HTT), with dose escalation to FDG-PET/CT positive tumor volumes using the simultaneous integrated boost (SIB). Materials and Methods: We analyzed 38 patients studied by FDG-PET/CT and treated between 2005 and 2013 for squamocellular oropharyngeal stage III-IVB disease in our Institution. HTT was delivered with the SIB technique (HTT-SIB) in 30 fractions at different dose levels concomitantly: 69 Gy (2.3 Gy/day) to the gross tumor volume PET-positive (GTV-PET) for lymph nodes (LN) and primary tumor (T), 66 Gy (2.2 Gy/day) to the clinical target volume (CTV) for LN and T, 54 Gy (1.8 Gy/day) to the clinical negative neck region. Thirty-one patients received concurrent chemotherapy (cisplatin 75-100 mg/m^2/21 days for 23 patients, cisplatin 30-40 mg/m^2/week for 6 patients and cetuximab for 2 patients). The 2.5-year overall cancer specific (OS), local tumor disease-free (LTDFS), local node disease-free (LNDFS) and distant metastasis-free (DMFS) survivals were calculated. Correlations between PET volumetric parameters and 2.5-year OS, LTDFS, LNDFS and DMFS were assessed. The PET/CT metabolic parameters of T include GTV-T-PET, metabolic tumor volume (MTV-T), MTV thresholds 40%-50%-60% (MTV-T-40, MTV-T-50, MTV-T-60) and mean standardized uptake value (SUVmean). Results: The median follow-up was 28 months (range: 3-109 months). All patients completed the treatment as scheduled. The 2.5-year OS, LTDFS, LNDFS and DMFS were 88%, 83%, 88% and 77%, respectively. Multivariate Cox regression analyses revealed that GTV-PET and GTV-T-PET are predictors for OS with a best-cut-off value equal to 30.9 cc ($p=0.022$) and 22.4 cc ($p=0.029$) respectively; while MTV-T-40, MTV-T-60 and SUVmean are predictors for OS with a best-cut-off value equal to 21.3 ($p<0.0001$), 13.3 ($p<0.0001$) and 9.2 ($p=0.01$), respectively. Temporary treatment interruption due to acute toxicity, mainly mucosae, was observed in 8 patients. Conclusions: The use of HTT-SIB with dose escalation to FDG-PET/CT positive tumor volumes, even with concurrent chemotherapy, allows very promising 2.5-year disease control rates in patients affected by locally advanced squamocellular oropharyngeal cancer. Moreover PET/CT metabolic volumetric parameters have a predictive value for the survival outcomes, thus FDG-PET/CT may represent the basis for more personalized treatments.

OP604

Diagnostic accuracy of F18-FDG-PET/CT for the detection of perineural spread in head and neck cancer

L. Dercle, S. Ammari, L. Rozenblum, D. Deandreis, M. Terroir, M. Schlumberger, F. Bidault; GUSTAVE ROUSSY, Villejuif, FRANCE.

Background: Head and neck cancer (HNC) spread locoregionally by direct extension, lymphatic dissemination, and neurovascular spread. The accuracy of FDG-PET/CT for the diagnosis of perineural spread (PNS) remains to be determined because it could improve risk stratification, staging, treatment planning, and follow-up. Two limiting factors exist: the limited resolution of PET (partial volume effect) and the physiological FDG-uptake of the nearby brain. This report evaluates the accuracy of FDG-PET/CT and describes clinical, morphological (CT-scan), and metabolic patterns (18F-FDG-PET) attributed to neoplastic involvement along the cranial nerves (CN).Methods: Twenty-five patients were retrospectively included. MRI was used as the reference-standard. Thirty-two PNS were diagnosed. PNS was proved histologically (surgery) or suspected according to a typical evolution on long term follow-up (443±492 days). Quantitative results are expressed as mean ± SD.Results: The sensitivity of FDG-PET/CT for the detection of PNS was 88%. Two false negatives were noted and explained by a low FDG-uptake of the primary tumor due to 1/ the histological subtype, 2/ an excellent response to radiochemotherapy.They are 5 morphological and metabolic patterns observed in PNS: 1/ A typical topography of the lesion along CN: CNV1 (8%), CNV2 (50%), CNV3 (54%), and CNVII (8%). 2/ A significant enlargement along the CN (PNS: 9±5 mm, doubling size of the nerve: Se84%, ratio $CN_{abnormal/normal}$: 4.3±3.1 which is above PET-resolution and is measurable on CT-scan). 3/ An asymmetrical increased FDG-uptake (Se88%; significantly different from the physiological brain uptake; $SUVmax_{PNS:}$ 20±11; $SUVmax_{brain:}$ 17±5). 4/ An Heterogeneity Index of the SUV of the CN similar to the tumor and significantly increased in comparison with the physiological brain uptake ($HISUV_{tumor:}$ 1.5±0.2, $HISUV_{PNS:}$ 1.5±0.1, $HISUV_{brain:}$ 1.2±0.1, $HISUV_{PNS/primary:}$ 1.0±0.1, $HISUV_{PNS/brain:}$ 1.3±0.1); 5/ An enlargement of the foramina in the base of skull (doubling size of the foramen: Se64%, ratio $foramen_{abnormal/normal}$: 2.6±1.6).Conclusions: FDG-PET/CT is accurate for the detection of PNS. The diagnostic accuracy of five direct and indirect signs of PNS on FDG-PET/CT was described.

OP605

Head and neck cancer: can 18F-FDG PET/CT staging scan improve the predictive value of post-treatment 18F-FDG PET/CT assesment

I. Sandler[1], G. M. Lima[1], P. Castellucci[1], U. Caliceti[2], S. Cammelli[3], V. Allegri[1], A. Morganti[3], S. Fanti[1]; [1]Università di Bologna, Nuclear Medicine Unit, S.Orsola-Malpighi Hospital, Bologna, ITALY, [2]Università di Bologna, Head and Neck Unit , S. Orsola-Malpighi Hospital, Bologna, ITALY, [3]Università di Bologna, Radiotherapy Unit, S. Orsola-Malpighi Hospital, Bologna, ITALY.

Aims: The purpose of this retrospective study is to evaluate whether a staging or pre-treatment 18F-FDG PET/CT scan may improve the predictive value of 18F-FDG PET/CT in treatment response assessment after primary radio-chemotherapy (RT-CT) for loco-regional advanced Head and Neck squamous cell carcinoma (HNSCC). Methods: We enrolled 138 patients with a diagnosis of advanced HNSCC (96 males and 42 females, mean age 58 yo) who performed a 18F-FDG PET/CT between 2006-2013. Disease sites were oral cavity (10%), nasopharynx (14%), oropharynx (53%), hypopharynx (7%), larynx (7%), salivary glands (5%) and paranasal sinuses (4%). All patients have been treated with primary RT-CT. All patients underwent a 18F-FDG PET/CT to assess treatment response, preformed from 6 to 36 weeks (60% between 10-15 weeks) after the end of RT-CT. In 84 patients (60%) a 18F-FDG PET/CT staging or pre-treatment scan have been also performed (group A) while for the remaining 54 patients (40%) a staging 18F-FDG PET/CT was not available (group B). There were no significant differences in terms of risk stratifications between the two groups. 18F-FDG PET/CT scans were performed according to standard procedure and were visually analyzed by two expert physicians and categorized as negative or positive for residual disease. Patients were followed-up, based on clinic and radiological and/or histological findings, up to 60 months and for at least 12 months after end of therapy (median 38 months). At the end of follow-up, 18F-FDG PET/CT results were classified as true positive (TP), true negative (TN), false positive (FP) and false negative (FN). Results: - Group A (84 patients) showed: 30 TP (36%), 46 TN (54%), 3 FP (4%) and 5 FN (6%). Therefore 18F-FDG PET/CT sensitivity 86%, specificity 94%, PPV 91%, NPV 90%, accuracy 0.9. - Group B (54 patients) showed: 11 TP (20%), 38 TN (70%), 1 FP (3%) and 4 FN (7%). Therefore 18F-FDG PET/CT sensitivity 73%, specificity 97%, PPV 91%, NPV 90%, accuracy 0.9. Conclusions: According to our data, 18F-FDG PET/CT scan in staging of HNSCC does not improve significantly the Positive and Negative predictive values of post-treatment PET/CT. These results should be confirmed by larger studies.

3D patient absorbed dose estimation of monoclonal antibody targeting synovial sarcoma

D. Sarrut, J. Badel, A. Halty, D. Kryza, A. Giraudet; CREATIS / LUMEN, Lyon, FRANCE.

Aims: Frizzled homologue 10 (FZD10) is transmembrane receptor overexpressed in synovial sarcoma (SS). We investigated the patient absorbed dose distribution of OTSA101-DTPA-90Yttrium, a radiolabeled monoclonal antibody (mAb) targeting FZD10 developed by Oncology Therapy Science, in relapsing metastatic SS patients included in a first-in-man phase I clinical trial based on a theranostic procedure.Materials and Method: Biodistribution was analysed in 20 patients on SPECT-CT acquisitions repeated at 1, 5, 24, 48, 72 and 144 h post-injection of 185 MBq/1.5 mg OTSA101-111Indium. In case of significant tumors uptake, greater than mediastinum, and favourable biodistribution, patient was treated with OTSA101-90Y. Retrospectively, volume of interest (VOI) were drawn on H1 CT in various lesions, mainly lung metastases, and normal tissues (liver, kidneys, heart, bone marrow, spleen). Deformable image registration was performed between all CT time-points and used to warp all SPECT time-points onto the same coordinate system allowing pixel-by-pixel time-activity-curves (TAC) analysis. Time-integrated activities were computed from mono-exponential fit of TAC in all pixels and used to compute the 3D estimated absorbed doses of OTSA101-90Y with Monte-Carlo simulation (GATE) at a pixel level.Results: Tumor tracer uptake appeared to be highly heterogeneous on an inter-patient, as well as an intra-patient and inter-lesions based analysis independently of tumor size. Estimated doses to the 95 lesions ranged from [0.01;0.82] cGy by injected MBq (median 0.22). Uptake intensity was considered to be greater than mediastinum in half of the patients, observed as soon as H1 for 2 patients or only at H144 for 2. There was a trend for mAb accumulation in the tumors signing specific mAb tumor uptake. Time-integrated activities appeared to be the highest in the liver with a total estimated dose ranging from [0.34;1.19] cGy/MBq (median: 0.78) ; bone marrow and kidney estimated dose ranged from [0.02;0.19] and [0.06;0.32] cGy/MBq. Conclusion: We confirm FZD-10 antigen expression in SS metastases. OTSA101 lesions uptake is heterogeneous and appeared sufficient for radionuclide therapy for half of the patients. However, estimated dose could not reflect real received dose because of potential difference between OTSA101-111In and OTSA101-90Y. A comprehensive patient-specific absorbed dose estimation combining SPECT-CT acquisitions at several time-points, deformable registration and pixel-based 3D Monte-Carlo computation has been proposed and applied in clinical context.

OP610

Implementation and validation of a collapsed cone superposition algorithm for radiopharmaceutical dosimetry of radionuclides with photon component

M. Sanchez-Garcia[1], I. Gardin[2], R. Lebtahi[1], A. Dieudonné[1]; [1]Department of Nuclear Medicine, Beaujon Hospital, Assistance Publique-Hôpitaux de Paris (APHP) & INSERM U1149, Clichy, FRANCE, [2]Department of Nuclear Medicine, Henri Becquerel Cancer Center and Rouen University Hospital, & QuantIF – LITIS [EA 4108], Rouen, FRANCE.

Objectives: A collapsed cone (CC) superposition algorithm (CCS) has been recently implemented for radiopharmaceutical absorbed dose (AD) calculation of beta emitters (Sanchez-Garcia et al. Phys Med Biol 2014). This paper presents the implementation for radionuclides with a photon component. Methods: The superposition relies on a water dose kernel (DKw) that is linearly scaled by radiological distance between source and target voxels, taking into account tissue density heterogeneities. CC provides an acceleration of the superposition by approximating the energy transport to a finite number of directions. Our CCS implementation was extended to photons and validated on 2 radionuclides used in diagnostic nuclear medicine, F-18 and Tc-99m, and another 2 used in

therapy, I-131 and Lu-177. The DKws were generated for each radionuclide with MCNP Monte Carlo simulations (MC). The validation was done against MCNP in 6 phantoms constituted of 2 concentric (radii of 4 and 8 cm) spheres representing tissue interfaces between soft-tissue, lung and bone. The absorbed dose was scored in concentric shells of 1 mm thickness for CCS and MC, leading to a plot of AD according to the radial coordinate. The metrics used for comparison were the percentage of points in the plot satisfying the γ(3%, 3 mm) and γ(5%, 5 mm) criterions, i.e. the percentage of points satisfying a tolerance of 3% (or 5%) in dose or 3 mm (or 5 mm) in distance to agreement. Results: For F-18, γ(3%, 3 mm) was 100% for all phantoms. For Tc-99m, γ(3%, 3 mm) was between 71 and 97%, except for the bone/lung interface (7%), and γ(5%, 5 mm) was over 99% except for the bone/lung phantom too (57%). For I-131, γ(3%, 3 mm) was between 99 and 100%, except for the bone/lung phantom (92%), but γ(5%, 5 mm) was 100% for all phantoms. For Lu-177, γ(3%, 3 mm) was between 89 and 100%, except again for bone/lung phantom (59%), but γ(5%, 5 mm) was over 97% for all phantoms. Calculation times were between 3.5 and 4 minutes on a 3.2 GHz Intel Core i5 machine with 4 cores. Conclusion: Our results show that the CC superposition algorithm has a good agreement with MC simulations for various tissue interfaces and common radionuclides. This study confirms that CC superposition is a reliable alternative to MC simulations in radiopharmaceutical dosimetry.

OP611

Targeted photodynamic therapy of insulinomas and congenital hyperinsulinism by Exendin-700DX

S. Ekim[1], D. Bos[1], F. Andreae[2], M. Brom[1], M. Gotthardt[1]; [1]Radboud University Medical Centre, Nijmegen, NETHERLANDS, [2]PICHEM, Graz, AUSTRIA.

Background and aims: lnsulinomas are tumors of the pancreas that are derived from beta cells. Because the tumor produces excess amounts of insulin, it can lead to hypoglycemia. Congenital hyperinsulinism is a disease that causes high levels of insulin and hypoglicemia. Exendin is a peptide which can specifically bind to the glucagon-like peptide 1 receptor (GLP-1R) which is expressed in the beta cells in the pancreas. 700DX can create free radicals and singlet oxygen that can be fatal to the cells, when it is subjected to laser irradiation. Labeling Exendin with 700DX can be a promising way to produce a new agent for laser induced photodynamic therapy (PDT) of insulinomas and congenital hyperinsulinism, aimed at selective destruction of diseased beta cells. With this therapy, it would be possible destroy diseased beta cells in a specific area of pancreas and leave a sufficient amount of beta cells to prevent diabetes. Materials and methods: Exendin-3 (Ex-3) and Exendin-700DX (Ex-700DX) were used in the experiments. The therapeutic effect was examined on islets isolated from C3H mice, rat insulinoma cells (lNS-1E) and GLP-1R expressing CHL cells. ln vitro PDT experiments, were performed by incubating islets with 165 nM Ex-700DX, 165 nM Ex-3 and medium only (control) for 3 hours at 37°C. The islets were irradiated for 30 min at 60 Watt, with a LED laser system that emits radiation in the 690nm spectral band while the control plate was not irradiated.An hour after the PDT, cell titer glo assay was performed to detect the islet death. The effect of internalization of Ex-700DX was examined using CHL-GLP1R(+) cells by incubation at 0°C (no internalization) or 37°C (internalization). Results:Nearly 60% islet death was detected after PDT, on the Ex-700DX treated group of islets. No islet death was observed with Ex-3 and vehicle incubated groups after PDT, which proves that the compound and laser irradiation itself does not cause any islet death. The percentage of cell death after PDT was calculated as 44% when Ex-700DX internalized into the cells, while 21% cell death was observed when Ex-700DX was only bound to GLP-1R on the cells. Conclusion:First trials on mice islets and GLP-1R(+) tumor cells showed that PDT with Ex-700DX efficiently destroys the target cells. For efficient PDT, Ex-700DX should be at least bound to GLP-1R and the efficiency of the therapy increases nearly 2 times when Ex-700DX is internalized into the cells.

OP612

Integration of micro- and macro-dosimetry for calculation of radiation doses to the islets of Langerhans due to radionuclide imaging with exendin

I. van der Kroon[1], W. Woliner-van der Weg[1], M. Brom[1], L. Joosten[1], C. Frielink[1], M. W. Konijnenberg[2], E. P. Visser[1], M. Gotthardt[1]; [1]Radboud University Medical Center, Nijmegen, NETHERLANDS, [2]Erasmus Medical Center, Rotterdam, NETHERLANDS.

Aim: Radiolabeled exendin, targeting the GLP-1 receptor, is used for quantification of the insulin producing beta cells located in the islets of Langerhans. High accumulation of the radiolabeled exendin in the islets has lead to concerns about radiation-induced damage to the islets. Standard methods or models to estimate the radiation-induced damage to the islets are not yet available. Commonly used macro-dosimetry methods, such as OLINDA/EXM, do not contain the islets as a separate compartment, therefore these models are not able to provide the radiation dose to single islets. Because of the high accumulation of radiolabeled exendin in islets compared to surrounding tissue, islets need to be included as a separate compartment. In our work, a model was developed to calculate

the islet radiation dose due to the use of ^{111}In-exendin (150 MBq) and ^{68}Ga-exendin (75 MBq) in patients with differences in gender, islet size, beta cell mass and kidney uptake. Materials and Methods: The model includes the radiation dose to the islets due to accumulation of the radiotracer (i) in the kidneys, (ii) in surrounding islets and exocrine tissue in the pancreas (together: remainder of the pancreas) and (iii) in the islet (islet self-dose). The contribution of the remainder of the pancreas and the kidneys to the islet radiation dose was calculated using the standard S-value based approach as implemented in OLINDA/EXM. For the islet self-dose, Monte Carlo simulations were performed for a small sphere model (diameter 50-400 μm). As input for the model both data from a clinical study (organ distribution of the tracer) and data from a preclinical study with biobreeding diabetes prone rats (endocrine-exocrine uptake ratio), was used. Results: The islet radiation dose was found to be small ranging from 49.3 to 74.3 mGy for ^{111}In-exendin and ranging from 1.61 to 2.35 mGy for ^{68}Ga-exendin. The activity in the islets contributed up to 45% to the total islet radiation dose for ^{111}In-exendin and up to 22% for ^{68}Ga-exendin. Due to the high accumulation of radiolabeled exendin in the kidneys, the kidneys have the largest contribution to the total islet radiation dose (49-81%). Conclusion: The calculated islet radiation doses suggest that even repeated exendin imaging will not harm the islets since the maximum islet radiation dose is much smaller than the one known to cause serious islet damage (10 Gy as observed with external beam radiation).

OP613

The intrinsic absorbed dose resolution concept in voxel dosimetry - Application to 90Y microsphere radioembolization

C. Chiesa, M. Mira, M. Maccauro, E. Seregni, F. Crippa; Nuclear Medicine, Foundation IRCCS Istituto Nazionale Tumori, Milan, ITALY.

Aim & background: In radioembolization dosimetry, the analysis of uncertainties is simple, since a single acquisition of a tomographic image is sufficient. Under the local deposition hypothesis, voxel absorbed dose is simply proportional to voxel counts. Image noise (σ/N) was investigated, since it is numerically the level of uncertainty on voxel absorbed dose (intrinsic absorbed dose resolution).Methods: In uniformly filled phantoms, absorbed dose in voxels should be uniform, i.e. the DDVH should be Dirac's delta. The statistical voxel fluctuation should follow a Poissonian dependence on N , $\sigma=\sqrt{N}$. The dependence of noise on the number of iterations #IT and the number of subsets #SUBS was studied on a high statistic (N=8100) 99mTc 20 cm diameter uniform cylinder (several CT attenuation corrected OS-EM SPECT reconstruction (Siemens e.soft work station) without additional postfilter). A 2000 mL plastic bottle simulating liver, filled with a typical liver concentration of 99mTc-MAA (150 MBq/1000 mL), surrounded by non radioactive water, was acquired with clinical scan duration (15 s/projection, 900 s). Its noise was studied by varying the number of updates P=#ITx#SUBS.A TOF LYSO PET scanner was used to study an 90Y bottle in air filled with 90Y-DOTATOC solution with a concentration corresponding to a 40 Gy mean dose, with scan duration of 15 min and 60 min.Results: In 99mTc SPECT, noise was dependent on the number of updates P, and independent on different combinations giving the same P. The larger contribution to noise came from reconstruction. Fixed N=2500 in the bottle simulating liver, the evaluation showed a gaussian shaped DDVH whose width (dose uncertainty) was dependent on the square root of P (R2=0.99), with remarkable voxel dose uncertainty of 5.5%, 9%, 37% for P= 4x4, 8x8, 30x30. After optimization of reconstruction (fixed P=8x8 Chiesa et al 2015), such uncertainty could be slightly reduced increasing N (higher activity or longer acquisition time). In the 90Y PET (blob reconstruction, 3 IT, 28 subsets) reconstruction and Poisson noise were comparable. The poor N=16 cannot be improved (using LYSO), since the therapeutic activity is fixed and scan duration cannot be longer than 30 min for 2 bed positions. At a simulated dose of 32 Gy, voxel dose uncertainty is 41%. This reach an acceptable value of 11% for dose larger than 1000 Gy.Conclusion: noise from statistics and reconstruction intrinsically limit the accuracy of voxel dosimetry, which is strongly penalized in 90Y-PET with LYSO.

OP615

Improved treatment planning in radioimmunotherapy with 90Y-anti-CD66 antibody using population based modelling

C. Maaß[1], P. Kletting[2], D. Hardiansyah[1], B. Mahren[3], D. Bunjes[2], A. Beer[2], G. Glatting[1]; [1]Medical Radiation Physics/ Radiation Protection, Medical Faculty Mannheim, Heidelberg University, Mannheim, GERMANY, [2]Department of Nuclear Medicine, Ulm, GERMANY, [3]Department of Nuclear Medicine, Würzburg, GERMANY.

Aim: Accurate estimation of time-integrated activity coefficients is essential for treatment planning in radioimmunotherapy (RIT). Recently it was shown that for the estimation of these coefficients, the application of physiologically based pharmacokinetic (PBPK) models is advantageous over the standard approach (sums of exponential functions) [1, 2]. However, the prediction accuracy of therapeutic biodistributions needs to be further improved. Including knowledge about the population itself, e.g. population specific Bayesian parameters, may serve this purpose. Therefore, the aims of this work were 1) to estimate population parameters and 2) to show the effect of these

parameters on prediction accuracy of therapeutic biodistributions. Materials and Methods: Population parameters were estimated two-fold, i.e. using the standard and iterated two-stage (STS, ITS) algorithms. For each algorithm, a PBPK model was fitted to pre-therapeutic (gamma camera and serum) and therapeutic (serum) measurements simultaneously. The estimated population values (STS, ITS) were implemented as Bayesian information. The model parameters of each patient were fitted to pre-therapeutic data only, therapeutic biodistributions simulated. Prediction accuracy of the therapeutic serum curve was validated comparing the simulated and fitted time-integrated activity coefficients. Results: The relative deviations RDs between pre-therapeutic and therapeutic serum time-integrated activity coefficients are (-25 ± 16) %. When using no Bayes parameters prediction accuracy was RD = (-3 ± 20) %. Using population based parameters as Bayesian information improved RD to (8 ± 16) %) and (0 ± 10) % for the STS and ITS algorithm, respectively. Conclusion: Estimation and subsequent application of population values used as Bayesian parameters for RIT using a PBPK model for 90Y labeled anti-CD66 antibodies improves prediction accuracy substantially. Literatur: 1. Maaß C and Kletting P, Reske SN, Beer A, Glatting G. Physiologically Based Pharmacokinetic Modeling is Essential in 90Y-labeled Anti-CD66 Radioimmunotherapy. Metrology for molecular radiotherapy: what did the MetroMRT project achieve?

V. Smyth[1], C. Bobin[2], L. Johansson[1], L. Joulaeizadeh[3], M. D'Arienzo[4], M. Capogni[4], H. Rabus[5], M. Cox[1], J. Šolc[6]; [1]National Physical Laboratory, Teddington, Middlesex, UNITED KINGDOM, [2]Laboratoire National Henri Becquerel/Commissariat à l'Energie Atomique (LNE-LNHB), Gif-sur-Yvette Cedex, FRANCE, [3]VSL, Dutch Metrology Institute, Delft, NETHERLANDS, [4]National Institute of Ionizing Radiation Metrology, ENEA-INMRI, Rome, ITALY, [5]Physikalisch-Technische Bundesanstalt (PTB), Braunschweig, GERMANY, [6]Czech Metrology Institute (CMI), Prague, CZECH REPUBLIC.

The MetroMRT project was funded through the European Metrology Research Programme (EMRP http://www.emrponline.eu/). It ran from June 2012 to May 2015, and this was the first time that the measurement of radiation absorbed dose to target and normal tissues in the modality of molecular radiotherapy (MRT) had been addressed within the discipline of metrology. The problems of standardisation of procedures, traceability to primary standards, and uncertainty in dosimetry for external beam therapy was covered in the UK by the HPA [1983] and then internationally by IAEA [1987]. This positions MRT approximately 30 years behind external beam therapy in establishing dosimetry to achieve uniformity in practice from one centre to another, or one country to another, and so that absorbed dose in MRT can become a legal quantity able to be specified in regulations.The structure of the MetroMRT project was based on the links in the measurement chain required to obtain absorbed dose within a volume of interest (VOI) in a patient undergoing a typical MRT procedure:1.Measurement of the administered activity;2.Definition and delineation of the VOI (target tissue; normal tissue);3. Quantitative imaging (QI) procedure (tracer activity, full therapy activity, surrogate) to determine activity in the VOI relative to the administered activity;4.Determination of biokinetics from a time sequence of activity measurements interpolated/extrapolated to give an activity-time curve; then obtain total disintegrations within defined VOI by integrating under the curve;5.Calculation of absorbed dose within the VOI (Gy/MBq).Workpackages in the project showed that traceability can be established within links 1, 3, and 5 to primary standards of radioactivity and radiation absorbed dose. A separate workpackage investigated the uncertainty entailed in the choice of how links 2 and 4 were carried out, and showed that by adopting best practice procedures the overall uncertainty in the measurement of absorbed dose can be evaluated.The project has therefore demonstrated that it is technically feasible to formulate a dosimetry protocol for MRT and has given strong recommendations to the relevant international bodies (IAEA, ICRP) that the process should be initiated.HPA, Revised Code of Practice for the dosimetry of 2 to 25 MV X ray, and of 137Cs and 60Co gamma-ray beams, Phys. Med. Biol. 28 (1983) 1097-1104.IAEA, Absorbed Dose Determination in Photon and Electron Beams: An International Code of Practice, Technical Reports Series No. 277, Vienna (1987).

Synthesis and evaluation of Androgen Receptor radioligand [18F]enzalutamide: comparison with [18F] FDHT

I. F. Antunes[1], R. Dost[2], A. van Waarde[1], R. Dierckx[1], D. Samplonius[3], W. Helfrich[3], D. Burg[4], E. de Vries[1], I. de Jong[2]; [1]NMMI, University Medical Center of Groningen, Groningen, NETHERLANDS, [2]Department of Urology, University

Medical Center of Groningen, Groningen, NETHERLANDS, [3]Surgical Research Laboratory, University Medical Center of Groningen, Groningen, NETHERLANDS, [4]Astellas Pharma Europe, Leiden, NETHERLANDS.

Aim: 16β-[^{18}F]fluoro-5α-dihydrotestosterone ([^{18}F]FDHT) is a PET tracer that has been investigated for the assessment of androgen receptor (AR) density in prostate cancer. Being an agonist, [^{18}F]FDHT intrinsically poses the risk pharmacological response, which is undesirable for a PET tracer. Recently, enzalutamide (formerly MDV3100) was introduced as an AR signaling inhibitor. Here we present the synthesis of [^{18}F]enzalutamide and its *in vitro* and *in vivo* behavior in comparison to [^{18}F]FDHT. Methods: The nitro-precursor was obtained by multistep synthesis starting with the nitrobenzoic acid. [^{18}F]enzalutamide was obtained by fluorination of the corresponding nitro precursor. Competition assays with [^{18}F]enzalutamide and [^{18}F]FDHT were conducted in the LnCaP (AR+) cell line to evaluate the affinity for AR. *In vitro* cellular uptake of both tracers were performed with LnCaP (AR+) and HEK293 (AR-) cells. *In vivo* PET imaging, *ex vivo* biodistribution and metabolite studies with [^{18}F]enzalutamide and [^{18}F]FDHT were conducted in athymic nude mice bearing a subcutaneous LnCaP xenograft. Results: The nitro precursor was produced with an overall yield of 2%. [^{18}F]Enzalutamide was obtained in 1.2% radiochemical yield with an apparent specific activity of 487 ± 347 GBq/mmol. [^{18}F]FDHT was obtained in 2% with a specific activity > 25.000 GBq/mmol. Co-incubation of [^{18}F]enzalutamide or [^{18}F]FDHT with an excess of DHT or enzalutamide significantly reduced cellular uptake of both tracers to about 50% in AR+ LnCaP cells, whereas co-incubation of both tracers with an excess of DHT or enzalutamide did not lead to reduction of cellular uptake in the AR- HEK293 cell line. [^{18}F]enzalutamide and [^{18}F]FDHT biodistribution studies in male mice bearing a LnCAP xenograft showed 2.5 times higher [^{18}F]Enzalutamide uptake in tumor than [^{18}F]FDHT. In addition, metabolite analysis indicated that 99% of [^{18}F]Enzalutamide remains intact versus only 3% of [^{18}F]FDHT at 60 min p.i. Conclusion: Based on our results, [^{18}F]enzalutamide seems to have more favorable properties for AR imaging than [^{18}F]FDHT. Additional evaluation in various oncological animal models is warranted to confirm its ability to monitor AR expression.Funding: Prostate Cancer Molecular Medicine 030-203.

Comparison of [11C]Choline and [18F]Galacto-RGD as pharmacodynamic biomarker for therapy response assessment of avastin therapy in a PC-3 Prostate Cancer Xenograft Model

S. Schwarzenböck[1,2], M. Souvatzoglou[1], M. Heuschkel[2], R. Nawroth[3], U. Treiber[3], T. Schuster[4], R. Senekowitsch-Schmidtke[1], M. Schwaiger[1], S. I. Ziegler[1], G. Henriksen[5], H. Wester[5], A. J. Beer[1], B. J. Krause[1,2]; [1]Technical University München, Department of Nuclear Medicine, München, GERMANY, [2]Rostock University Medical Centre, Department of Nuclear Medicine, Rostock, GERMANY, [3]Technical University München, Department of Urology, München, GERMANY, [4]Technical University München, Institution of Statistics, München, GERMANY, [5]Technical University München, Pharmaceutical Radiochemistry, Garching, GERMANY.

Introduction:In prostate cancer molecular imaging development and evaluation of new tracers with higher sensitivity and specificity for diagnosis as well as therapy response assessment is necessary. The use of 18F-labeled Galacto-RGD ([18F]RGD) - targeting the integrin alpha-v-beta-3 as a key molecule in angiogenesis and tumour metastasis - is a promising approach for prostate cancer imaging and therapy response assessment.Aim:The aim of this study was to compare the properties of [18F]RGD and [11C]Choline ([11C]CHO) as imaging biomarker and to assess response to an anti-angiogenesis avastin therapy avastin in a PC-3 human prostate cancer xenograft mouse model.Methods:We carried out a dual tracer small animal PET/CT study comparing the properties of [18F]RGD and [11C]CHO in prostate cancer imaging as well as in avastin therapy response assessment (9 untreated mice, 7 avastin therapy mice (5 i.p. injections within 10-13 days, dose of 5 mg/kg bodyweight each), 3 PBS i.p. control mice). The androgen-independent human prostate tumour cell line PC3 was implanted subcutaneously in the flanks of SCID mice. 6 weeks post xenografting all mice underwent dynamic PET/CT scanning after injection of 37 MBq [11C]CHO and 14 MBq [18F]RGD, respectively, via the tail vein on two separate days. 5x5x5 mm VOIs were placed in transaxial slices in tumour, muscle (thigh), liver, kidney and blood. Image analysis was performed calculating tumour-to-muscle (T/M) ratios based on summed images.Tumour volumes were measured using a caliper.Results:In untreated mice the mean [18F]RGD T/M ratio was significantly higher compared to [11C]CHO (4.62 +/- 2.20 vs. 1.44 +/- 0.39, mean difference +3.18, 95% CI: 2.12 - 4.25, $p<0.001$), in the PBS control group comparable results were obtained. In contrast, there was a tendency of an increase in both [18F]RGD and [11C]CHO uptake in the avastin treated group. Measurement of tumour volumes showed a decreased tumour growth in avastin treated mice compared to the control group.Conclusion:Excellent tumour visualization is possible in this PC-3 xenograft model using [18F]RGD. [18F]RGD uptake was significantly higher compared to the clinically utilized [11C]CHO. In the avastin treated group there was an increase in [11C]CHO as well as in [18F]RGD uptake (compared to untreated and PBS control mice) indicating a stimulating effect of the humanized monoclonal antibody avastin in the early stage of anti-angiogenesis therapy. Further studies using clinically relevant therapies for

prostate cancer are recommended to assess the general suitability of [18F]RGD therapy response assessment of prostate cancer.

OP619
Broadcasting the HER3 receptor status in vivo

C. D. Martins, C. Da Pieve, D. M. Ciobota, R. L. Paul, T. Spinks, G. Smith, G. Kramer-Marek; The Institute of Cancer Research, London, UNITED KINGDOM.

Background: Amongst the human epidermal growth factor receptor (HER) family, HER3 is a key node in the activation of the PI3K/AKT pathway, implicated in promoting cell survival, proliferation and metastasis. Overexpression of HER3 correlates with advanced disease stage and is involved in resistance to other anti-HER therapies. Multiple anti-HER3 mAbs are being tested in clinical trials, highlighting the potential of HER3 inhibition to improve patient care. We investigated the potential use of affibody molecules targeting HER3 ($Z_{HER3:8698}$) for PET imaging of different receptor levels in HER3+ve breast cancer models. The ultimate goal is to promote $Z_{HER3:8698}$-based imaging agents as tools for patient stratification for anti-HER3 targeted therapies. Materials and methods: $Z_{HER3:8698}$ molecules were conjugated via the C-terminus cysteine with NOTA-Maleimide and DFO-Maleimide for ^{18}F and ^{89}Zr radiolabelling respectively. The probes were characterised *in vitro* using a panel of human breast adenocarcinoma cell lines with different receptor levels (MDA-MB-231_{HER3}<MDA-MB-361_{HER3}<BT-474_{HER3}<MCF-7_{HER3}). BALB/c nu/nu mice bearing BT-474 and MDA-MB-231 xenografts were used for *in vivo* evaluation of the probes. Mice were injected via the tail vein with either of the radioconjugates (1-5 μg, 0.8-14 MBq depending on the tracer). Biodistribution as well as imaging studies were performed 1, 3 and 24 h following ^{89}Zr-DFO-$Z_{HER3:8698}$ injection, and 1, 2 h post ^{18}F-AlF-NOTA-$Z_{HER3:8698}$ administration. Results: The K_d of both ^{18}F and ^{89}Zr conjugates was determined to be within 0.44 ± 0.044 (nM). Pre-incubation with either unlabelled affibody or heregulin reduced binding of both tracers *in vitro*, confirming the specificity of the probes. There was no significant accumulation of the ^{18}F radioconjugate in BT-474 tumour bearing mice 2 h post ^{18}F-AlF-NOTA-$Z_{HER3:8698}$ injection, most likely due to low specific activity of the conjugate (SA: 0.8 MBq/μg). However, the ^{89}Zr probe (SA: 2.8 MBq/μg) specifically accumulated in BT-474 xenografts (2%ID/g) as early as 1 h post tracer injection, but not in MDA-MB-231 tumours ($T_{BT-474}/T_{MDA-MB-231}$: 3.4). Rapid clearance was observed in BT-474 bearing mice leading to high tumour to blood and muscle ratios (T_{BT-474}/Blood: 7, T_{BT-474}/Muscle: 23, $T_{MDA-MB-231}$/Blood: 0.81, $T_{MDA-MB-231}$/Muscle: 4.4). IHC and ELISA receptor evaluation showed correlation with PET signal, *ex vivo* autoradiography, and radioactivity measurements. Conclusion: Our data shows that ^{89}Zr-DFO-$Z_{HER3:8698}$ molecules accumulate with high specificity in HER3+ve tumours, providing real time information about the receptor expression. Various strategies to develop higher SA ^{18}F-radiolabelled $Z_{HER3:8698}$ molecules are being pursued.

OP620
PET Imaging of c-Met in Cancer with ^{64}Cu-Labeled Hepatocyte Growth Factor

H. Luo, H. Hong, S. Shi, S. A. Graves, R. J. Nickles, **W. Cai**; University of Wisconsin-Madison, MADISON, WI, UNITED STATES.

Objective: The hepatocyte growth factor (HGF) and its receptor, c-Met, are actively involved in tumor progression/metastasis and associated closely with poor prognostic outcome of cancer patients. Development of positron emission tomography (PET) agents for assessing c-Met expression would be extremely useful for diagnosis of cancer and subsequent monitoring of responses to c-Met-targeted therapies. Herein we report the expression and characterization of recombinant human hepatocyte growth factor (rh-HGF) as a PET tracer for non-invasive imaging of c-Met expression. Methods: rh-HGF was expressed in human embryonic kidney (HEK) 293 cells and purified by nickel-nitrilogriacetic acid (Ni-NTA) affinity chromatography. The concentrated rh-HGF was conjugated to 2-S-(4-isothiocyanatobenzyl)-1,4,7-triazacyclononane-1,4,7-triacetic acid (p-SCN-Bn-NOTA) and labeled with ^{64}Cu. c-Met binding evaluation by flow cytometry was performed in both U87MG and MDA-MB-231 cell lines, which have high and low level of c-Met, respectively. PET imaging and biodistribution studies were performed in nude mice bearing U87MG and MDA-MB-231 xenografted tumors. Ex vivo histopathology were performed to elucidate the expression patterns of c-Met in different tissues/organs and used to validate the in vivo results. Results: The rh-HGF expression yield was 150-200 μg protein per 5×10^6 cells after 48 h transfection with purity of > 85%. Flow cytometry examination confirmed strong and specific binding capacity of rh-HGF to c-Met. After labeled with ^{64}Cu, PET imaging revealed specific and prominent uptake of ^{64}Cu-NOTA-rh-HGF in c-Met positive U87MG tumors (6.7 ± 1.8 %ID/g at 9 h post-injection; n = 4) and significantly lower uptake in c-Met negative MDA-MB-231 tumors (1.8 ± 0.6 %ID/g at 9 h post-injection; n = 4). Heat-denatured rh-HGF (termed as dnrh-HGF) had significantly lower uptake in U87MG tumors, which confirmed the c-Met specificity of ^{64}Cu-NOTA-rh-HGF. Based on fluorescence staining of c-Met, c-Met expression was prominent on the U87MG tumor cells but absent on the MDA-MB-231 cells and rh-HGF can target c-Met with high specificity. c-Met staining of mouse liver and muscle gave a low signal, indicating that these tissues do not express high level of c-Met. Thus, uptake of ^{64}Cu-NOTA-rh-HGF in

the liver was mostly due to hepatic clearance of the tracer rather than c-Met binding. Conclusion: Herein we report the purification of rh-HGF, the characterization and in vitro/in vivo investigation of ^{64}Cu-NOTA-rh-HGF for in vivo PET imaging of c-Met expression. Fast, prominent and c-Met-specific uptake of ^{64}Cu-NOTA-rh-HGF in the U87MG tumors was observed, which was validated by various in vivo/ex vivo experiments.

OP621

The PET tracer [18F]-tetrafluoroborate allows reporter gene-afforded metastasis tracking.

S. Diocou[1], **G. Fruhwirth**[1], K. Chuamsaamarkkee[1], M. Jauregui-Osoro[1], L. Livieratos[1], P. Blower[1], T. Ng[1,2], G. Mullen[1]; [1]King's College London, London, UNITED KINGDOM, [2]University College London, London, UNITED KINGDOM.

Purpose: We aim to non-invasively track metastasis in a murine breast cancer model by PET/CT. The approach is based on a radionuclide-optical fusion protein as previously described (1). Metastasis tracking has not been shown before using NIS-based PET imaging. Here we compare the PET radiotracer [18F]-BF4- (2) with the SPECT radiotracer [123I]-iodide for NIS reporter gene imaging-afforded detection and monitoring of metastasis. Another goal was to compare metastasis detection and tracking of this NIS-RFP-afforded PET approach with [18F]-FDG PET in this preclinical model.Methods: Breast adenocarcinoma cells (MTLn3E) were engineered to stably express the sodium iodide symporter (NIS) fused to a fluorescent protein for multimodal multi-scale imaging. Furthermore, we transduced MTLn3E.NIS-RFP cells with full-length or truncated CXCR4 (3E.FL-NIS and 3E.Δ-NIS, respectively). The resultant cell lines served as a model for tumor xenografts that showed a low or very high propensity for spontaneous metastasis (3). Xenografts were established orthotopically in the lower mammary fat pad of female SCID/Beige mice. Dynamic radionuclide scanning using [18F]-BF4-, [123I]-iodide and/or [18F]-FDG tracers was performed by PET/CT and SPECT/CT as appropriate. Specificity and sensitivity of metastasis detection were measured by comparing radionuclide scans with confocal fluorescence microscopy of biopsied lymph node tissues.Results: Uptake of both [18F]-BF4- and [123I]-iodide in primary tumors was rapid, reaching 12.1 and 11.0 %ID/g for [18F]-BF4- and [123I]-iodide, respectively, after 12min, and 56.9 and 60.5 %ID/g, respectively, after 120min. Clearance of [18F]-BF4- from the blood was faster (falling to 0.06 %ID/g at 36 min) than clearance of [123I]-iodide (3.1 %ID/g at 36 min). 100% of lymph nodes (LN) that were detected via [18F]-BF4 PET were also confirmed positive for 3E.Δ-NIS tumor cells using confocal fluorescence microscopy of biopsied material. Furthermore, all LNs that were not detected by [18F]-BF4 PET were confirmed to be free of metastasis. LNs detected by [18F]-BF4- and confirmed to be positive for tumor metastases were not detected using [18F]-FDG in >95% of the cases.Conclusion: [18F]-BF4- PET showed more favorable tracer kinetics and signal-to-background as compared to [123I]-iodide SPECT. Furthermore, it showed much higher sensitivity and specificity for metastasis detection as compared to [18F]-FDG. This preclinical model is particularly useful for studying spontaneous cancer metastasis and for evaluating the treatment response of anti-cancer and particularly anti-metastatic therapeutics.References:(1) Fruhwirth J Nuc Med 2014; 55(4):686-94.(2) Jauregui-Osoro Eur J Nucl Med Mol Imaging, 2010; 37(11):2108-16.(3) Vermeer J Proteome Res 2012; 11(5):2996-3003.

OP622

Molecular imaging of EGFR and EGFRvIII for prediction and response monitoring of HSP90 inhibition in an in vivo squamous cell carcinoma model

D. Spiegelberg[1], A. C. Mortensen[1], R. K. Selvaraju[2], O. Eriksson[2], B. Stenerlöw[1], A. Scott[3], M. Nestor[1,4]; [1]Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, SWEDEN, [2]Preclinical PET Platform, Uppsala, SWEDEN, [3]Ludwig Institute for Cancer Research, Olivia Newton-John Cancer Research Institute, and La Trobe University, Melbourne, AUSTRALIA, [4]Department of Surgical Sciences, Academic hospital, Uppsala, SWEDEN.

Aim: The novel HSP90 targeting drug AT13387 has been shown to reduce tumor growth, angiogenesis and spreading of the disease in patients with solid cancers. Remaining challenges are to increase response rates and prolong response duration by refining treatment dose and schedules. Molecular imaging of biomarkers involved in disease progression is a useful noninvasive tool to obtain this goal. Biomarkers that are over expressed or tumor specific in several malignancies are e.g. the epidermal growth factor receptor (EGFR) and the epidermal growth factor receptor variant III (EGFRvIII). The overall goal of this study was to identify if EGFR or EGFRvIII expression monitoring in squamous cell carcinomas (SCC) could be used in order to follow the disease status during AT13387 treatment. Materials and methods: Cancer cell proliferation, cell toxicity assays and radio-immunoassays using radiolabelled monoclonal antibodies targeting EGFRvIII and EGFR, were used to quantify the effect of AT13387 on antigen expression in vitro. Inhibitor effects were then assessed in vivo in mice xenografts bearing dual SCC tumors with high or low EGFR expression, and low EGFRvIII expression. Animals were treated 5 times on 5 consecutive days with AT13387 (50 mg/kg), and were then imaged either with 18F-FDG (30 min p.i.), 124I-labelled EGFR-targeting mAb Cetuximab, or with an 111I-labeled anti-EGFRvIII antibody (48 h p.i.).

Imaging was performed with a small animal PET/CT or SPECT/CT, and was followed by ex vivo biodistribution and autoradiography measurements and immunohistochemical analysis. Results and conclusion: We could demonstrate for the first time that the HSP90 client protein EGFRvIII is downregulated, approximately by 30% in our models, by AT13387. We could also verify that EGFR is downregulated by AT13387 in SCC, approximately by 75% and 40% in our high- and low-EGFR-expressing models respectively. 18F-FDG was neither able to clearly detect nor distinguish between EGFR expression. We conclude that the 111In-labelled EGFRvIII-targeting antibody and 124I-cetuximab are promising tracers for EGFRvIII and EGFR expression analysis respectively, and could be useful tools for treatment response monitoring in combination with HSP90 inhibition in SCC patients.

OP623

Efficacy of the sequentially combined vinorelbine and gefitinib in Non-Small Cell Lung Cancer cell lines, an "in-vivo" study.

G. Bottoni[1], M. Dal Bello[2], A. Alama[2], S. Morbelli[1], C. Marini[3], F. Grossi[2], G. Sambuceti[1]; [1]1.Nuclear Medicine Unit, IRCCS-IST San Martino, University of Genoa, Genova, ITALY, [2]Lung Cancer Unit IRCCS-IST San Martino, Genova, ITALY, [3]3.Institute of Bioimaging and Molecular Physiology, CNR, Milan, Genoa Section, Genova, ITALY.

Aim: The current standard of care for advanced NSCLC is based on systemic chemotherapy or epidermal growth factor receptor tyrosine kinase inhibitors (EGFR-TKI) for patients with tumors harboring EGFR mutations. Preclinical studies suggest that EGFR-TKI may have additive effects on chemotherapy even in cancers without EGFR mutations. Our study tested, in vitro and in vivo, the anti-proliferative activity of different treatment schedules with gefitinib (GEF) and vinorelbine (VNB) in EGFR-TKI resistant NSCLCs.Methods: We studied CD1-Nude mouse subcutaneously inoculated with 3 millions H1975 cells in the dorsal hip. In each mouse, cancer growth was estimated by conventional caliper methods, while lesion glucose consumption was estimated by means of a dynamic PET scans at day 14 after tumor implantation. To this purpose, a bolus of 3-6 MBq of 18F-FDG was injected through a tail vein during a list mode acquisition lasting one hour using a dedicated microPET system. After framing rate optimization, pixelwise maps of cancer glucose consumption (MRGlc) were created using a dedicated software (PMOD) and applying Patlak graphical approach.Results: In vitro short and long-term studies demonstrated that the sequence of VNB followed by GEF was more effective than GEF followed by VNB or the concurrent administration of the two drugs. Moreover, the increased antitumor activity of the sequence VNB followed by GEF was confirmed in vivo by a significant inhibition of the H1975 tumor growth (0,13 ml vs 0,95 ml in treated and untreated lesions, respectively, $p<0.05$). This biological effect was correctly predicted by FDG-based measurement of lesion MRGlc that was 2,81±0,04 umol/min/100gr in untreated and 5.65±2.71 umol/min/100gr in treated mice, respectively ($p<0.008$).Conclusion: Our preclinical findings in NSCLC with EGFR T790M mutation showed that the sequential treatment with VNB followed by GEF can induce significant antitumor benefit to be tested in a clinical trial for TKI resistant NSCLC patients.

OP624

Oncologic Applications of High Resolution In Situ Correlations between Histopathology and FDG Tracer Uptake Obtained by Quantitative Autoradiography of Biopsy Specimens (QABS)

A. S. Kirov[1], L. M. Fanchon[1,2], S. Dogan[1], C. Czmielewski[1], E. Yorke[1], H. Schöder[1], J. O. Deasy[1], J. L. Humm[1], S. B. Solomon[1]; [1]Memorial Sloan-Kettering Cancer Center, New York, NY, UNITED STATES, [2]INSERM, UMR1101, LaTIM, Brest, FRANCE.

Purpose. To use autoradiography to determine the distribution of a PET radiotracer in biopsy specimens obtained under PET/CT guidance for correlation with histopathology and to identify the potential and the limitations of this method for different applications in oncology.Methods. Autoradiography (ARG) using imaging plates was performed on 32 core needle biopsy specimens obtained from different body locations under FDG PET/CT guidance in an interventional suite equipped with a PET/CT scanner. In this institutional review board-approved study, the specimens were extracted using 11G, 13G, 18G and 20G core needles and the response of the plates for 18G and 20G needles was calibrated using gelatin based standards with known activity prepared using the same needles. The quality of the autoradiography image, the preservation of the shape of the specimen during pathology processing, the location of the needle with respect to the PET avid region, the effect of motion on the accuracy of the fused PET/CT image, and the post biopsy management of the patient were all considered in the evaluation of the methodology for different oncologic applications.Results. Of the 32 cases, 18 were found useful for high resolution in situ correlations of tracer uptake with histopathology. Such correlations allowed separating malignant from benign liver lesions based on the activity contained in the specimens which was expressed as SUV_{ARG} (Fanchon et al, JNM, 56, p. 538, 2015). A potential application of this result is evaluating the adequacy of PET guided biopsy needle placement. Eight of the 18 cases were found adequate for calibrating the PET display window and for providing a

ground truth point for evaluation of lesion segmentation contours on the PET image. Two cases showed correlation with inflammation in a normal tissue specimens, and 1 showed uptake in the absence of histopathologic changes in the investigated slices. The percentage of specimen autoradiographs, which can be accurately correlated with histopathology has increased due to improvements of the method since implementation and further increase is expected. Thirty of the patients were treated in our institution. Investigating correlations of QABS findings with treatment outcome is possible for radiation therapy (2 cases), ablation (6 cases) and chemo or antibody therapy (14 cases).Conclusions. QABS is a promising method for providing knowledge which may have an impact on PET tracer validations for nuclear medicine, on the accuracy of interventional radiology and radiotherapy procedures, and on increasing the sensitivity of histopathology assessment of biopsy specimens.

Textural analysis of baseline 18F-FDG PET for predicting treatment response and prognosis in patients with locally advanced esophageal cancer

X. Sun, L. Sun, L. Xing; Shandong Cancer Hospital and Institute, Jinan, CHINA.

PURPOSE: Textural features on baseline 18F-FDG PET have shown the potential role in predicting treatment response in mixed stage esophageal cancer. This study is aim to investigate the value of this new technique for locally advanced esophageal squamous cell cancer (ESCC) receiving chemoradiotherapy. METHOD AND MATERIALS: Under a waiver from institutional review board, 48 patients with newly diagnosed locally advanced ESCC who treated with concurrent chemoradiotherapy were retrospectively reviewed. Thirty-nine patients with early stage ESCC were included as control. All patients underwent pretreatment whole-body 18F-FDG PET/CT. Fifty-four texture indices describing global, local, and regional features were measured in addition to 5 conventional indices as standardized uptake values (SUVs, including maximum, peak, and mean SUV), metabolic volume (MV), and total lesion glycolysis (TLG). Patients were classified as responders (R, complete or partial response) and non-responders (NR, stable or progressive disease) according to RECIST1.1. Progression-free survival (PFS) and overall survival (OS) were recorded. The prognostic significance of parameters was examined using receiver-operating-characteristic curves, Kaplan-Meier analysis, and Cox regression analysis. RESULTS: Both intratumor heterogeneity and mean/peak intensity of FDG uptake were significantly higher in locally advanced ESCC than those in early stage. Thirty-four texture indices, MV, and TLG showed the ability to differentiate R from NR. Nine texture indices showed higher sensitivity (76.7%~86.7%) and specificity (77.8%~94.4%) than MV (76.7% and 83.3%) and TLG (73.3% and 83.3%). Ten texture indices and MV were hazard factors of PFS and OS. Large-zone emphasis, one of the regional texture indices, was the only independent predictor of survival, with hazard ratio of 4.22 (95%CI:1.83~9.72) for PFS and 3.90 (1.74~8.79) for OS. None of the SUVs could predict treatment response and survival. CONCLUSION: FDG PET texture indices provide better predictive information than conventional parameters for locally advanced ESCC. Therefore, the clinical application of FDG PET texture analysis could be an important step in personalized treatment of esophageal cancer.

OP626

The predictive value of ^{18}F-FDG PET-CT for assessing the clinical outcomes in locally advanced NSCLC patients after a new induction treatment: "low-dose" fractionated radiotherapy with concurrent chemotherapy

M. Mattoli[1], M. Massaccesi[2], V. Scolozzi[1], A. Castelluccia[2], G. Mantini[2], A. Giordano[1], M. Calcagni[1]; [1]Institute of Nuclear Medicine, Rome, ITALY, [2]Department of Radiation Oncology, Rome, ITALY.

Aim: Many patients with locally advanced non-small-cell lung cancer (NSCLC) have a poor prognosis, despite the use of two cycles of induction chemotherapy performed before the standard treatment (chemo-radiotherapy). It is emerging that the addition of "low-dose" fractionated radiotherapy (LD-RT) to the induction chemotherapy can enhance tumor cells chemo-sensitivity and improve its effects. Aim: to evaluate whether the metabolic response assessed by ^{18}F-fluoro-deoxyglucose positron emission/computed tomography (^{18}F-FDG PET-CT) after induction chemo-LD-RT can predict clinical outcomes in locally advanced NSCLC patients. Materials and methods: Forty-two consecutive locally advanced NSCLC patients (32 males, mean age 66±7.9years; 25 stage IIIA; 17 stage IIIB) underwent LD-RT (40cGy twice daily) to primary tumor and involved lymph-nodes concurrently with two cycles of induction chemotherapy, before undergoing standard chemo-radiotherapy treatment. ^{18}F-FDG PET-CT was performed before (mean 5.7±2 weeks) and after chemo-LD-RT (mean 4.6±1.5 weeks). SUVmax of primary tumor and of the most active lymph-node was evaluated in both PET-CT to obtain the metabolic changes (ΔSUV). To assess the metabolic response, PERCIST criteria were used. Patients with complete and partial metabolic response were classified as responders; patients with stable and progressive disease as non-responders. Disease free survival (loco-regional, distant

or global) and overall survival were calculated with Kaplan-Meyer method. Results: Twenty out of 42 locally advanced NSCLC patients (48%) were classified as responders: 22/42 as non-responders. Two years loco-regional failure free survival was 54%: 84.4% in responder and 24.8% in mom-responders (p=0.001). Two years distant failure free survival was 48.2%: 70.4% in responders and 22.8% in non-responders (p=0.001). Two years global failure free survival was 34%: 63.4% in responders and 0.8% in non-responders (p=0.0003). Two years overall survival was 58.2%: 73.5% in responders and 43.9% in non-responders (p=0.009). SUVmax of primary tumor and lymph-node was significantly reduced at PET-CT after chemo-LD-RT (p=0.004 and p=0.0002, respectively). No significant difference in SUVmax between stage IIIA and stage IIIB was found, either at diagnosis or after chemo-LD-RT. **Conclusion**: in patients with locally advanced NSCLC, ^{18}F-FDG PET-CT is useful for assessing metabolic response after a new induction treatment, such as" low-dose" fractionated radiotherapy with concurrent chemotherapy. Metabolic response predict clinical outcomes: patients with complete or partial metabolic response have a better prognosis than those with progressive or stable disease. These findings allow to personalize therapy, selecting patients for standard treatment or for intensified treatment.

OP627

Comparison of EORTC criteria and PERCIST for FDG PET/CT response evaluation of patients with metastatic breast cancer treated with a first line of systemic therapy.

E. Depardon[1], S. Kanoun[1,2], O. Humbert[1,2], J. Riedinger[1], M. Lasserre[1], M. Toubeau[1], A. Berriolo-Riedinger[1], I. Dygai-Cochet[1], P. Fumoleau[3], F. Brunotte[1,2], A. Cochet[1,2]; [1]Department of Nuclear Medicine, Centre Georges-Francois Leclerc, Dijon, FRANCE, [2]Le2i CNRS UMR 6306, Dijon, FRANCE, [3]Department of Medical Oncology, Centre Georges-Francois Leclerc, Dijon, FRANCE.

Aim : To compare European Organization for Research and Treatment of Cancer (EORTC) criteria with PET Response Criteria in solid Tumors (PERCIST) for response evaluation of patients with newly diagnosed metastatic breast cancer treated with a first line of systemic therapy.Methods : From December 2006 to august 2013, 57 patients who were referred to our institution for a newly diagnosed metastatic breast cancer were retrospectively included (41 HR+/HER2-, 9 HER2+, 7 triple negative). FDG-PET/CT was performed within one month before treatment and 3 to 9 months following start of a first line of systemic therapy: polychemotherapy (n=20), bevacizumab-based therapy (n=16), hormone therapy (n=12) or trastuzumab-based therapy (n=9). Response evaluation with FDG-PET/CT was retrospectively performed according to both EORTC criteria and PERCIST, classifying the patients into 4 response groups: complete metabolic response (CMR), partial metabolic response (PMR), stable metabolic disease (SMD), and progressive metabolic disease (PMD). The kappa statistic was used for agreement analysis. Overall survival (OS) within every response categories was determined by Kaplan-Meier method after a median follow up of 30 months. A multivariate analysis was also performed by Cox model to assess independent predictors of survival.Results: Average time delay between baseline and follow-up PET/CT was 5 months. With EORTC criteria, 22 patients had CMR, 17 had PMR, 6 had SMD and 12 had PMD. With PERCIST, 20 patients had CMR, 15 had PMR, 10 had SMD and 12 had PMD. There was agreement between EORTC and PERCIST in 84% of the patients, and the corresponding kappa-coefficient was 0.78. Thirty patients died during follow up (8 CMR, 12 PMR, 2 SMD, 8 PMD with EORTC; 7 CMR, 10 PMR, 4 SMD, 9PMD with PERCIST). By log-rank analysis, metabolic response evaluated with both EORTC and PERCIST was able to predict survival (p=0.028 and 0.002 respectively). Patients in the CMR group had longer median OS than patients in the combined PMR+ SMD+PMD group (60 vs 26 months; p=0.009 with EORTC; p=0.006 with PERCIST). By multivariate analysis, CMR either with EORTC or PERCIST, stratified by age and phenotype, remained an independent predictor of survival.Conclusion: In the setting of metastatic breast cancer treated with a first line of systemic therapy, metabolic response evaluation with EORTC criteria and PERCIST gave similar response and outcomes with good agreement and similar significant differences in median OS between response groups.

OP628

Monitoring Tumour Response to Neoadjuvant Chemotherapy using MRI and ^{18}F-FDG PET/CT in Breast Cancer Subtypes

A. M. T. Schmitz[1], K. E. Pengel[2], C. E. Loo[2], W. Vogel[2], J. Wesseling[2], **S. C. Teixeira**[2], E. J. T. Rutgers[2], R. A. Valdés Olmos[2], G. S. Sonke[2], S. Rodenhuis[2], M. T. F. D. Vrancken-Peeters[2], K. G. A. Gilhuijs[1]; [1]University Medical Centre Utrecht, Utrecht, NETHERLANDS, [2]Netherlands Cancer Institute - Antoni van Leeuwenhoek Hospital, Amsterdam, NETHERLANDS.

Aim: To establish a practical guideline on the use of MRI and/or PET/CT for response monitoring of the primary tumour, taking into account the breast cancer subtypes. Material & Methods: We included 188 women with stages II/III breast cancer. Baseline histology was assessed from biopsy. Primary tumours were stratified into ER-positive/HER2-negative (ER-positive), HER2-positive, and ER-negative/HER2-negative/PR-negative (triple-negative) subtypes, and treated with pre-operative neoadjuvant chemotherapy (NAC) according to subtype. MRI and ^{18}F-FDG-PET/CT were acquired before and during NAC. Primary

endpoint was pathological complete response (pCRmic) defined as no or only small numbers of scattered invasive tumour cells. Multivariate analyses assessed the association of patient, tumour and imaging characteristics with pCRmic. Using post-hoc analysis, six imaging scenarios were evaluated; MRI only, PET/CT only, and combinations of both. We used receiver operating characteristics analysis with assessment of areas under the curve (AUC) to determine optimal imaging scenarios and we selected high specificity (90%) as operating point to propose clinical guidelines per subtype. Results: A pCRmic was found in 35/46 (76.1%) of HER2-positive, 11/87 (12.6%) of ER-positive, and 31/55 (56.4%) of triple-negative tumours. Before NAC, age ($p<0.001$) and subtype ($p<0.001$) were the only predictors of response. During NAC, MRI yielded the strongest predictor for HER2-positive tumours (AUC: 0.735; sensitivity 36.2%) outperforming PET/CT (AUC: 0.543; $p=0.04$) comparable to results of combined imaging (AUC: 0.708). In ER-positive tumours, the combination of MRI and PET/CT yielded the strongest predictor (AUC: 0.818; sensitivity 55.8%) compared to MRI (AUC: 0.742) or PET/CT (AUC: 0.791) alone. For triple-negative tumours, MRI (AUC: 0.855; sensitivity 45.4%), PET/CT (AUC: 0.844) or a combination of both showed comparable results (AUC: 0.868). Conclusion: For response monitoring in ER-positive primary tumours the combination of PET/CT and MRI may be the most optimal choice. For HER2-positive and triple-negative tumours, MRI has high specificity but moderate sensitivity to monitor response. PET/CT will provide comparable results with MRI in triple-negative but not in HER2-positive breast cancer tumours.

OP629

Planning of radiotherapy with PET: Volumes only?

M. Beresova, J. Mucientes Rasilla, B. Rodriguez Alfonso, I. Zapata Paz, A. De la Torre Tomas, J. Romero Fernández, M. De Teresa Herrera, I. Plaza De Las Heras, M. Mitjavila Casanovas; HUPH Majadahonda, Madrid, SPAIN.

Aim: We assess the percentage of cases in which findings of distant disease through 18F-FDG PET/CT for radiotherapy planning lead to changes in the modality and/or intent of the treatment, or change in stage IV.Material and methods: All the studies derived from the Radiotherapy department were retrospectively analysed. Those performed for radiotherapy planning were selected. Cases with distant disease findings were assessed, investigating changes in the modality or intent of treatment and change in stage IV.One thousand four hundred seventy six studies were derived from the Radiotherapy department between April/09 and December/13. Three hundred and seventy three (25,3%) were performed for radiotherapy planning (267 males and 106 females, mean age 68.2 years). The intention of radiotherapy was for radical treatment planning.Results: In 45 of these studies (12%) there were previously not suspected findings that suggested an upstage of the patients to a clinical stage IV. The unexpected disease was located more frequently in bone (12 patients), followed by lung (9 patients), liver (10), distant adenopathy (6 patients), brain (4 patients), adrenal glands (4 patients), spleen (1 patient) and multiple progression (1 patient).In twenty-six (26/45, 7%) of these patients the findings of 18F-FDG PET/CT were confirmed as true positive for distant metastasis with complementary examinations. In sixteen (16/26) of them the modality of treatment was changed. In ten of them (10/26) the intent of treatment was changed from curative to palliative. In three patients a second primary tumour was confirmed.In remaining sixteen (16/45) patients the results of 18F-FDG PET/CT could not be initially confirmed. The confirmation was made by monitoring progression in eleven patients, one patient remained with stable disease and four patients died without being able to confirm the findings.Conclusions: 18F-FDG PET/CT studies in radiotherapy planning improve the staging of patients, leading to an upstage in a significant number of patients. Based upon the findings of 18F-FDG PET/CT, the modality or the intent of treatment may radically change, (making unnecessary radiation) or changing the intent to palliative.

OP630

Feasibility and clinical utility of 4D PET/CT for SBRT planning of liver tumors

E. Deshayes[1], L. Santoro[1], M. Eberle[1], S. Guillemard[1], F. Marre[1], N. Aillères[2], P. Fenoglietto[2], D. Azria[2], P. Kotzki[1], O. Riou[2]; [1]Nuclear Medicine Department - Institut Cancer Montpellier, Montpellier Cedex 5, FRANCE, [2]Radiotherapy Department - Institut Cancer Montpellier, Montpellier Cedex 5, FRANCE.

Aim: the aim of this study was to assess the feasibility of 4D PET/CT for patients with liver tumors, and its clinical utility for stereotactic body radiation therapy (SBRT) planning. Material and methods: we retrospectively analyzed in this study all the consecutive patients who underwent 4D PET/CT for liver SBRT radiotherapy planning in treatment position. The patients were included between January 2014 and February 2015. Patients with hepatocellular carcinoma could have undergone either FDG or F-Choline PET/CT. 4D PET/CT images were produced using a Real time Position Management system (RPM, Varian Medical System) and separated in 10 phases (bins). Each phase was then coregistered with each of the 10 phases of the radiotherapy planning 4D CT. All images were independently reviewed by a radiation oncologist and a nuclear medicine physician. Evaluation criteria were: to assess if uptake was significant on 3D PET, on 4D PET, the added

value of 4D PET over 3D PET (leading to a change in target volumes). Impact of PET/CT on treatment decision was also reported. Results: 15 patients (14 males, 1 female) were included: 10 primary tumors (3 patients with hepatocellular carcinoma performed a F-Choline PET/CT; 7 had FDG PET/CT: 5 hepatocellular carcinoma and 2 cholangiocarcinoma) and 5 metastatic liver lesions (3 from colorectal cancer, 1 from breast cancer and 1 from renal cell carcinoma). Mean age was 73.6 years (+/- 7.3). Final analysis was performed on 13 patients as PET/CT led to exclude 2 patients for SBRT (discovery of multiple unknown distant metastases). Among the 13 remaining patients, the nuclear medicine physician found a significant and useful 4D PET/CT liver uptake as compared to 3D PET/CT for 7 patients (54 %), and the radiation oncologist for 9 patients (the same 7 patients and 2 more) (69 %). Among those 9 patients, 4D PET/CT led to an effective change in radiotherapy volumes for 8 patients. For the 7 patients whose 4D PET/CT was considered as useful for both nuclear medicine physician and radiation oncologist, the mean SUVmax of the liver lesions determined on 4D acquisition was 12,4 mg/mL (+/- 2,8) versus 10,6 g/mL (+/-2,3) on 3D PET/CT. Conclusion: 4D PET/CT appears to be feasible and useful for stereotactic body radiation therapy planning of hepatic tumors.

OP631

Other than restaging phase: Serial FCH PET/CT scans can predict the response to chemotherapy in castrate-resistant prostate cancer?

L. Evangelista[1], U. Basso[1], A. Guttilla[2], F. Zattoni[2], A. Cervino[1], M. Maruzzo[1], V. Zagonel[1], F. Zattoni[2], G. Saladini[1]; [1]Istituto Oncologico Veneto I.R.C.C.S., PADOVA, ITALY, [2]University of Padua, PADOVA, ITALY.

Objectives. The present study aimed to evaluate the utility of serial FCH PET/CT scans to predict the response to chemotherapy in patients with castrate-resistant prostate cancer (CRPCa).Materials and methods. We collected FCH PET/CT data from a consecutive series of 21 CRPCa pre-treated patients (median age: 73 years) who meet the inclusion criteria (mainly, visceral and no-visceral metastasis with a clear uptake on a baseline FCH PET/CT scan and no fewer than two scans separated by at least one month and by no more than 12 months while receiving chemotherapy), in our Institute from June 2010 to October 2014. All patients had at least two FCH PET/CT scans, before and after or during chemotherapeutic treatment (taxanes in 17 patients and abiraterone acetate in 4 patients). Change in FCH uptake (SUVmax of the index lesion; ΔSUVmax) during the course of treatment was compared with clinical assessment response and PSA change (ΔPSA). The correlations were evaluated by using Kruskal-Wallis test for K independent variables, linear regression analysis and Kendall rank correlation coefficient. A $p<0.05$ value was considered statistically significant.Results. The median interval time between PET scans was 5 months (3-11 months). Median (range) PSA value and SUVmax of the index lesion were 25 (1.2-1040) ng/mL, 15.7 (5.9-30.2), 22.9 (2.3-1699) ng/mL and 5.5 (3.2-12.2) respectively at the time of baseline and 2nd PET/CT scan. The median ΔPSA and ΔSUVmax were -49.9 and 8.3, respectively. No correlation between ΔPSA and ΔSUVmax was found ($R=0.046$; $p=0.843$). In accordance with the clinical assessment, 8 (38%) patients were responders, 4 (19%) had a stable and 9 (43%) a progressive disease. A significant overlap was reported for ΔPSA and clinical categories of response ($p=0.685$). Conversely, ΔSUVmax was significantly different in patients with response to chemotherapy as compare to those with stable and progressive disease ($p=0.005$).Conclusions. The change in SUVmax, rather than ΔPSA, represents an important measure of response to chemotherapy and should be useful to stratify the prognosis of CRPCa patients. A large multicenter prospective study is necessary to confirm these findings.

OP632

Role of ^{11}C-CHOLINE PET/CT in the Radiotherapy Treatment Planning of Prostate Cancer Patients

E. Lopci, G. R. D'Agostino, C. Franzese, E. Villa, M. Rodari, M. Scorsetti, A. Chiti; Humanitas Clinical and Research Hospital, Rozzano (Milano), ITALY.

Purpose: In the era of image-guided radiotherapy (IGRT), consisting evidence demonstrates that PET imaging can play a significant role in tumour delineation for several neoplasia. However limited data are available on the use of ^{11}C-Choline PET/CT in radiotherapy (RT) planning for prostate cancer patients. The aim of this study was to verify the impact of this imaging modality in treatment planning of patients eligible for RT. Materials and Methods: For the analysis, we enrolled 37 consecutive patients (mean age 70 years, range 53-85) referred to our Institution for radiation therapy planning with a radical intent (n=7), as salvage therapy (n=15) or in order to plan a re-irradiation (n=15). Patients were submitted to a single-day protocol, including dedicated CT scan of the pelvis and ^{11}C-Choline PET/CT scan. Clinical-tumor volumes (CTV), planning-tumor volumes (PTV) and organs at risk (OAR) were outlined on CT slices with Eclipse Varian Medical System software, whereas Gross tumor volume (GTV)-PET was defined as the area of pathologic uptake and contoured with PETVCAR software on Advantage GE workstation. Results: Among the 7 patients undergoing ^{11}C-Choline PET for a radical radiation treatment, 5 (72%) pts received the planned RT, including 1 pt (14%) with a negative PET. Two (28%) pts showed evidence of positive nodes therefore a boost of dose on pathologic lymphnodes was also delivered. Of the 15 pts candidate to a

salvage RT, 4 (26%) had a negative PET and were irradiated on the prostatic bed as planned. Among the 11 pts with positive PET, 1 (9%) was irradiated only on prostatic bed as planned, 7 (64%) received also a boost on positive nodes, 3 (27%) were not submitted to RT because of the evidence of metastatic disease (2 lungs, 1 bone). Of 15 pts already submitted to RT, and undergoing ^{11}C-Choline PET/CT with a re-irradiation intent, 9 (60%) had a confirmed indication to the planned RT, 1 pt (7%) did not receive RT as planned, having the PET scan showed evidence of lung metastases, 5 (33%) because of a negative exam. Conclusion: In our experience ^{11}C-Choline PET/CT proved to have a significant impact on RT planning of prostate cancer patients, by determining a change in the therapeutic decision in up to 48% of cases, in all the therapeutic settings.

Physics & Instrumentation & Data Analysis: Radiation Exposure & Protection

OP633
Initial experience in the management of radiation protection in clinical use of Ra-223

G. CICORIA[1], F. ZAGNI[1], A. INFANTINO[2], A. CORAZZA[1], D. PANCALDI[1], M. MARENGO[1]; [1]Medical Physics Department, University Hospital "S.Orsola - Malpighi", Bologna, ITALY, [2]Department of Industrial Engineering, Montecuccolino Laboratory, University of Bologna, Bologna, ITALY.

Introduction: 223Ra chloride (Xofigo®) is a novel radiopharmaceutical, currently approved for the treatment of bone metastases of prostate cancer. In this work we studied different radiation protection issues, relevant for both patients and workers, namely the emanation of gaseous 219Rn during the manipulation of the product, the calibration of surface contamination monitors and the presence of long-lived contaminants in the radiopharmaceutical solution. Materials & methods: Presence of 219Rn in the air gap of the vial containing Xofigo was quantified by carefully connecting the vial containing Xofigo and an 11 ml evacuated vial; the procedure was repeated after 5 and 15 minutes. The vial containing the sampled air was then measured in gamma-ray spectrometry. Surface contamination monitors were calibrated by uniformly contaminating three different Rad-Wipe® Smears with a mean activity of (2.18±0.12) kBq of 223Ra and evaluating counts in different positions of the sensitive windows. The investigated instruments were a Berthold LB-124 zinc-sulphide scintillator, Eberline PRM-6GM detector (HP-210 probe) and a Tema Sinergie CPS-51 (TPG46 GM detector). Radionuclidic purity was evaluated by gamma spectrometry of different batches of Xofigo® analyzed 2, 6 and 10 month after the calibration date. All the radioactivity measurements were performed with a spectrometry system equipped with a HPGe detector and multichannel analyzer. The system was properly calibrated in the 59-1836 keV range by means of a multi-radionuclide certified reference solution. Results: 219Rn emanation was 1.2% of the 223Ra activity, at the sampling time. Comparable amounts were found in the samples taken after 5 and 15 minutes. Calibration factors for the probes were (0.013±0.001), (0.09±0.02) and (4.7±0.4) Bq/cps/cm2 for LB124, PRM-6 and CPS-51 respectively. No significant activity of contaminants was detected in the measurements taken at 2 and 6 months after reference date. After 10 months only 227Th was detected (1.7±0.1 Bq). Minimum detectable activity for 226Ra and 228Th was 0.3 Bq. Conclusions: The presence of 219Rn and the quick release from liquid to air makes necessary to dispense 223Ra under ventilated hoods. Calibration of surface contamination meters provided a simple and reproducible way to usefully use these instruments to a first evaluation of surface and skin contamination. The very high radionuclidic purity found for this radiopharmaceutical avoids unjustified dose to patients and allows for easy management of both licensing and waste management issues.

OP634
Risk of Contamination and Incorporation during Preparation and Administering Radium-223-Dichlorid [XOFIGO]

L. Thomas[1], C. Scholl[2], S. Kürpig[3], R. Bundschuh[3], M. Essler[3], H. Ahmadzadehfar[3]; [1]Universitätsklinikum Bonn, Klinim für Neklearmedizin, Bonn, GERMANY, [2]Landesinstitut für Arbeitsgestaltung des Landes Nordrhein-Westfalen, FG 1.3 Strahlenschutz, Düsseldorf, GERMANY, [3]Universitätsklinikum Bonn, Klinik für Nuklearmedizin, Bonn, GERMANY.

Introduction: 223Radium-dichloride(Xofigo) is approved in the EU since November 2013 for treatment of bone metastases of prostate-carcinoma. Xofigo improves the overall survival and is the first alpha-emitter routinely used in medical-application. In most clinically used isotopes external radiation is the main source for radiation-exposure of the staff. However, Ra-223 gives most significant exposure when incorporated. Therefore the aim of this study was to estimate the risk of incorporation for medical staff handling Xofigo. Methods: During 6 month 92 applications with a total administered amount of 528MBq Ra-223 were performed. For risk-estimation of incorporation we measured the contamination in the air with aerosol filters. One in the laminar-air-flow-box(LAF) in which the preparation took place, one attached to the physician and one placed at the patient chair. The latter placed in the height of the face of the physician and the patient respectively. Two days after administration of Xofigo a stool-

sample of the physician was measured as Xofigo is secreted dominantly this way. Gloves worn in the LAF, during injection and cleaning-up were measured for contamination as well as the surgical mask which was worn all the time. At each application day all work-steps were performed by the same physician. Results: Filters from the LAF had a mean activity of 6E-4Bq/l meaning no significant aerosol concentration. The other filters did never show an activity over the quantification limit. In none of the stool samples Xofigo was found over the quantification limit of the method. Contamination measurement of the gloves showed measureable amount of Xofigo when gloves were used during preparation and cleaning-up (1E-1 to 1E4Bq). For the surgical mask in 3 cases a measureable amount of Ra-223 were found (two times 1Bq, 1 time 15Bq), this was most probably caused by cross-contamination when removing the mask. Based on the results of stool-samples and air-filters placed at the physician together with the total activity handled the incorporations factor was estimated according the ICRP model. Conclusion: Stool-samples and filters from the physician and from the application-room let conclude that there is no increased risk of incorporation of Xofigo. However, measurements of the LAF-filter indicated that this is only true for preparation in a LAF. Therefore the use of a incorporation-factor ak=10-7 is justified. Increased activity of Xofigo was found at the gloves, therefore two pairs of gloves with a change of the upper pair between all working steps is strongly recommended to avoid cross-contamination.

OP635

18F-FDG whole body PET/CT: evaluation of effective dose in pediatric patients

F. Zito[1], G. Galetta[2], L. Rossi[2], L. Florimonte[1], E. Orunesu[1], M. Castellani[1], C. Canzi[1], F. Voltini[1], R. Benti[1]; [1]FONDAZIONE IRCCS CA' GRANDA Ospedale Maggiore Policlinico, Milan, ITALY, [2]Scuola di Specializzazione in Fisica Medica Università di Milano, Milan, ITALY.

Aim: To evaluate 18F-FDG PET/CT absorbed dose in pediatric patients to optimize CT acquisition parameters and to improve protection of this high-radiation-sensitive young population.Materials and methods: Eight pediatric patients (age 1-7 years) were retrospectively evaluated. For PET examinations 18F-FDG activity was scaled according to PET scanner sensitivity and body weight of patients (on average 5 MBq/kg) but 37 MBq minimum was injected. Whole-body scans, from head to toe, were acquired after 1 h from the administration with the Biograph TruePoint system(Siemens)having 21.6 cm axial FOV. Images of 3 mm slice thickness were reconstructed with 2 iterations 8 subsets AWOSEM algorithm. All CT scans were carried out with: -automatic control of tube current by setting 60 mAs of reference current, -pitch 0.8, -24x1.2mm beam collimation and -0.5s rotation speed. For four patients CT scans were performed with 120 kV and for the other four with 100 kV. PET effective dose was assessed by multiplying the injected MBq with the ICRP 80 18F-FDG factors (mSv/MBq,interpolated factors to each patient age were used. Based on AAPM report 204, patient-specific-size CTDIvol (CTDIvol_AAPM) was calculated by correcting the scanner CTDIvol with AAPM factors relative to measured patient effective diameter on CT images. CT effective doses were estimated with ImPACT dosimetry calculator, doses referred to adult patient were scaled to pediatric by linear interpolation of Khursheed's factors. Two expert nuclear physicians scored CT image quality based on 1-3 scale, sufficient-good -excellent.Results: The four patients scanned at 100 kV kV had on average 40% reduction of CTDIvol with respect those at 120 kV, without reduction of CT image qualities. The CTDIvol_AAPM corrected for patient specific size was twofold the CTDIvol referred to the standard 32cm phantom size. The sum of PET and CT effective doses ranged from 6.4 to 8.6 mSv; the CT contribute assessed with ImPACT was for six patients on average one half that of PET and was similar to PET for two patients who had CT scans at 120 kV. CT image quality scores were good and excellent, independently on tube kV.Conclusion: This study, even if includes only 8 young patients, confirms the importance to consider the specific body size to estimate exposure dose for PET/CT examinations in young patients. The reduction of kV and then of exposure doses without affecting CT image quality has encouraged our PET/CT Unit to perform CT scans at 100 kV for patients 1-7 years old.

OP636

Efficacy of Clinical Audit on administered activities to paediatric patients undergoing dynamic renal scintigraphy

V. de Sousa[1], F. Lourenço[1], P. Pepê[2], G. Cardoso[1], A. I. Santos[1,3], J. G. Santos[1]; [1]Hospital Garcia de Orta, Almada, PORTUGAL, [2]Escola Superior de Tecnologia e Gestão – Instituto Politécnico de Portalegre, Portalegre, PORTUGAL, [3]Nova Medical School - Universidade Nova de Lisboa, Lisboa, PORTUGAL.

Introduction/Aim: In Europe, every year, more than 6 million paediatric patients, which are more radiosensitive than adults, between 2 to 10 times, undergo a Nuclear Medicine procedure. Thus, there is a need to audit administered activities, in order to evaluate its compliance with adopted Guidelines focused on radiation dose optimization. This study aims to evaluate the efficacy of awareness of technical staff to the results of a previous clinical audit on administered activities to paediatric patients. Methods: A sample of 26 ^{99m}Tc-MAG3 DRS performed to children between July 2014 and April 2015 was collected and a retrospective analysis of gender, age, weight,

administered activity (reported at the time of administration) and reference activity was performed. By reference activity we mean the activity calculated with the Paediatric EANM dosage card, adopted by the Department since its first publication. The results obtained were compared with the ones resulting from a similar analysis performed previously on a sample collected between July 2011 and June 2014 and presented to the staff. Non-parametric tests were used, considering the size of the samples and/or the Non Gaussian distribution of the values. Results: The sample collected between July 2011 and June 2014 comprised 39 females and 50 males with a median age of 36 [8, 108] months and a median weight of 15.0 [8.8, 30.5] Kg. Applying the Related-Samples Signed Rank Test (for a non Gaussian non symmetrical distribution) it was obtained a strong evidence that the statistical median of the differences between the administered and the reference activities was different from zero ($p<0.001$). The median administered activity was 39.5 [31.3, 53.2] MBq and the median reference activity was 28.0 [20.3, 43.3] MBq. These results were presented and discussed with the staff. The second sample, collected between July 2014 and April 2015 comprised 10 girls and 16 boys, with a median age of 11 [3.8, 99] months and median weight of of 9.8 [6.2, 27.2] Kg. Using the Related-Samples Wilcoxon Test (for a non Gaussian symmetrical distribution) there was a statistical evidence that the median of the differences between the administered and the reference activities is equal to zero ($p<0.07$). The median administered activity was 24.1 [18.1, 39.6] MBq and the median reference activity was 21.8 [17.8, 34.4] MBq. Conclusion: Considering the results obtained we confirm that a very simple audit procedure improves awareness and optimization of the practices, and allows acknowledging compliance to Guidelines formally adopted.

OP637

Cumulative Radiation Dose Received by Diagnostic Imaging During Staging and Treatment of Primarily Operable Ewing Sarcoma in Patients Diagnosed in Norway 2005-2012.

B. Johnsen[1], K. Fasmer[1], K. Boye[2], K. Rosendahl[3,4], M. Biermann[1,4], C. Trovik[5,4], S. M. Aukland[3,4]; [1]Centre of Nuclear Medicine and PET, Department of Radiology, Haukeland University Hospital, Bergen, NORWAY, [2]Department of Oncology, The Norwegian Radium, OSLO, NORWAY, [3]Pediatric Section, Department of Radiology, Haukeland University Hospital, Bergen, NORWAY, [4]Department of Clinical Medicine,University of Bergen, Bergen, NORWAY, [5]Ortopedic Section, Department of Surgery, Haukeland University Hospital, Bergen, NORWAY.

Objective. Ewing sarcoma is a malignant tumour mainly affecting children and young adults. Planar X-ray, Ultrasound, Computed tomography (CT), Magnetic Resonance Imaging and Skeletal Scintigraphy constitute the conventional" imaging methods. Methods reflecting the biology of the tumour, like F18 FDG PET-CT, are now emerging. During treatment, studies evaluating renal (glomerular filtration rate (GFR), radioisotope renography) and cardiac function (Multi Gated Acquisition Scan (MUGA)) is performed. There is a growing awareness of potential secondary radiation induced malignancy in children and young adults cured of their primary cancer. This national, population based study summarizes all radiological and nuclear medicine (NM) imaging including F18 FDG PET-CT in diagnostics and treatment of patients with primarily operable Ewing sarcoma. Material and methods. 61 patients below 30 years diagnosed with Ewing Sarcoma in Norway in the period 2005-2012 were identified from the Scandinavian Sarcoma registry in Malmoe. Of these, 20 patients met the inclusion criteria: primarily operable Ewing sarcoma, preoperative chemotherapy with operation in week 11, no metastasis or residual disease in a minimum follow up period of 1 year after diagnosis. The mean age was 15 years (range 4-27). The radiation doses the patients received from all radiological (planar X-ray and CT) and nuclear medicine imaging (MUGA, GFR, radioisotope renography, skeletal scintigraphy and PET-CT) 4 months prior to biopsy date to 12 months after biopsy date, was calculated for each patient using dedicated Monte Carlo based dose estimation software tools. Results. The mean (range) estimated cumulative radiation dose a patient received from all radiological and nuclear medicine imaging including PET-CT was 39 (6-86) mSv. Of this total planar X-ray imaging counted for 3 (0-16) mSv, CT imaging 13 (2 - 28) mSv, nuclear medicine imaging (excluding PET-CT) 17 (2 - 51) mSv and PET-CT 6 (0 - 23) mSv. Conclusion. In this study of children and young adults diagnosed with primarily operable Ewing Sarcoma in Norway in the period 2005-2012, the estimated cumulative radiation dose a patient received during the first year after diagnosis was 39 mSv. Compared to the total radiation burden, the contribution from nuclear medicine imaging was 59 % while PET- CT imaging alone contributed to only 15% of the total radiation dose. This study revealed a wide range, both regarding which diagnostic imaging modalities and examination that is performed on this patient group and also regarding the cumulative doses resulting from these examinations.

OP638

Practical assessment of local diagnostic reference levels for PET/CT scans with 68Ga-DOTA peptides

G. Lucconi[1,2], M. Ranaldo[2], F. Zagni[2], G. Cicoria[2], S. Fanti[3], M. Marengo[2]; [1]Alma Mater Studiorum - Bologna University, Bologna, ITALY, [2]Medical Physics Department, S.Orsola–Malpighi University Hospital, Bologna, ITALY, [3]Nuclear Medicine Department, S.Orsola-Malpighi University Hospital, Bologna, ITALY.

Aim: to establish local Diagnostic Reference Levels (DRL) for PET/CT studies with 68Ga-DOTA peptides. Materials & Methods: a sample of 50 patients undergoing 68Ga-DOTANOC PET/CT was retrospectively studied. Scans were acquired using a Discovery 710 and two Discovery STE PET/CT scanners (GE Healthcare) in a period of three months. The CT acquisition was performed following a "low dose" protocol having the following parameters: 120 kV, 80 mA, 0.8 s/tube rotation, pitch 1.75, collimation 20 mm, and 3.75 mm slice thickness; the PET acquisition lasted 3 min for each bed position, having a length of 15 cm and a superposition of 1.1 cm. Unitary patient doses were automatically dispensed by a μ DDS-A system (Tema Sinergie S.p.A.), scaled according to the weight of the patient and measured with a CAPINTEC CRC 15 PET activity meter. The accuracy of the activity meter was assessed using a NIST traceable standard source of 68Ge/68Ga. DRL for CT acquisition were assessed as the 75th percentile of the distribution of the values of CTDI and DLP. DRL for the administered activity were set as the mean activity in the patients' sample, obtained from the normal distribution fitted to observed activity values. These values were then used to estimate the effective and organ doses for a standard patient through ImPACT CT patient dosimetry calculator and the dose-activity coefficients reported in the literature. Results: since the differences in CTDI values observed among the three scanners were small, the data were pooled, giving DRL of 3.82 mGy for CTDI and 381 MBq cm for DLP. DRL for 68Ga-DOTANOC activity resulted 103 MBq and 1.5 MBq/kg, which is close to the inferior limit stated by international guidelines, revealing the capability of modern PET scanners to obtain diagnostic images with a relatively low amount of radioactive tracer. Effective doses of 5.4 mSv and 2.6 mSv were calculated for the CT and PET part respectively. The organs receiving the highest dose were thyroid, bone surface and thymus (8.5, 7.8 and 6.7 mGy) for the CT acquisition, while kidneys, urinary bladder wall and spleen (9.1, 8.5 and 7.4 mGy) for 68Ga-DOTANOC administration. Conclusions: local DRL have been assessed for 68Ga-DOTANOC PET/CT scans, according to international guidelines. These levels and the dosimetric evaluation performed may be a useful tool for optimization and comparison for other centers approaching this technique.

OP639

External radiation exposure of nuclear medicine personnel using an automatic 18F dispenser

R. Matheoudf, D. Lizio, G. Sacchetti, M. Brambilla; AOU Maggiore della Carità, novara, ITALY.

Aim. Personnel working with radiopharmaceuticals in nuclear medicine are subject to radiation exposure, and fingers are likely to receive the highest dose, especially when handling beta+ emitting radionuclides used in PET imaging. Recently, fully automated systems have been introduced to partition ^{18}F activity from the mother vial directly into syringes ready for automatic patient injection, to reduce both external irradiation and the risk of contamination. The aim of this work was to evaluate the radiation exposure of nuclear medicine personnel during the ^{18}F-fluorodeoxyglucose (FDG) loading and partition procedures performed using the automatic ^{18}F dispenser Karl100™ (TemaSinergie, SpA). Materials and Methods. Dose rate (DR) at close contact to Karl100 was monitored with the inbuilt Geiger Mueller detector (LND71210) for loading, dilution and flushing phases of ^{18}FDG transferring from mother vial into Karl100 dispensing kit and for syringe preparation, on a 4 months period. Finger dose (FD) was measured for both the technician operating on Karl100 and for physician who injected patients with the semiconductor dosimeter NED (Unfors Instruments, Inc.)worn on the finger tip of the non dominant hand and on the finger tip used for activation of automatic patient injector, by the technician and physician, respectively, on a 15 days period. Results. The highest DR were measured during ^{18}FDG mother vial loading phase (mean 25.7 μSv/h, range 9.6-37.3 μSv/h) that lasted about 1 minute. DR during syringe preparation was lower (mean 7.0 μSv/h, range 4.3-13.0 μSv/h). FD were in the range 15-87 μSv/GBq of ^{18}FDG activity (mean 42 μSv/GBq) and 33-83 μSv/GBq (mean 56 μSv/GBq) for technicians and physicians, respectively, and corresponded to the daily workload. These values resulted inferior to the lower FD ranges reported in ORAMED study in 2012.onclusion. Karl100™ guarantees a high level of radiation protection of the workers. In the cautelative hypothesis that the same technician stands at close contact to the Karl100 during both mother vial loading and ^{18}FDG partition of 12 doses per day, by using the highest DR measured, this would result in an effective dose of about 230 μSv/y. In the hypothesis of the same technician working on Karl100, he would have an extremity equivalent dose of 17 mSv/y, while for the same nuclear medicine physician injecting all the patients he would receive 3.6 mSv/y.

Skin dose saving of the staff in 90Y/177Lu PRRT therapy with the Automatic Dose-Dispenser (ADD)

F. Fioroni[1], **E. Grassi**[1], G. Cavatorta[2], S. Rubagotti[1], G. Feliciani[1], M. A. Sarti[1], A. Filice[1], A. Versari[1], M. Iori[1]; [1]IRCCS-ASMN, Reggio Emilia, ITALY, [2]University of Bologna, Bologna, ITALY.

Purpose: Labelling and administration of 90Y-DOTATOC and 177Lu-DOTATOC are very hazardous procedures because of the skin exposure to beta radiation. A variety of methods to decrease this risk has been looked for and the outcome of one of them is hereby evaluated. Aim was to investigate the equivalent dose saving of the staff working with 177Lu and 90Y in a nuclear medicine unit, when changing from an essentially

manual radiolabelling procedure to a semi automatic synthesizer ADD.Methods: Chemist and physician are the figures exposed. They were asked to wear TLDs on their fingertips, to evaluate the quantity Hp(0.07) to the skin and to replace them after each labelling and administration procedure.Data collected from 2009 to 2014 were divided into two groups: before introducing ADD (NoADD) and after introducing ADD (ADD), considering 52 procedures (177Lu) , 41 (90Y) in NoADD; 67 (177Lu) and 48 (90Y) in ADD. The mean handled activity: 23.57GBq(177Lu) and 14.31GBq(90Y) in NoADD, 30.11Gq(177Lu), 15.11GBq(90Y) in ADD.Though ADD affects only chemist work, it was considered the same division even for medical staff doses, feeling confident to identify a learning curve.Data were analysed with simple statistical tests (t-test and Wilcoxon-Mann-Whitney, p=0.05) and shown separately for chemist and physician.Results: For the chemist, Hp(0.07) mean values (95% percentile) for ADD and NoADD are 0.019(0.076) and 0.030(0.099) mSv/GBq respectively for 90Y, while 0.007(0.023) and 0.022(0.037) mSv/GBq respectively for 177Lu. T-test provided P<<0.05 for both isotopes.The relative differences before and after ADD collected for every finger and considered separately for each isotope were treated with Wilcoxon test. P-value<0.05 .For the medical staff, Hp(0.07) mean values (95% percentile) for ADD and NoADD are 0.0143(0.0565) and 0.021(0.0762) mSv/GBq respectively for 90Y, while 0.0009(0.00263) and 0.0011(0.00196) mSv/GBq respectively for 177Lu. T-test provided P<0.05 for both isotopes.The relative differences before and after ADD collected for every finger and considered separately for each isotope were treated with Wilcoxon test. P-value>0.05.ConclusionsADD affects positively the dose saving of the chemist in handling both isotopes and the dose saving depends on the isotope used, when data are analysed finger by finger.For the reason mentioned above, ADD doesn't affect strongly the medical staff dose saving. However, the mean value analysis shows a learning curve of the workers to inferior doses in more recent time. The difference in doses doesn't depend on the isotope used, when data are analysed finger by finger.

Evaluation of nigrostriatal oxidative stress intensity in patients with Parkinson's disease using [Cu-62]ATSM PET and FP-CIT SPECT

H. Okazawa[1], M. Ikawa[1], T. Tsujikawa[1], T. Mori[1], A. Makino[1], Y. Kiyono[1], M. Yoneda[2]; [1]University of Fukui, FUKUI, JAPAN, [2]Fukui Prefectural University, FUKUI, JAPAN.

Introduction: To evaluate degree of oxidative stress and mitochondrial dysfunction in the nigrostriatal dopaminergic neurons of Parkinson's disease (PD), positron emission tomography (PET) with [Cu-62]diacetyl-bis(N4-methylthiosemicarbazone) (Cu-ATSM) and dopamine transporter (DaT) imaging were applied to patients with PD. Methods: Nine patients with PD (69 ± 5y) who showed lateral dominant symptoms at onset underwent Cu-ATSM PET. They also underwent [I-123]FP-CIT SPECT to evaluate presynaptic nigrostriatal dopaminergic deficit as well as DaT density. Dynamic PET data acquisition was performed, and standardized uptake value (SUV) images were calculated from the delayed phase data of 10-20 min frames after the injection. Multiple circular regions of interest (ROIs) were drawn on the bilateral striata and mean values from each side were used for analysis. The striatum-to-cerebellum SUV ratio (SCR) was calculated from the SUVs of the striatum and the cerebellar cortex. The same striatal ROIs were applied to the [I-123]FP-CIT SPECT images and distribution volume ratio (DVR) was calculated. Finally, SCR to DVR ratio (SDR) were obtained and used for further analysis. Results: The means of SCR, DVR and SDR of the bilateral striata in patients were 1.04 ± 0.04, 1.20 ± 0.08 and 0.88 ± 0.05, respectively. The mean values of the striatum contralateral to the initially affected body side (the dominant striatum) were lower in DVR and greater in SCR and SDR compared to the contralateral side. Although the difference in SCR was not significant, DVR and SDR showed significant difference between the bilateral striata ($P < 0.05$). The SDR of the dominant striatum showed a positive correlation with the Unified Parkinson's Disease Rating Scale (UPDRS) rating ($r = 0.67$, $P < 0.05$), indicating oxidative stress increased according to the progression of disease severity in the dominant striatum. Conclusions: Degree of oxidative stress calculated from accumulation ratios of Cu-ATSM to [I-123]FP-CIT in PD patients revealed that the dominant striatum suffered from intense oxidative stress which correlated well with the severity of symptoms. These findings indicates that oxidative stress associates with striatal neurodegeneration in PD.

OP642

FDG-PET/CT in presymptomatic and symptomatic Huntington's disease: Possible predictor of disease progression?

D. Lopez[1], V. Camacho[1], A. Fernandez[1], J. Perez Perez[2], S. Martinez-Horta[2], F. Sampedro[3], C. Achury[1], R. Jaller[1], A. Montes[1], I. Carrió[1]; [1]Nuclear Medicine department. Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN, [2]Neurology department. Movement Disorder Unit. Hospital de la Santa Creu i Sant Pau, Barcelona, SPAIN, [3]Universitat Autonoma de Barcelona, Barcelona, SPAIN.

PURPOSE: To assess metabolic changes in cerebral 18F-FDG PET/CT in presymptomatic (preHD) and symptomatic (sHD) Huntington's disease (HD) patients, to assess patterns of FDG uptake, and to correlate PET/CT findings with clinical evolution. MATERIALS AND METHODS: Thirty three patients (8 male, mean age=44, range [26-69]) carrying the HD mutation (mean CAG=43) were prospectively included. Based on the Unified Huntington's Disease Rating Scale (UHDRS) motor score and Total Functional Capacity, patients were classified as presymptomatic (preEH=16; UHDRS <4) and symptomatic (sEH=17; UHDRS>4). Subsequently, preHD patients based on Langbehn formula were classified as near (preHD-A=8) and far (preHD-B=8) to onset of clinical manifestations. A separate group of 18 healthy subjects, matched with patients by age and gender, was used as control (4 male, mean age=48 [32-69]). Brain PET/CT was performed 60 minutes after i.v. injection of 277 MBq of 18-FDG on a Philips Gemini TF. Images were initially assessed by 2 nuclear medicine physicians identifying qualitative metabolic changes in the striatum and cerebral cortex. Analysis and quantitative assessment of regional cerebral activity was performed using the Statistical Parametric Mapping (SPM8). For the regional quantitative analysis, the clusters of interest were extracted and computed to the relative standard uptake value (SUVr) of the regions of interest related to the stage of the disease. RESULTS: In the visual analysis, sHD patients presented a significant hypometabolism in striatum compared to preHD patients and controls. Quantitative analysis demonstrated a significant striatal hypometabolism in sHD respect to preHD-A and preHD-B [$p<0.05$ (FWE), EVTk=100 voxels]. Additionally, a significant decrease in metabolism of striatum in both preHD groups respect to GC was demosnstrated, showing a hypometabolic pattern in striatum that progressively declines across disease stages [$p<0.001$ uncorrected, k=10 voxels]. In addition, a significant hypermetabolism in the sHD patients was shown in the prefrontal cortex and cerebellum [$p<0.001$ uncorrected EVTk=10 voxels]. CONCLUSION: HD patients presented a significant progressive hypometabolism in striatum across the disease stages compared to controls. sHD presented a marked hypometabolism with respect to preHD. In sHD patients, a significant hypermetabolism in prefrontal cortex and cerebellum was seen probably related with movement disorder. FDG-PET/CT seems to be an early predictor for disease progression in HD.

Frequency of ^{123}I FP-CIT image characteristics differ between movement disorder and Lewy Body dementia referrals

A. Nicol[1], R. Jampana[2], C. Santosh[2], M. T. Hansen[2]; [1]South Glasgow University Hospital, Glasgow, UNITED KINGDOM, [2]Institute of Neurological Sciences, South Glasgow University Hospital, Glasgow, UNITED KINGDOM.

^{123}I FP-CI T imaging is used to evaluate the loss of functional dopaminergic neuron terminals in the striatum of patients with movement disorders (including Parkinson's disease, essential tremor, drug induced tremor) or Lewy Body dementia. The frequency of ^{123}I FP-CIT image characteristic appearances for the different referral groups will be assessed. Consecutive patients over a four month period were included (n=179). Scanning was performed on a Mediso four head scanner approximately three hours after administration of 185MBq ^{123}I FP-CIT. Referrals were divided into three categories: movement disorders, Lewy Body Dementia (DLB), clinical information including a mixture of these two categories. Scans were evaluated visually, using striatal:occipital ratio quantification as an adjunct as required. Images were categorised as follows: (a) normal (b) reduced uptake:putamen < caudate (c) balanced reduced uptake (weak comma) or (d) other (none of above). Clinical referrals were received for movement disorders in 151 of cases (84%), DLB in 17 cases (10%) and mixed referral information in 11 cases (6%). Normal image appearances were obtained in 54% of movement disorder referrals, 53% of DLB referrals and 73% of mixed clinical referrals. Of the abnormal scans, reduced uptake: putamen < caudate & balanced reduced uptake (weak comma) appearances were obtained in 38% & 3% of movement disorder referrals; 12% & 29% of DLB referrals and 0% & 9% of mixed referrals. 'Other' appearances, dominated by the presence of vascular components, occurred in 5% of movement disorder referrals, 6% of DLB referrals and 18% of mixed referral information . A chi squared test of homogeneity was performed for the movement disorders and Lewy Body Dementia referrals (n=168). This rejected the null hypothesis that the frequency of normal : putamen < caudate : balanced reduced uptake (weak comma) appearances was identical in these two patient referral groups ($p<0.01$) These results indicate that the frequency of ^{123}I FP-CIT image characteristics differ between movement disorders and Lewy Body Dementia referrals. This is critically important when clinically evaluating scans.

OP644

[11C]Donepezil PET demonstrates parasympathetic denervation in the gut of most patients with de novo Parkinson's disease (PD).

T. Fedorova[1], L. Seidelin[1], S. Jakobsen[1], E. H. Danielsen[2], D. J. Brooks[1], **P. Borghammer**[1]; [1]Department of Nuclear Medicine & PET Centre, Aarhus University Hospital, Aarhus C, DENMARK, [2]Department of Neurology, Aarhus University Hospital, Aarhus C, DENMARK.

Background: We recently demonstrated that most PD patients at a moderate disease stage display decreased [11C]donepezil PET signal in the small intestine, and 2/3 of patients displayed a similar decrease in the pancreas (Gjerløff et al, Brain 2015). It is thought that parasympathetic denervation may predate motor symptoms in PD, and parasympathetic PET imaging may therefore be a potential diagnostic marker at pre-motor stages of the disease. Objective: We used the acetylcholinesterase PET ligand [11C]donepezil to estimate the peripheral parasympathetic innervation in de novo PD. Methods: So far 17 PD patients at an early disease-stage (mean 1 year disease duration) and 10 matched control subjects were enrolled. All study participants were PET/CT scanned using [11C]donepezil. The PET signal in the myocardium, gastrointestinal tract, and pancreas was compared between groups. Results: The de novo PD patients displayed significantly decreased [11C]donepezil SUV values in the small intestine (-24%, $p<0.0001$), but not in the pancreas ($p=0.75$). A trend towards decreased signal was seen in the myocardium (-11%, $p=0.07$). Conclusions: The data implies that marked parasympathetic denervation in the gut of PD patients is established already at the time of diagnosis, whereas pancreatic denervation may be a secondary phenomenon. [11C]donepezil PET could therefore have application as a diagnostic marker in PD - maybe already at the pre-motor stage. We are currently initiating a longitudinal [11C]donepezil PET study of pro-dromal PD patients with REM sleep disorder to test this hypothesis

Brain metabolic changes in patients with Essential Tremor and progressive gait ataxia under thalamic deep brain stimulation

J. Brumberg[1], G. Marotta[2], M. Reich[3], F. Steigerwald[3], N. Pozzi[3], C. Lapa[1], S. Samnick[1], K. Herrmann[1], J. Volkmann[3], A. Buck[1], I. Isaias[3]; [1]Department of Nuclear Medicine, University Hospital Würzburg, Würzburg, GERMANY, [2]Department of Nuclear Medicine, Fondazione IRCCS Ca Granda - Ospedale Maggiore Policlinico, Milano, ITALY, [3]Department of Neurology, University Hospital Würzburg, Würzburg, GERMANY.

AIM: We investigated brain metabolic changes under different deep brain stimulation (DBS) parameters in patients with Essential Tremor (ET). We aimed to disentangle the effect of thalamic stimulation from disease progression in the evolution of gait- or limb-ataxia. MATERIALS AND METHODS: We investigated five subjects with ET (two males; median age: 74 years, range: 63-84 years) under stable bilateral thalamic DBS (no stimulation changes in the last four weeks) with progressive and severe gait-ataxia (unable to walk unassisted) by means of 18F-fluorodeoxyglucose (FDG) and two sequential cerebral positron emission tomographies (PET). PET scans were conducted stim-on and 72h after stimulation holidays (stim-off) according to a standardized protocol. Patients were fully relaxed in a lying position without any voluntary movement between the FDG injection and the scan. We performed a statistical parametric mapping voxel-by-voxel group comparison (stim-on vs. -off) applying the proportional global mean, threshold at $p<0.1$ and corrected for Family wise-error (FWE). RESULTS: At 72h stim-off, gait ataxia improved in all subjects (all were able to walk unassisted), whereas tremor reappeared with a pre-surgery severity. Compared to 72h stim-off, FDG uptake in stim-on was significantly increased selectively in the flocculonodular lobe of cerebellum ($T=6.40$, $p<0.01$) and reduced in the right medial frontal and bilateral precentral gyri (right BA 6, $p<0.001$ and left+right BA 4, $p<0.001$). CONCLUSIONS: Multiple PETs can play a relevant role in defining brain metabolic changes in different clinical or therapeutic (e.g. DBS) settings. Our findings are evocative of an antidromic effect of thalamic DBS on outflow pathways of the vestibulocerebellum in patients with ET. Accordingly, in these patients, gait-ataxia might be interpret as a stimulation side effect rather than an additional sign of this disease.

OP646

18F-FDOPA PET reveals a rostro-ventral striatal dopaminergic depletion in Parkinson's disease patients with impulse control disorder.

A. Marí Hualde, E. Prieto, L. Sancho, M. Ribelles, C. Juri, M. Rodríguez-Oroz, J. Obeso, J. Arbizu; Clinica Universidad de Navarra, Pamplona, SPAIN.

Background: Many Parkinson's disease (PD) patients experience non-motor symptomatology. Impulse control disorders (ICDs), including compulsive gambling, buying, sexual behaviour, and eating, is a severe complication difficult to diagnose that can occur in a significant number of PD population (6,1-31,2%). While these abnormal behaviours are associated with dopaminergic treatments, a differential pattern of nigrostriatal dopaminergic denervation has been suggested by findings in DAT-scan. Functional brain differences in PD patients with and without ICD remain poorly understood. Objective: To ascertain the striatal pattern of dopaminergic depletion by L-3,4-Dihydroxy-6-[18F] fluorophenylalanine (18F-FDOPA) Positron Emission Tomography (PET) in PD patients with and without ICD. Methods: 60 PD 18F-FDOPA PET scans were studied (30PD-ICD and 30 PD without a life history for ICD), as well as 16 healthy controls (HC). 12 of the PD-ICD patients had a previous basal 18F-FDOPA PET. Disease severity was ascertained with the UPDRS and the Questionnaire for Impulsive-Compulsive Disorders in PD (QUIP) and Levodopa

equivalent dose (LED) was calculated in each patient. A voxel-based-analysis (SPM) was applied to measure 18F-FDOPA uptake (Ki) between all of them. Results: PD-ICD and PD without ICD, did not differ in age or UPDRS punctuation. All PD patients showed a typical striatal denervation pattern with predominance reduction in 18F-FDOPA uptake in the caudal putamen. 18F-FDOPA uptake was significantly reduced in the anterior and ventral striatum in ICD-PD patients compared to those without ICD ($p<0,01$). But no difference was found between PD previous to ICD symptomatology scan, when compared to 12 PD without life history of ICD paired by age, LEDs and PD progression time. Total LED was higher ($p=0,006$) in ICD-PD patients (mean 957,2) compared to the non- ICD group (mean 501,27). No significant difference was found in the mean dose of dopaminergic agonist LEDs. Conclusions: This study confirms a significant reduction in ventral striatal dopaminergic activity in ICD-PD patients by 18F-FDOPA PET in advanced disease but not in basal conditions. However, the ICD-PD group received higher dose of dopaminergic agents. The interaction between denervation and treatment probably defines the origin of ICD in PD.

OP647

Correletion between 123I-FP-CIT SPECT and cognitive outcome in Parkinson's disease: 5 years of follow-up

G. Puccini[1], R. Ceravolo[2], F. Guidoccio[1], D. Frosini[2], S. Chiacchio[1], M. Gennaro[1], U. Bonuccelli[2], D. Volterrani[1]; [1]Regional Center of Nuclear Medicine, University of Pisa, PISA, ITALY, [2]Neurology Unit, Department of Clinical and Experimental Medicine, University of Pisa, PISA, ITALY.

Aim: Dopamine transporter (DAT) imaging is a common diagnostic tool for Parkinson's Disease (PD) but also evaluated as prognostic marker for both motor and non motor outcomes. The ability of coping an intersecting pentagons is considered an important clinical predictors of global cognitive decline. In this study we evaluated the prognostic role of DAT imaging and pentagon copy for cognitive outcome in a cohort of PD patients with a follow up of five years. Materials and methods: Ninety-five de novo PD patients underwent DAT imaging at baseline. Striatal semiquantitative indices were calculated with basal ganglia matching tool. All the patients were assessed with Unified Parkinson's Disease Rating Scale (UPDRS) part III for motor related impairment and Mini-Mental State Examination (MMSE) for cognitive functions at baseline and each year of the five years of follow up. The occurrence of dementia in the five years of follow up was collected. According with MMSE and pentagon test score we further divided the subjects into two sub-groups. Results: During follow up 18% of patients developed dementia. Patients developing dementia in the follow up period had lower striatal binding at baseline ($p<0.01$). The frequency of impairment in pentagon copy was significantly higher in PD patients developing dementia ($\chi2=9.9$, $p<0.001$). Rather not statistically significant, patients developing dementia showed higher level of motor impairment (UPDRS III 22 vs 18 respectively for PD with dementia and not developing dementia) and lower MMSE at baseline (MMSE 26 vs 28 respectively for PD developing dementia and not developing dementia). Binary logistic regression analysis was performed dichotomizing striatal uptake value according to striatal median uptake (2.3). The model contained two independent variables (striatal uptake and pentagon copy), the full model was statistically significant ($\chi2=20.7$, $p<0.001$) and as whole was able to predict the 35% of the variance in cognitive status. Both variable independently contribut ed to the model with an Odd Ratio respectively of 15.9 and 4.9 for low striatal baseline uptake and pentagon copy impairment. Conclusion: Our findings show that DAT imaging performed at baseline and visuospatial and constructional ability as evaluated by pentagon copy intersection performance are associated with cognitive outcome in PD patients. Multiple variables have been associated to the risk of dementia in PD. In line with previous findings our data confirm that the integration of dopaminergic deficit and the dysfunction of cortical posterior area are associated with the risk of cognitive impairment.

OP648

Initial Evaluation of [18F]GE-180 PET Imaging in Relapsing-Remitting Multiple Sclerosis Patients

S. Sridharan[1], C. Buckley[2], W. Trigg[2], W. Trigg[2], K. Heurling[2], P. Sherwin[2], D. Brooks[2], J. Crouch[3], J. Crouch[3], M. Lawler[3], R. Hinz[1], R. Paulseth[3], S. Amodeo[3], K. Gulenchyn[3]; [1]University of Manchester, Manchester, UNITED KINGDOM, [2]GE Healthcare, Amersham, UNITED KINGDOM, [3]St. Joseph's Hospital, Hamilton Health Sciences, Hamilton, ON, CANADA.

Introduction: Multiple sclerosis (MS) is characterised by demyelination, but it is known from pathology studies that inflammation, evidenced by infiltrating immune cells and activated microglia in normal appearing white matter (NAWM), is also present at different disease stages. The effects of inflammation on MS progression are not yet understood; positron emission tomography (PET) offers the opportunity to monitor these effects and thus aid patient stratification and guide therapy selection, adding to the information already available from MRI techniques.The 18 kDa translocator protein (TSPO) is upregulated in activated microglia, which are present in inflammatory lesions and NAWM in MS. [^{11}C]-(R)-PK11195 is a TSPO-PET ligand which is known to show localisation and extent of inflammation in many brain diseases, including MS[1], but suffers from a

poor signal to noise ratio (SNR) and short (20 minutes) half-life. [18F]GE-180 is a novel TSPO-PET ligand which has shown improved SNR and lower non-specific binding than [^{11}C]-(R)-PK11195 in pre-clinical models[2]. Here, we present initial results from a phase 1 study in relapsing-remitting MS (rrMS) and healthy control subjects (HVs).Methods: HVs and rrMS subjects were assessed for binding status. One non-binder in each group was included. Subjects underwent T1 pre and post gadolinium enhanced MRI scans and T2 scans additionally. 90 minute dynamic [18F]GE-180 PET scans were performed typically within 1 month. PET and T1 pre-contrast MR images were co-registered in the software package PMOD, and the Hammers atlas[3] was applied to acquire standardised uptake values (SUVs) for regions of interest (ROIs). Selected areas of T2 hyperintensity were defined manually to give MS lesion SUVs. A cortical composite grey matter (GM) region was chosen as reference for SUVRs.Results: No Gd-enhancing lesions were identifiable from T1 post-contrast MRIs. With [18F]GE-180, whole WM uptake (SUVRGM) was slightly higher in rrMS than HVs, while a lesion-rich periventricular (PV) area yielded SUVRs which were approximately 10% higher in rrMS than HVs. PET-defined lesions in rrMS showed an elevation of 20 - 40% compared to HVs.Conclusion: Preliminary results suggest that [18F]GE-180 is able to identify areas of inflammation in PET images which are non-Gd-enhancing in T1.[1] Rissanen, E. et al. 2014, J. Nucl. Med., 55: 1-6[2] Boutin, H et al. 2015, Eur. J. Nucl. Med. Mol. Imaging, 42: 503-511[3] Hammers, A. et al. 2002, Hum. Brain Mapp., 15: 165-174.

18F-5-FPN, a Novel PET Imaging Probe Targeting Malignant Melanoma

X. Lan, H. Feng, X. Xia, Y. Song, C. Qin, Q. Liu, Y. Zhang; Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.

Aim: Melanoma is one of the most aggressive skin cancers, and early diagnosis and accurate staging are important for planning therapeutic intervention to improve patient outcomes. Radiolabeled benzamides (BZAs) are attractive candidates for targeting melanoma because they bind to melanin and exhibit high tumor uptake and retention. In this study, we synthesized a BZA analog, 5-bromo-N-(2-[diethylamino]ethyl) picolinamide, labeled it with 18F, and named it 18F-5-FPN. We evaluated its binding affinity to, and specificity for, melanin, and its in vivo pharmacokinetics, to assess its potential value in diagnosing and staging melanoma. Methods: (N-[2-Diethylamino] ethyl)-5-fluoropicolinamide and its bromo- precursors were prepared, and radiofluorination of 18F-5-FPN with a radio-synthesis module (GE TraceLab FXFN GE Healthcare, Milwaukee, WI, USA) was performed and purified. Its binding specificity was measured in vitro in two different melanoma cell lines, one pigmented (B16F10 cells) and one nonpigmented (A375m cells), and in vivo in mice xenografted with the same cell lines. Dynamic and static positron-emission tomography (PET) images using 18F-5-FPN were obtained in the tumor mice, and the static images were compared with those acquired with 18F-fluorodeoxyglucose (18F-FDG). Lung metastases mice bearing B16F10 tumor were also performed PET imaging with 18F-5-FPN. Results: 18F-5-FPN was successfully prepared with radiochemical yields of 5%-8%. Cellular uptake study revealed that binding of 18F-5-FPN to B16F10 cells was much higher than that to A375m cells. Dynamic PET images showed that B16F10 tumor could be seen about 1 min after injection of the tracer, and the uptake gradually increased over time. 18F-5-FPN was rapidly excreted by the kidneys. Static images acquired 1 and 2 h after injection revealed clearly visible B16F10 tumors, with high uptake values of 24.34 ± 6.32 and 16.63 ± 5.41 % ID/g (n=5) in the biodistribution study, and tumor-to-muscle and tumor-to-blood ratios reached to 43.90 ± 9.09 and 65.52 ± 10.76 at 2 h, respectively. In contrast, there was no visible uptake by the A375m tumors. 18F-5-FPN and 18F-FDG PET imaging were compared in B16F10 tumor xenografts, and the tumor-to-background ratio of 18F-5-FPN images were 10 times higher that of 18F-FDG (35.22 ± 7.02 vs 3.29 ± 0.53, n=5). 18F-5-FPN PET imaging also detected simulated lung metastases measuring 1-2 mm. Conclusions: 18F-5-FPN specifically targeted melanin in vitro and in vivo with higher retention, affinity and favorable pharmacokinetics. 18F-5-FPN may be an ideal molecular probe for melanoma diagnosis and staging. This work was supported by NSFC 81371626.

PW002

PET imaging of a feeding center using [11C]BU99008 with ultra-high specific activity

K. Kawamura[1], Y. Shimoda[1], J. Yui[1], Y. Zhang[1], T. Yamasaki[1], H. Wakizaka[1], M. Fujinaga[1], K. Kumata[1], L. Xie[1], A. Hatori[1], M. Ogawa[1,2], Y. Kurihara[1,2], N. Nengaki[1,2], M. Zhang[1]; [1]National Institute of Radiological Sciences, Chiba, JAPAN, [2]SHI Accelerator Service, Tokyo, JAPAN.

Aim: I2-imidazoline receptor (I2R) is involved in various central nervous systems disorders, but function associated with I2R is unknown. I2R was found throughout the brain, particularly in the arcuate nucleus of hypothalamus with a high density [1]. Nutt et al. previously reported that selective I2R ligands promoted food intake [2], which is presumed to be an effect of eating function through the arcuate nucleus of the hypothalamus known as a feeding center. We recently reported that [^{11}C]FTIMD with ultra-high specific activity (SA; mean 4470 GBq/μmol) for imaging of I2R showed higher specific binding than [^{11}C]FTIMD with conventional SA (about 100 GBq/μmol) in the hypothalamus. More recently, Kealey et al. developed [^{11}C]BU99008 as a more potent PET ligand for I2R imaging [4]. [^{11}C]BU99008 displayed a relatively high brain penetration and specific binding in the porcine and rhesus brain [4,5]. In this study, to image the feeding center, we evaluated the usefulness of PET study using [^{11}C]BU99008 with ultra-high SA. Materials and methods: [^{11}C]BU99008 was prepared by methylation of the BU-precursor and [^{11}C]methyl iodide, which was produced by iodination of [^{11}C]methane using the single-pass method [6]. Brain PET studies were conducted in SD rats and Zucker fatty rats. Results: [^{11}C]BU99008 with ultra-high SA were successfully synthesized in the range of SA at 5400~16600 GBq/μmol (n = 7) at the end of synthesis. In SD and Zucker fatty rats, the radioactivity after injection of [^{11}C]BU99008 with ultra-high SA was highly accumulated in the hypothalamus. Pretreatment with BU224 (a high affinity I2R ligand, 1 mg/kg) significantly decreased the radioactivity (AUC30-60 min) in the hypothalamus to 86% of control radioactivity. Conclusion: [^{11}C]BU99008 with ultra-high SA showed high specific binding in rat brain. PET study using [^{11}C]BU99008 with ultra-high SA would contribute to in vivo imaging of the eating function with small change.References: [1] Lione LA, et al. Eur J Pharmacol. 1998;353:123-35. Radiosynthesis of a [^{18}F]-quinuclidine 1,2,3-triazole derivative as PET radioligand for neuroimaging of the α7-nicotinic acetylcholine receptor

J. Sarasamkan[1,2], S. Fischer[1], M. Scheunemann[1], P. Brust[1], O. Vajracupta[2]; [1]Helmholz-Zentrum Dresden-Rossendorf, Leipzig, GERMANY, [2]Mahidol University, Bangkok, THAILAND.

Aim: The α7-nicotinic acetylcholine receptor (α7-nAChR) is well recognized as a key receptor involved in memory formation and cognition which implicates its involvement in the pathophysiology of neurodegenerative disorders. Currently, this receptor subtype is one of the most attractive targets for neuroimaging to monitor the etiology and progression of brain diseases such as schizophrenia and Alzheimer's disease (AD). Therefore, a new positron emission tomography (PET) radioligand selective to α7-nAChR was developed in this study. The structure of the developed ligand is based on a novel potent and selective α7-nAChR agonist, 3-(4-hydroxyphenyl-1,2,3-triazol-1-yl) quinuclidine (QND8) which demonstrated cognitive enhancement in mice. Materials and methods: The structure of the radioligand (^{18}F-QND) was modified from QND8 by replacing the hydroxyl group with fluorine. After synthesis of the starting quinuclidine azide and aryl alkyne, F-QND and its precursor were synthesized by copper-catalyzed azide-alkyne cycloaddition (CuAAC) or click chemistry. Their structures were confirmed by ^{1}H-NMR, ^{13}C-NMR and mass spectrometry (MS). ^{18}F-QND was radiolabeled by nucleophilic substitution of the nitro precursor. Altered amounts of kryptofix and various conditions (solvent and temperature) were chosen to improve the radiolabeling yield. The radiolabeled compound was separated and purified by chromatography. The radiochemical yield and radiochemical purity were analyzed by radio-thin layer chromatography and radio-high performance liquid chromatography. Non-radioactive references were used to confirm the stereochemistry of the nitro-precursor and F-QND. Results: The chemical yields of the nitro-precursor (NO_2-QND) and the reference standard (F-QND) were 21% and 11%, respectively, with purity higher than 95%. The radiolabeling yield of ^{18}F-QND was 7% with radiochemical purity > 98% and specific activity of 65 GBq/μmol. The stereochemistry study approved that both compounds were optically active. Therefore, the developed radiochemical processes can be applied for the radiosynthesis of further ^{18}F-QND-derivatives. Conclusion: Radiosynthesis of ^{18}F-QND was accomplished by nucleophilic substitution of the phenyl-nitro compound. However, at high temperature partial racemization cannot be excluded.

PW004

[11C]Me@HAPTHI - A Novel PET-ligand for the Norepinephrine Transporter: Target Affinity and Radiosynthesis

C. Rami-Mark[1], N. Berroteran-Infante[1], A. Hoepping[2], M. Hacker[1], M. Mitterhauser[1], **W. Wadsak**[1]; [1]Medical University of Vienna, Vienna, AUSTRIA, [2]ABX - Advanced Biochemical Compounds, Radeberg, GERMANY.

The norepinephrine transporter (NET) has been demonstrated to be relevant to a multitude of neuropsychiatric and cardiovascular pathologies. Due to the wide range of possible applications for PET imaging of the NET together with the limitations of currently available radioligands, novel NET-PET tracers are seriously needed.METHODS:Precursor, HAPTHI ((S)-1-(4-amino-3-hydroxybutyl)-3-phenyl-1,3-dihydrobenzo[c] [1,2,5]thiadiazole-2,2-dioxide), and reference compound, Me@HAPTHI ((S)-1-(3-hydroxy-4-(methylamino)butyl)-3-phenyl-1,3-dihydrobenzo[c][1,2,5]thiadiazole 2,2-dioxide), were custom-synthesized by ABX.For optimization of radiosynthesis conditions, small-scale reactions (<2GBq) were performed. The influence of various reaction conditions, i.e. reaction temperature, solvent and base, precursor concentration and radiomethylation agent, was investigated. The automation of the N-^{11}C-methylation reaction was done on a TRACERlab FX C Pro synthesizer (GE Healthcare).The affinity of new radiolabeled ligand was determined in a NET-expressing membrane binding protocol.RESULTS:In the radiochemical evaluation, best results were obtained with sodium hydroxide catalysis in 2-butanone(MEK) as solvent for 2min at 75°C using 2mg/mL precursor HAPTHI. Thereby, 54.0 ± 8.3% radiochemical incorporation yield was achieved. These optimum reaction parameters were subsequently used in the fully automated radiosynthesizer. So far, 9 large-scale radiosyntheses were performed, yielding 1.5 ± 0.5GBq (10.9 ± 4.9%, corrected for decay) of sterile, formulated [^{11}C]Me@HAPTHI within 36min. A mean specific activity of 71.4 ± 26.3 GBq/μmol was found. Full radiopharmaceutical quality control took 5min and showed that radiochemical purity always exceeded 98%.Affinity of reference compounds, Me@HAPTHI, using human NET membranes evinced a Kd of 0.21 ± 0.07nM (n=9). For determination of selectivity, additionally the affinity towards human DAT and SERT membranes were measured and revealed >10μM for DAT and 409 ± 43nM for SERT, respectively, (n=5). Hence, selectivity of Me@HAPTHI

towards NET was determined as DAT/NET>1947.6 and SERT/NET=9757. CONCLUSION: This study confirms an outstanding affinity and selectivity of the title compound towards human NET as well as its feasible radiochemical preparation for further preclincal evaluations ans future in-vivo applications.

PW005

Bringing radiotracing to titanium-based antineoplastics: automated synthesis, PET and ex-vivo evaluation of [45Ti](salan)Ti-derivatives

F. Zhuravlev; G. W. Severin, C.H. Nielsen, J. Fonslet, A. Ingemann, A. Kjaer,Hevesy Laboratory, Roskilde, DENMARK.

Introduction: Recent advances in titanium-stabilizing ligands have led to a new class of cytotoxic Ti-based antineoplastics. Implementation of ^{45}Ti PET (^{45}Ti: 85% positron branch, 3.1 h half-life) and radiotracing early in preclinical development could aid in determining the mechanism of action, and evaluate dosing and drug formulation. Aim: We aimed at developing a novel solid-phase based ^{45}Ti radiolabeling methodology and the implementation of ^{45}Ti-PET in titanium-based antineoplastics using hydrolytically stable [^{45}Ti](salan)Ti compounds. This development was intended to allow elucidation of the biodistribution and pharmacokinetics of promising new Ti-based therapeutics. Materials and Methods: ^{45}Ti was produced by the ^{45}Sc(p,n)^{45}Ti reaction and recovered on HypoGel 200 diol resin. A series of [^{45}Ti](salan)Ti(dipic) derivatives was synthesized by on-column complexation of resin-bound ^{45}Ti with the corresponding ligands. HPLC/radioHPLC and TLC/radio-TLC were used to confirm the identity of the radioproducts. Imaging and biodistribution studies of the parent [^{45}Ti](salan)Ti(dipic) were carried out with NMRI nude mice bearing dual-flank HT-29 xenograft tumors using intravenous (iv) and intraperitoneal (ip) injections. For the iv injection, dynamic PET data were obtained for 1h following injection. The ip injections were followed by static PET scans at 1 and 7h pi and conventional ex-vivo biodistribution studies. Results: ^{45}Ti was isolated from bulk scandium on HypoGel 200 column with 93 ± 3% recovery. The introduction of salan and dipic were performed by passing the solutions of ligands in pyridine sequentially through the HypoGel 200 column at 25oC and 100oC correspondingly giving chemically and radiochemically pure products in overall 10-20% RCY. The dynamic ^{45}Ti PET performed after iv injection demonstrated rapid (3.8 min) blood clearance. The ip injections demonstrated the biliary excretion and negligible tumor accumulation. However ex vivo biodistribution, gave a quantifiable signal in the tumors with concentration estimated at 257 pmol/g. Conclusion: The automated solid-phase radiosynthesis of [^{45}Ti](salan)Ti(dipic) derivatives was efficient and is expected to be applicable to a broad range of supporting and terminal ligands. ^{45}Ti PET and radiotracing allowed elucidation of the in vivo behavior of promising titanium compounds encouraging its adoption as a tool in Ti theranostics.

PW006

[11C]Me@HAPTHI - A Novel PET-ligand for the Norepinephrine Transporter: Preclinical Evaluation

C. Rami-Mark[1], W. Wadsak[1], C. Philippe[1], C. Vraka[1], A. Hoepping[2], M. Hacker[1], **M. Mitterhauser**[1]; [1]Medical University of Vienna, Vienna, AUSTRIA, [2]ABX - Advanced Biochemical Compounds, Radeberg, GERMANY.

The norepinephrine transporter (NET) has been demonstrated to be pivotal in many neuro-psychiatric and cardiovascular pathologies. [^{11}C]Me@HAPTHI, a novel potential NET-PET tracer, was shown to have a high target affinity and selectivity. Hence, further in vitro evaluation regarding blood-brain-barrier (BBB) penetration, stability and binding properties in autoradiography on different tissues is required. METHODS: LogD was assessed using HPLC (Donovan & Pescatore J Chrom A, 2002). Immobilized artificial membrane (IAM) chromatography was performed using a standard method (Vraka C et al. EJNMMI, 2014) to achieve Pm (permeability) values.For evaluation of stability, incubation with human liver microsomes was performed. Plasma protein binding was determined quantifying the free fraction (ff) in human pooled plasma (Huang Y et al. J Cereb Blood Flow Metab, 2002).In vitro autoradiography was performed on human brain tissue (cortex, thalamus, hippocampus, cerebellum, and hypothalamus) as well as rat heart. Non-specific binding was determined with excess Nisoxetine (10μM). For competition, non-radioactive FMeNER-D2 and Me@HAPTHI were added. After 1h at room temperature, incubation was stopped and slices were processed on phosphor imaging films. Post-autoradiographic processing of the slices was done by Nissl staining in order to facilitate morphological mapping. Immunohistochemical (IHC) staining experiments were performed on rat and human tissue cryo-slices, vicinal to the slices used for autoradiography.RESULTS:Excellent affinity (KD = 0.21±0.07nM) and selectivity (DAT/NET>1940; SERT/NET=9700) were already shown for [^{11}C]Me@HAPTHI. Both logD (2.27±0.01) and Pm

(1.15±0.25) were found to be in a range for expectable BBB penetration. After 60min incubation with human liver microsomes, 99.6±0.3% of the tracer were still intact. ff was found to be 8.2±0.3%.In the autoradiographic experiments, highest uptake of [^{11}C]Me@HAPTHI was observed in NET-rich regions identified with IHC and a concentration dependent binding displacement was seen for both competitors. CONCLUSION: Besides its high affinity & selectivity, we now demonstrated [^{11}C]Me@HAPTHI's stability, expectable BBB penetration and specific binding in autoradiography. This encourages us for in vivo application in small animal PET experiments and future clinical trials.

PW007

Preparation of 6-[18F]Anle138b: a novel PET-tracer potentially suitable for imaging of neurodegenerative and prion diseases

F. Zarrad[1,2], B. D. Zlatopolskiy[2], B. Neumaier[1,2]; [1]Institute of Neuroscience and Medicine, Nuclear chemistry (INM-5), Forschungszentrum Jülich, Jülich, Jülich, GERMANY, [2]Institute of Radiochemistry and Experimental Molecular Imaging, University Clinic Cologne, Cologne, GERMANY.

Objective: Anle138b is a novel compound that binds selectively to the deposits of aggregated proteins found in neurodegenerative diseases like Parkinson's and Alzheimer's as well as in prion disease. This work aim to prepare a 18F-labeled analog of Anle138b using 1,3-dipolar cycloaddition between the radiofluorinated phenyldiazomethane generated in situ and the appropriate terminal alkyne.Method:As a prototype reaction 1,3-dipolar cycloaddition between 4-[18F]fluorophenyldiazomethane prepared from the corresponding tosylhydrazone and 4-fluorophenylacetylene was optimized with respect to reaction time and temperature, base and solvent. 6-[18F]Fluoro-3,4-methylendioxybenzylidene tosylhydrazone ([18F]1) was prepared via the reaction of known 6-[18F]fluoropiperonal ([18F]2) with tosylhydrazide. The corresponding 18F-labeled diazomethane was generated in situ by the thermolysis of the salt of [18F]1 in the presence of base. This 1,3-dipole reacted with 3'-bromophenylacetylene to give 6-[18F]Anle138b.Results:4-[18F]Fluorobenzylidene tosylhydrazone was prepared from 18F- in 62% RCY and with 93% RCP via one-pot two-step preparation procedure using SPE purification and allowed to react with 4-fluorophenylacetylene. Under the optimized reaction conditions (LiOtBu in MeCN, 95 °C, 25 min) RCC of the appropriate 18F-labeled 3,5-disubstituted pirazole amounted to 67%. Using the same set of conditions 6-[18F]Anle138b was prepared in RCCs of 27-34%.Conclusion:An efficient method for the regioselective preparation of radiofluorinated 3,5-disubstituted pyrazoles was developed. This procedure allowed to produce 6-[18F]Anle138b, a potential tracer for protein deposition in brain, in activity amounts sufficient for preclinical studies.

Radio-synthesis and biological evaluation in animal models of [^{11}C] 1-(4-Fluorophenil)-3-(2-methoxyethyl) -2-methyl-5-(4-methyl-sulfonyl) phenil)-1*H*-pyrrole (VA 426), a highly selective Cyclooxygenase-2 inhibitor

A. Carpinelli[1], G. Di Grigoli[1], A. Di Capua[2], A. Cappelli[2], M. Biava[3], A. Coliva[4], M. C. Gilardi[1], L. Gianolli[5], M. Anzini[2], R. Moresco[6]; [1]CNR-IBFM, Milan, ITALY, [2]Università di Siena, Siena, ITALY, [3]Università La Sapienza, Rome, ITALY, [4]Università Vita-Saluta S.Raffaele, Milan, ITALY, [5]Ospedale S. Raffaele, Milan, ITALY, [6]Università Bicocca, Milan, ITALY.

Introduction: Cyclooxygenase (COX) enzymes catalyze the conversion of arachidonic acid to prostaglandins. COX-2 is considered an important target for prevention and cancer therapy, due to its major contribution in the inflammatory response and cancer progression. Non-invasive monitoring of COX-2 expression by molecular imaging techniques may provide unique opportunities to obtain information about disease progression and COX-2 potential role in pathogenesis. In this paper 1-(4-fluorophenyl)-3-(2-methoxyethyl)-2-methyl-5-(4-methylsulfonyl)phenyl) 1*H* pyrrole (VA426) has been synthesized and a preliminary in vivo brain and periphery biodistribution in healthy rats was evaluated. Materials and methods: No carrier added [^{11}C]CO_2 was produced via the $^{14}N(p,\alpha)^{11}C$ reaction using IBA Cyclone 18/9 cyclotron and transferred into a Ge Healthcare TracerlabFXc-Pro module where it was catalytically hydrogenated to form [^{11}C]CH_4. Methane was iodinated to form [^{11}C]CH_3I and then transformed in the highly reactive [^{11}C]methyl triflate by an on line flow-through process. [^{11}C]methyl triflate was bubbled into the reactor where 1-3 mg of the precursor [VA425] was dissolved in anhydrous DMSO containing 1-3 mg NaH. The crude mixture was purified by semi-preparative radio HPLC system equipped with a reversed phase column (ACE C18 250x10 mm, 10 micron, CPS). Acetonitrile/ammonium acetate 0.05M pH t.q. (60/40, v/v) was used as the mobile phase and followed by formulation through a tC18 SPE cartridge. Final solution was sterile-filtered (Millex GP, Millipore). CD rats were injected in the tail vein with 9.25 ± 1.25 MBq of [^{11}C]VA4226. At 10, 30, 60

minutes, rats (n=3 for each time point) were sacrificed and blood was collected into a heparinised tube. Plasma was separated by centrifugation and 100 μL of blood and plasma were counted in a gamma-counter (LKB Compugamma CS 1282). Immediately after sacrifice, peripheral tissues and central areas were sampled and washed with cold saline. Tissues where placed in pre-weighed tubes and counted. Radioactivity concentration was calculated as percentage of the injected dose per gram of tissue (% ID/g tissue). Results: Radiochemical yield based on triflate activity was 7 ± 3% n.d.c.. Radiochemical purity was > 99% and specific activity was 2±0.5 Ci/μmol. [^{11}C]VA4226 was progressively taken up and retained in tissues rich in COX-2 such as heart, lungs, kidneys and intestine. In the Central Nervous System [^{11}C]VA426 reached higher distribution in pons, cerebellum and cortex. Conclusion: Preliminary study encouraged us to further validate this tracer by testing it in animal models of cancer and neuroinflammation. Acknowledgements: Supported by FP7/2007-2013, agreement n° HEALTH-F2-2011-278850 (INMiND).

PW009

18F Labeling of a new naphthalene derivative as potential Alzheimer Disease PET imaging agent. Synthesis and preclinical studies.

L. Fernandez-Maza[1], S. Rivera-Marrero[2], M. Balcerzyk[1], I. Fernandez-Gomez[1], A. Parrado-Gallego[1], M. Sablon-Carrazana[2], R. Perez-Perera[2], O. Diaz-Garcia[2], A. Perera-Pintado[3], A. Prats-Capote[3], C. Rodriguez-Tanty[2]; [1]University of Seville, CSIC, Junta de Andalucía, Seville, SPAIN, [2]Centro de Neurociencias (CNEURO), La Habana, CUBA, [3]Centro de Isótopos (CENTIS), La Habana, CUBA.

Introduction: Radiotracers for β-amyloid plaques PET imaging with best results include naphthalene derivative structures. CNEURO has developed and patented some naphthalene derivative molecules for the diagnosis of Alzheimer Disease at early stages (CU/P/2009/57, CU/P/2013/27, EP 2 436 666 A20, South Africa P58243ZA00. A successful 18F-labelling of such molecules by nucleophilic substitution synthesis was developed at CNA, for β-amyloid plaques PET imaging. Matherial and methods: 3-(6-methoxy-2-naphtyl)propyl-4-methylbenzenesulphonate was used as precursor for the labelling process. 18F- was obtained from a Cyclone 18/9 MeV cyclotron (IBA, Belgium) and nucleophilic substitution took place in a modified TracerLab FXFN module (GE, USA). Azeotropic distillation was performed at 100°C in vacuum and with helium flushing. Fluorination of precursor took place at 70°C for ten minutes, with subsequent acidic hydrolysis and neutralization using NaOH 1N. The intermediate compound (before hydrolysis) was dried to avoid any presence of acetonitrile (precursor solvent). The radiotracer 2-(3-[18F]fluoropropyl)-6-methoxynaphtalene was purified by solid phase extraction cartridges (SPE), connecting two alumina Sep-Pack and a SCX Sep-Pack to retain unreacted 18F- and cationic impurities. The labeled compound was retained in a C18 Sep-Pack, and eluted in absolute ethanol. The solution of radiotracer was diluted with saline for injection. Quality controls were performed before injection to the animals; pH, absence of particles, and radiochemical purity (RCP). RCP was determined with a Dionex HPLC system and a coupled radiation detector. The stationary phase was a C18 reverse phase analytical column and acetonitrile/water (75/25) as mobile phase. Two transgenic mice APPSwe/PS1dE8 with amyloid plaques and two wild type mice for control were injected with the radiotracer for PET/CT studies. Whole body images of biodistribution were obtained, and kinetic curves of radioactivity at several cerebral regions were performed. Results: Radiochemical yield reached 49,8% (uncorrected decay), and radiochemical purity was higher than 95% in all batches. In vitro stability cromatograms demonstrated that 2-(3-[18F]fluoropropyl)-6-methoxynaphtalene is stable for more than ten hours. Comparison between transgenic and control mice was established by cortex-cerebellum SUVratio (SUVr) curve. Conclusions: Radiosynthesis of 2-(3-[18F]fluoropropyl)-6-methoxynaphtalene by nucleophilic substitution of tosyl group at the precursor gives good radiochemical yields and radiochemical purity higher than 95%, which makes the radiotracer useful for brain β-amyloid PET imaging. Its in vitro stability (more than 10h) allows several patient studies from the same batch. PET/CT studies show that 2-(3-[18F]fluoropropyl)-6-methoxynaphtalene crosses blood brain barrier, with higher brain uptake in transgenic mice, in comparison with control animals.

PW010

Efficient synthesis of [18F]FEDAC, and evaluation of non-clinical safety and stability tests for clinical application.

K. Kawamura[1], M. Ogawa[1,2], M. Takei[1], K. Kumata[1], K. Furutsuka[1,2], T. Yamasaki[1], J. Yui[1], L. Xie[1], A. Hatori[1], Y. Zhang[1], N. Nengaki[1,2], K. Hirano[3], M. R. Zhang[1]; [1]National Institute of Radiological Sciences, Chiba, JAPAN, [2]SHI Accelerator Service, Tokyo, JAPAN, [3]NMP Business Support Company, Chiba, JAPAN.

Aim: [18F]FEDAC has potent binding affinity and selectivity for translocator protein (18 kDa, TSPO) [BMCL

2009;19:1707], high signal for neuroinflammation [JNM 2010;51:1301], and high sensitivity and specificity for fatty liver diseases progression [JH 2012;57:1076]. We had previously synthesized [18F]FEDAC by 18F-fluorethylation with [18F]fluoroethyl bromide at two steps using a modified 18F-labelling synthesizer. In this study, we simplified and improved synthesis of [18F]FEDAC by direct [18F]fluorination using a 18F-labelling synthesizer, and performed non-clinical safety and stability tests for clinical study. Materials and methods: [18F]FEDAC was prepared direct fluorination by heating the tosylate precursor with [18F]F- in DMSO at 110 °C for 15 min. Evaluation experiments were performed for the radiation dose estimate in mice, the extended single-dose toxicity study in rats, and in vitro stability tests in the injection and human liver microsomes. Results: [18F]FEDAC was obtained with sufficient radioactivity and suitable quality for injection in clinical study. The radiochemical yield of [18F]FEDAC using 1 and 5 mg precursor based on 18F- was 13 ± 5% (n = 5) and 35 ± 3% (n = 3), respectively, at end of synthesis (EOS) within 65 min of an overall synthesis time. The estimated effective dose equivalent in human was 0.022 mSv/MBq, which was comparable to [18F]FDG injection (0.019 mSv/MBq). [18F]FEDAC injection was stable for 180 min after EOS (over 99% radiochemical purity). In human liver microsomes, [18F]FEDAC was metabolized gradually by CYPs (4.2% parent at 60 min after incubation). A single-dose toxicity of [18F]FEDAC injection was not observed for 14 days after injection in rats. Conclusion: We successfully synthesized [18F]FEDAC by fluorination of the tosylate-precursor with 18F-. [18F]FEDAC injection will be applicable to a clinical study with PET.

Efficacy of Gated-SPECT in Risk Stratification of Major Adverse Cardiac Events in Patients Over 60 Years with Known or Suspected Coronary Artery Disease Undergoing Noncardiac Surgery

M. Vakhromeeva, F. Chanakhchyan, E. Denisenko-Kankiya, N. Bolomatov; Pirogov National Medical Surgical Center, MOSCOW, RUSSIAN FEDERATION.

AIM: To evaluate the prognostic value of myocardial perfusion imaging with gated-SPECT (MPI/SPECT) in patients over 60 with known or suspected coronary artery disease (CAD) before noncardiac surgery. MATERIALS AND METHODS: Overall 225 patients were studied (average age of 66,1±1,1). Patients were classified into 3 groups according to age: 1) <65 years, 2) 65-74 and 3) >75. The Cardiac Risk Index was used to assess patient cardiac risk and included 6 clinical variables. All of them were referred to "stress/rest" MPI/SPECT using two-detector rotating gamma-camera ("Discovery NM/CT 670", GE) before noncardiac surgery. A 20-segment model of the LV was applied. "Summed stress score" (SSS) was used which reflects reduced perfusion in stress. Normal myocardial perfusion was considered if SSS<4; slightly abnormal: SSS=4-7; moderate and significantly abnormal: SSS≥8. The degree of ischemia was assessed by "summed difference score" (SDS): SDS<2 - no ischemia, SDS=2-7 moderate ischemia and SDS>7 - significant ischemia. RESULTS: 160 (71,1%) were proceeded to noncardiac surgery after MPI/SPECT without any additional cardiac testing. The rest 65 (28,9%) patients weren't allowed to operations due to high risk for major adverse cardiac events (MACE) in peri- and/or postoperative periods. Coronary angiography (CAG) was performed to 48 (73,8%) from them, and 46 (95, 8%) had hemodynamically significant stenosis at least in one coronary artery. Myocardial revascularization (MR) was made to 23 (47,9%) patients (15 patients-stenting, 8 patients-CABG). On the whole, SSS and SDS were statistically higher in patients, whom operations were cancelled (p<0,05). Moreover, SSS and SDS were significantly higher in patients over 75 years old (p<0,05). There was significantly reduction of SSS and SDS (p=0,009) when comparing results of MPI/SPECT before and after MR. Noncardiac surgeries were performed to all patients after MR without any MACE. However from 160 patients, whom noncardiac surgeries were performed directly after MPI/SPECT MACE occurred in 13 (8,1%). Myocardial perfusion analysis showed significantly high rates of SSS (7,77±3,79), SDS (3,38±1,68) in these patients compared with those without MACE (p<0,05). In rest 143 patients without MACE SSS and SDS were below 4 and 2, respectively. CONCLUSIONS: MPI/SPECT is an important tool in prediction of MACE in peri- and/or postoperative periods in patients with known or suspected CAD undergoing noncardiac surgery. It is also a reliable method for screening patients with stable CAD for CAG. CAG with subsequent MR should be considered in SSS>4 and SDS>2 in patients with high cardiac risk.

PW012

Hybrid PET/MR viability imaging compared with metabolism/perfusion pattern in acute myocardial infarction

I. Cho, E. Kong, K. Chun, S. Kwon; Yeungnam University Hospital, Daegu, KOREA, REPUBLIC OF.

Purpose : We evaluated simultaneous FDG and late gadolinium enhanced (LGE) PET/MR viability imaging and compared with

metabolism/perfusion patterns. Materials and Methods : Ten consecutive patients diagnosed with acute myocardial infarction were underwent hybrid FDG/LGE PET/MRI examination and Tc-99m MIBI myocardial perfusion SPECT. According to the 17-segment model, FDG uptake, LGE, and Tc-99m MIBI uptake were visually assessed for each segment. Infarcted segments were divided into transmural LGE (involving >50% wall thickness)and subendocardial LGE (involving <50% wall thickness). Results: In 170 segments, 40(23.5%) were rated as infarction on LGE images in which match, mismatch and reverse-mismatch perfusion/metabolism defects were 13(32.5%), 25(62.5%), and 2(5%)segments, respectively. 13(100%) of the match defects appeared as transmural LGE, 23(92%) of the mismatch defects did as subendocardial LGE. Two revese defects showed transmural LGE. conclusion:Perfusion/Metabolism match and mismatch defects might be well correlated with transmural and subendocardial LGE, respectively.

PW013

Metabolic scintigraphy with radiolabeled fatty acid in prognosis of cardiac resynchronization therapy in patients with dilated cardiomyopathy

Y. B. Lishmanov[1,2], M. O. Gulya[2,1], **K. W. Zavadovsky**[2,1], S. I. Sazonova[2,1], D. I. Lebedev[2], V. S. Skuridin[1], V. D. Fillimonov[1]; [1]National Research Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION, [2]Federal State Budgetary Scientific Institution “Research Institute for Cardiology”, Tomsk, RUSSIAN FEDERATION.

Purpose of the study was to study perfusion and metabolism of the left ventricular (LV) myocardium in patients with idiopathic dilated cardiomyopathy (DCMP) and to identify the scintigraphic predictors of the efficacy of cardiac resynchronization therapy (CRT). Methods. The study comprised 63 patients with DCMP and NYHA class III-IV chronic heart failure. Before CRT, all patients received scintigraphy with 99mTc-MIBI and with 123I-BMIPP for evaluation of myocardial perfusion and metabolism, respectively. Before CRT and twelve months after, all patients underwent echocardiography study to estimate intracardiac hemodynamics. Results. Patients were divided into two groups 6 months after CRT: (1) responders - LV ESV decreased by ≥ 15% (n = 39);(2) non-responders - LV ESV decreased by < 15% (n = 24). Prior to CRT, no statistically significant differences were found between groups in hemodynamic parameters (LVEF, end-diastolic volume, end-systolic volume), intra- and interventricular dyssynchrony. Significant differences were found in the following preoperative scintigraphic parameters: myocardial perfusion defect size and metabolic defect size. Correlation analysis demonstrated the presence of significant association ($r = -0.37$, $p < 0.5$) between the sizes of metabolic defect and changes in the values of LV ESV after 6 months the implantation of CRT device. Metabolic scintigraphy showed higher diagnostic efficacy in determination of indications for CRT compared with perfusion scintigraphy (AUC 0.722 and AUC 0.612, respectively). The best metabolic defect size threshold value of 7.35% predicted CRT efficacy with the sensitivity and specificity of 77.8% and 66.7%, respectively. We also mad an analytical review of methods for obtaining of radiopharmaceuticals that are based on 99mTc -labeled fatty acids and their use in cardiology. We make conclusion about efficiency of application and investigation of 99mTc fatty acids radiopharmaceuticals that contain chelate groups EDTA or DTPA. In this study, quantum-chemical modeling of one of such conjugate is conducted and its bioavailability is thus confirmed. Conclusions. The results of myocardial metabolic scintigraphy with 123I-BMIPP may be used as the secondary criteria for selection of patients for CRT and for prediction of the efficacy of this interventional treatment modality in patients with DCMP. This work was financially supported by Federal Target Program №14.604.21.0071(project unique identifier №RFMEFI60414X0071).

PW014

Association between radiation dosimetry of the heart and the myocardial fatty acid metabolic impairment due to chemoradiation-therapy : Prospective study using I-123 BMIPP SPECT/CT

K. Takanami[1], R. Umezawa[2], N. Kadoya[2], A. Arai[1], K. Jingu[2], K. Takase[1]; [1]Department of Diagnostic Radiology, Tohoku University Hospital, Sendai, JAPAN, [2]Department of Radiation Oncology, Tohoku University Hospital, Sendai, JAPAN.

Aim: The purpose of this study was to clarify the temporal change of the myocardial fatty acid metabolic impairment due to chemoradiation-therapy (CRT). Materials and methods: This study was approval by Institutional Review Board and the informed consent was obtained from all the patients. Twelve patients (3 females, mean age of 63.4 ± 7.1 years (53-79)) who underwent radical CRT for an early esophageal cancer. At pre-CRT, pre-boost irradiation during CRT, 3 months after CRT, and 1 year after CRT, I-123 BMIPP SPECT / CT was scanned. The myocardial BMIPP uptake in each of 17 segments of the left ventricle was visually scored from 0 (normal uptake) to 4 (no uptake) and semi-quantitatively assessed using “%uptake”, which is a segmental mean uptake relative to the maximal myocardial uptake. A correlation between radiation dosimetry of the heart and the change of myocardial BMIPP

uptake after CRT was assessed. P < 0.05 was considered as statistically significant. Results: One patient died of pneumonia during the course of observation, and 11 patients were followed for 1 year after the completion of CRT. The total dose to the primary tumor was 60-70 Gy. The average dose of the left ventricle was 15.7 ± 6.9 Gy, and mean V40 (a percentage of the left ventricle that had been irradiated 40 Gy or more) was 15.9 ± 15.0. Temporal decreases of the BMIPP uptake after CRT were observed. At pre-boost irradiation during CRT, 3 months and 1 y after CRT , the changes of total visual grade of the left ventricle were 1.1 ± 1.9, 2.7 ± 2.6, and 4.5 ± 4.1, respectively, and the changes of total %uptake of the left ventricle were -22.2 ± 50.4, -38.5 ± 54.3, and -81.1 ± 69.9, respectively. At 3 months after CRT, significant correlations were observed between V40 and both the total visual grade ($r = 0.63$, $p < 0.05$) and the total %uptake ($r = -0.74$, $p < 0.01$) , while, no significant correlation was observed 1 year after CRT. At pre-boost irradiation, a significant correlation was observed between V40 and only the total %uptake ($r = -0.64$, $p < 0.05$). Conclusion: Although a myocardial metabolic impairment after CRT is associated with radiation dosimetry of the heart in the short-term, other factors are likely to affect a myocardial metabolism in the long term.

PW015

The first clinical experience with combined PET-CT myocardium in patients with multivessel coronary disease.

I. Shurupova, I. Aslanidis, A. Chernova, V. Makarenko, V. Bereznitskiy, E. Derevyanko, I. . Ekaeva; Bakoulev Scientific Center for Cardiovascular Surgery, Moscow, Moscow, RUSSIAN FEDERATION.

The aim was the comparison the perfusion abnormalities and the severity of coronary atherosclerosis in patients with established coronary heart disease based on hybrid positron emission tomography with N13-ammonia (ammonium-PET) and multidetector computed tomography with noninvasive coronary angiography (MDCT-CA). Materials: 18 patients (44 to 80 years, 62,6 ± 9,8) underwent MDCT-CA, ammonium-PET stress - rest study on hybrid scanner Biograph-64 and invasive coronary angiography (Rg-CA), which was accepted as the "gold standard". A total of 42 coronary artery (CA) segments were taken for consideration. The hybrid imaging (MDCT-CA + ammonium-PET) and MDCT-CA allow results were compared with Rg-CA. Stenosis ≥75% was considered as significant lesion for invasive and non-invasive angiography. The result of the hybrid technology is considered true-positive if significant changes was detected by at least one of the non-invasive methods, negative if in the presence of intact arteries or stenosis <75% there is no the defect of perfusion (DP). Results. According to MDCT-CA stenosis in 14/19 arteries were properly verified revealed by Rg-CA. In the group of arteries with insignificant changes according to Rg-CA coincidence of the results indicated in 31/34 cases, one artery were excluded due to the artifacts. The sensitivity of MDCT-CA in identifying functionally significant stenosis was 73%, specificity - 91%, positive predictive value (PPV) - 82%, negative PV (NPV) - 86%. A sensitivity hybrid analysis amounted to 94%, specificity- 829%, PPV - 75%, NPV - 96%. Stenotic segments with the presence and absence of stress-induced DP were analyzed individually. According to PET DP were noted in 1/16 of the arteries with stenosis <50%, in the l 5/20 arteries in the group with stenosis 50-74%, in 11/17 arteries with stenosis ≥75%. In whole group (n=18) perceptions of the hemodynamic significance changes identified in the CA, based on invasive coronary angiography and on the basis of MSCT-AG + PET, coincided in 10 patients. The presence of significant stenoses was confirmed in 4 patients, absence hemodynamic significance was confirmed in 6. The initial view of the hemodynamic significance of a stenosis, compiled only on the basis of its size, have changed in 8/18 patients (44%). Conclusions. Hybrid studies allow to increase the sensitivity of diagnosis of significant stenosis. Lower specificity of hybrid researches is due to the lack of hemodynamic significance of some stenosis more than 75%. Generally hybrid researches allowed to change the perception of the stenosis hemodynamic relevance in 44% patients.

PW016

Assessment of Right Ventricular Myocardial Perfusion and Fatty Acid Metabolism Using Planar Imaging in Patients with Chronic Thromboembolic Pulmonary Hypertension

H. Miyauchi[1], T. Iimori[2], K. Sawada[2], Y. Kuwabara[1], S. Sakao[1], K. Tatsumi[1], Y. Kobayashi[1]; [1]Chiba University Graduate School of Medicine, Chiba, JAPAN, [2]Chiba University Hospital, Chiba, JAPAN.

[Background] In patients with chronic thromboembolic pulmonary hypertension (CTEPH), right ventricular (RV) overload may result in RV enlargement and hypertrophy, which consequently increases the RV myocardial perfusion. However, there is little information on the RV myocardial fatty acid metabolism in patients with CTEPH. [Aim] The aim of this study was to quantitatively evaluate the RV myocardial perfusion and fatty acid metabolism using 201Thallium (201Tl) and 123I-labelled 15-(p-iodophenyl)-3-R, S-methylpentadecanoic acid (123I-BMIPP) planar imaging in patients with CTEPH. [Materials and Methods] The study groups included 23 patients with CTEPH and 30 healthy controls. Mean pulmonary artery pressure (mPAP) by right heart catheterization was

obtained in all CTEPH patients. 201Tl and 123I-BMIPP planar and SPECT myocardial imaging were performed in all participants. Planar acquisition was performed by obtaining the angle that best separated the RV and the left ventricle (LV) on transverse imaging. In the planar image, we measured the total counts of 201Tl and 123I-BMIPP in both the RV and LV, and calculated their relative counts of the RV to LV (abbreviated as HR/HL(Tl) and HR/HL(BMIPP) , respectively) to determine the index of myocardial perfusion and fatty acid metabolism, respectively. [Results] HR/HL(Tl) was significantly elevated in the CTEPH patients compared with control (0.60 ± 0.14 vs. 0.36 ± 0.07, p <0.01). HR/HL(BMIPP) was also elevated in the CTEPH patients (0.55 ± 0.14 vs. 0.34 ± 0.06, p <0.01). In the CTEPH patients, average mPAP was 42.0 ± 9.52 mmHg, which was significantly correlated with HR/HL(Tl) (r=0.61, p<0.01) and HR/HL(BMIPP) (r=0.65, p<0.01). [Conclusions] In patients with CTEPH, RV myocardial perfusion was increased and RV myocardial fatty acid metabolism was upregulated with the elevation of mPAP. 201Tl and 123I-BMIPP planar imaging may be useful to quantify the severity of PH.

PW017

Diagnostic performance of attenuation corrected SPECT myocardial perfusion imaging for coronary artery disease: a systemic review and meta-analysis

J. Huang[1,2], M. Cheng[1], C. Lu[1,2], Y. Wu[1,3,4], R. Yen[1], K. Tzen[1], K. Chien[3,2]; [1]Department of Nuclear Medicine, National Taiwan University Hospital and National Taiwan University College of Medicine, Taipei, TAIWAN, [2]Institute of Epidemiology and Preventive Medicine, College of Public Health, National Taiwan University, Taipei, TAIWAN, [3]Division of Cardiology, Department of Internal Medicine, National Taiwan University Hospital and National Taiwan University College of Medicine, Taipei, TAIWAN, [4]Department of Nuclear Medicine and Cardiology Division of Cardiovascular Medical Center, Far Eastern Memorial Hospital, New Taipei, TAIWAN.

PURPOSE / INTRODUCTION: Coronary artery disease(CAD) is one of the major causes of mortality and morbidity throughout the world. Single photon emission computer tomography (SPECT) myocardial perfusion imaging (MPI) is a well established diagnostic tool for CAD. However, the full clinical potential of MPI has not been realized due to many factors of artifacts. Soft tissue attenuation is one of the most common artifacts. The aim of this study is to determine and compare the diagnostic performance of AC and non-AC SPECT MPI, using coronary angiography as the reference standard. SUBJECTS & METHODS: We search Medline and Embase for English-language literature published from the earliest available date till March 20, 2015 evaluating AC SPECT MPI for diagnosis of CAD. Extraction of information including author, journal, details of study design, patient characteristics, stressor used for MPI, radiotracer, CAD definition, numbers of true positive (TP),false positive (FP), true negative (TN) and false negative (FN) was performed. Assess methodological quality using the Quality assessment of Diagnostic Accuracy Studies (QUADAS) tool. All data from each eligible study were sorted out by Cochrane's Review Manger. For each study, the sensitivity, specificity, and the diagnostic odds ratio, along with the 95% confidence interval (CI), were calculated to express the diagnostic accuracy of AC and non-AC SPECT MPI. Because methodological heterogeneity between included studies was anticipated, a random-effects (DerSimonian and Laird) model was used for pooling the data. Statistical analysis was performed using STATA and Meta-DiSc. RESULTS: Original search yielded 201 articles. On the basis of title and abstract, we exclude 158 articles. One the basis of full text, we exclude 26 articles for various reasons, such as study for rick stratification, reference standard other than coronary, etc. Seventeen studies were identified, with a total of 1763 patients; 5 studies with 582 patients used computed tomography AC (CTAC); 12 studies with 1181 patients used radionuclide source AC; 12 studies with 1605 patients reported non-AC results. Meta-analysis yielded pooled sensitivities of 0.748 [95%CI, 0.698-0.794], 0.810 [95% CI, 0.0.784-0.834] and 0.786 [95% CI, 0.757-0.812] for CTAC, all AC and non-AC, respectively, and pooled specificities of 0.82 [95% CI, 0.768-0.867], 0.817 [95% CI, 0.786-0.844] and 0.705 [95% CI, 0.668-0.739], respectively. DISCUSSION / CONCLUSION: Attenuation correction SPECT MPI with either CTAC or radionuclide source AC showed improvement in both sensitivity and specificity. Our results suggested that AC should be applied in SPECT MPI for better diagnosis of CAD.

PW018

Systematic Underestimation of High Values of Coronary Flow Reserve Provided with Multi-Detector Computed Tomography: a Comparison with SPECT Technology.

M. Bauckneht[1], G. Ferrarazzo[1], F. Fiz[1], S. Seitun[2], C. Zawaideh[3], F. Ticconi[1], I. Calamia[1], S. Morbelli[1], C. Brunelli[3], C. Ferro[2], G. Bezante[3], G. Sambuceti[1], C. Marini[4]; [1]Nuclear Medicine, IRCCS AUO San Martino IST, Genova, ITALY, [2]Department of Radiology and Interventional Radiology, IRCCS-University Hospital San Martino-IST, Genova, ITALY, Genova, ITALY, [3]Department of Internal Medicine, Chair

of Cardiology, University of Genoa, Genova, ITALY, Genova, ITALY, [4]Institute of Bioimaging and Molecular Physiology, CNR, Milan, Genoa Section, Genova, ITALY, Genova, ITALY.

Aim. Diagnostic information provided by multi-detector computed tomography (MDCT) has been recently enriched with myocardial perfusion imaging (MPI) and the possibility to assess coronary flow reserve (CFR). However, the accuracy of this method has so far poorly evaluated and reported normalcy values are markedly lower with respect to corresponding measurements with gold standard techniques. The present study was planned to compare performance of MDCT and SPECT in CFR quantification since this numeric descriptor of coronary physiology represents the theoretical basis of MPI diagnostic accuracy. Materials and Methods. Thirty-five patients (29 males, mean age 69 years) referred for chest pain and/or dyspnea to our Institute underwent dipyridamole stress/rest MPI with MDCT and SPECT. MDCT approach implied the use of a commercially available software able to diplay parametric maps of myocardial blood flow using a two-compartment model in LV myocardial tissue. SPECT measurements were instead performed, according to the validate method that implies the normalization of myocardial tracer uptake for the corresponding input function. For both approaches CFR values were compared with the anatomy of related coronary branch as depicted by CT coronary angiography. Results. Overall, CFR values at SPECT and MDCT imaging were similar (1.51±0.46 vs 1.50±0.37, respectively, p=ns) and showed a fair segment-by-segment correlation (r=0.63, p<0.001). At SPECT analysis, CFR was 1.64±0.31 in the 164 segments supplied by normal arteries (control regions), while it significantly decreased in the 114 areas supplied by vessels with intermediate stenosis (≤50%) (intermediate: 1.50±0.32, p50%) (critical: 1.33±0.22, p<0.01 vs control regions). MDCT-CFR was 1.65±0.32 in control regions and significantly decreased to similar values in intermediate (1.40±0.33 p<0.01 vs control regions) and in critical ones (1.36±0.26, p<0.01 vs control regions). At Bland-Altman analysis, a proportional bias was identified by the regression between delta (SPECT CFR - MDCT CFR) and mean CFR value that was significant (p<0.01) and displayed a positive slope of 0.288 with 95% confidence limits ranging from +0.21 to +0.31. Conclusions. MDCT-MPI and SPECT provide similar values of regional CFR in a population with suspected CAD. However, MDCT displays a limited accuracy in measuring high maximal MBF and CFR values. This limitation can be recognized even by the comparison with SPECT technology, which is known to markedly underestimate high MBF and CFR values. An accurate validation of MDCT diagnostic performance should be completed encompassing a normalcy database to optimize its diagnostic use.

PW019

Cardiac Sympathetic Innervation Assessed with 123I-MIBG Retains Prognostic Utility in Diabetic Patients with Severe Left Ventricular Dysfunction Evaluated for Primary Prevention Implantable Cardioverter-Defibrillator

M. COZAR SANTIAGO[1], P. GARCIA GONZALEZ[2], R. SANCHEZ JURADO[1], R. SANZ LLORENS[1], J. AGUILAR BARRIOS[1], F. RIDOCCI SORIANO[2], J. FERRER REBOLLEDA[1]; [1]ERESA-NUCLEAR MEDICINE DEPARTMENT. GENERAL UNIVERSITARY HOSPITAL, VALENCIA, SPAIN, [2]ERESA-CARDIOLOGY DEPARTMENT. GENERAL UNIVERSITARY HOSPITAL, VALENCIA, SPAIN.

OBJECTIVES: We analyze if the evaluation of cardiac sympathetic innervation (CSI) with iodine-123-metaiodobenzylguanidine (123I-MIBG) retains prognostic utility in diabetic patients with heart failure (HF) evaluated for primary prevention implantable cardioverter-defibrillator (ICD).BACKGROUND: Scintigraphy with 123I-MIBG is a noninvasive tool for the assessment of CSI that has proven to be an independent predictor of survival. In addition, recent studies have shown that diabetic patients with HF have a higher deterioration in CSI. It is unknown if 123I-MIBG has the same predictive value for diabetic and nondiabetic patients.METHODS: Seventy-eight consecutive HF patients (48 diabetic and 30 nondiabetic) evaluated for primary prevention ICD implantation were prospectively enrolled and underwent 123I-MIBG to assess CSI (Heart-to-mediatinum ratio (HMR), cardiac wahout rate). A Cox proportional hazards multivariate analysis was used to analyze the influence of 123I-MIBG images for prediction of cardiac events in both diabetic and non-diabetic patients. The primary end-point was a composite of arrhythmic event, cardiac death or HF hospitalization.RESULTS: During a mean follow-up of 19.5 [9.3-29.3] months, the primary end-point occurred in 24 (31%) patients. Late HMR was significantly lower in diabetic patients (1.30 vs 1.41, p=0.014). Late HMR ≤1.30 was an independent predictor of cardiac events in diabetic (hazard ratio 4.53; p = 0.012) and non-diabetic (hazard ratio 12.31; p = 0.023) patients.CONCLUSIONS: Diabetic patients with HF evaluated for primary prevention ICD show a higher deterioration in CSI than non-diabetics; nevertheless 123I-MIBG imaging retained prognostic utility for both diabetic and non-diabetic patients

PW020
18F-FDG PET-CT in the Diagnosis of Infective Endocarditis over Native and Prosthetic Valves

A. Jiménez-Ballvé[1], M. J. Pérez-Castejón[1], M. Matínez de Bourio[1], C. Sánchez-Enrique[2], I. Vilacosta[2], C. Riola Parada[1], A. Ortega Candil[1], C. Olmos[2], J. L. Carreras-Delgado[1,3]; [1]Nuclear Medicine Department, Hospital Clinico San Carlos, Madrid, SPAIN, [2]Cardiology Department, Hospital Clinico San Carlos, Madrid, SPAIN, [3]Universidad Complutense, Madrid, SPAIN.

Aim: The aim of this study was to assess the usefulness of PET-CT with 18F-FDG in the diagnosis of infective endocarditis (IE) looking for differences among native and prosthetic valves. Materials and methods: In this prospective study we included 52 patients with initial suspicion of definitive or possible IE according to Dukes criteria, from November 2012 to April 2015. PET-CT was considered positive when presented 18F-FDG uptake in the region of interest (ROI) greater than the background and persisted in the non-corrected images. On the other side, it was considered negative if there was no uptake difference between the ROI and the background or did not persist in the non-corrected images. Anatomy was the gold standard in patients who underwent cardiac surgery. In those cases without surgery, final diagnosis was done by clinical consensus of the endocarditis team (independently from the PET-CT results). Results: In the 52 PET-CT studies, we analyzed 69 foci as regions of interest, 42 prosthesis valves and 27 native valves. The suspicion of IE was 38 definitive and 31 possible. PET-CT was positive in 39 cases (57%) and negative in the other 30 (43%). 21 valve replacements were performed: 19 definitive IE (11 on prosthesis and 8 on native valves, with a PET-CT success rate of 100% and 38%, respectively) and 2 rejected IE (fibroelastoma and marantic IE, both on native valve with a PET-CT success rate of 100%). sensibility, specifity, positive predictive value (PPV), negative predictive value (NPV) and accuracy of PET-CT in global IE (prosthesic+natives) were 79%, 73%, 79%, 73% and 77%, respectively. When we just analyzed prosthesis, we achieved a very high sensibility and NPV (100%), with a specifity of 70%, PPV of 79% and an accuracy of 86%. By contrast, when we analyzed independently native valves, we obtained a sensibility of 52%, specifity of 80%, PPV of 81%, NPV of 50% and an accuracy of 63%. Conclusion: 18F-FDG PET-CT seems to be useful in the diagnosis of infective endocarditis, especially in patients with prosthesis valves, having better accuracy than in native valves.

[18F]DPA-714: peripheral metabolism in healthy volunteers and patients.

M. Peyronneau[1], C. Letaillandier[1], S. Lavisse[2], B. Kuhnast[1], C. Baron[1], B. Jego[1], P. Gervais[1], F. Dollé[1], B. Bodini[3], B. Stankoff[3], M. Sarazin[3], P. Rémy[2], M. Bottlaender[4]; [1]CEA-DSV-I2BM-SHFJ-IMIV, Orsay, FRANCE, [2]CEA-DSV-I2BM-Mircen, Orsay, FRANCE, [3]APHP, Paris, FRANCE, [4]CEA-DSV-I2BM-Neurospin-IMIV, Orsay, FRANCE.

Objectives: The translocator protein (TSPO) is weakly expressed in the healthy human brain and overexpressed in several neurodegenerative pathologies. [18F]DPA-714 is currently under clinical investigation in Alzheimer, Parkinson and Multiple Sclerosis diseases by PET. We have previously reported species differences in the metabolism of [18F]DPA-714 in rats and non-human primates and the involvement of human CYP3A4 in its biotransformation (Peyronneau et al., Drug Metab Dispos, 2013). In this study, we aimed to investigate the peripheral metabolism of [18F]DPA-714 in healthy volunteers (HV) and patients (P) and evaluate the influence of age, gender, diseases, concomitant medication and binder affinity for TSPO.Methods: Venous blood samples were collected from 145 subjects (54 HV-91 P) during PET and arterial samples in 20 HV. [18F]DPA-714 and metabolites fractions were determined by a developed solid phase extraction method and used for the correction of individual input functions. Results: As expected, [18F]DPA-714 peripheral metabolism was similar in arterial and venous plasma samples (54.8±9.7% vs 54.5±9.6% of [18F]DPA-714 at 90 min). No gender differences were observed but [18F]DPA-714 metabolism decreased with age (45±10% to 35±10% of radiometabolites; 20-90 years, $p<0.05$). No significant differences were detected between healthy volunteers and patients, except for those co-medicated with known CYP3A4 inducers/inhibitors, for whom an increase (up to 66%) or a decrease (down to 12%) of radiometabolites were observed. Finally, while no major difference in the metabolism was found whatever the TSPO affinity genetic status, the parent plasma concentration (input function) displayed a 4-fold and 1.3-fold increase in low and mixed compared to high binders.Conclusions: [18F]DPA-714 metabolism may contribute to interindividual variations of the input function used for the quantification of the tracer brain uptake.

A Novel SPECT-based Approach Reveals Early Effects of Systemic Inflammation on Brain Injury and Peripheral Organs After Cerebral Ischemia

D. Mathe[1], K. Szigeti[2], D. Veres[2], B. Martinecz[3], N. Lenart[3], N. Kovacs[1], A. Marta[2], M. Semjeni[1], A. Denes[3,4]; [1]CROmed Ltd, Budapest, HUNGARY, [2]Dept. Biophysics and Radiation Biology Semmelweis University, Budapest, HUNGARY, [3]Laboratory of Molecular Neuroendocrinology, Institute of Experimental Medicine, Budapest, HUNGARY, [4]Faculty of Life Sciences, University of Manchester, Manchester, UNITED KINGDOM.

Introduction. Inflammation that develops in the brain and peripheral organs after stroke contributes profoundly to the outcome of patients. Clinical decision making would highly benefit from rapid assessment of central and peripheral inflammatory changes after acute brain injury, but appropriate medical imaging tools are not available yet. Here we show that single-photon emission computed tomography combined with MRI (NanoSPECT/CT Plus, nanoScan MRI/SPECT) allows early visualization of blood brain barrier injury and inflammation in the brain after experimental stroke, well before signs of brain injury can be detected with magnetic resonance imaging (MRI).Materials and Methods. Whole-body 99mTc-DTPA SPECT/CT; 99mTc-HMPAO SPECT and MRI imaging was performed in groups of 5 mice with middle cerebral artery occlusion (MCAO) for 30 or 60 minutes. In one group LPS-induced systemic inflammation was present before the MCAO to model pre-existing inflammatory diseases. Imaging was done 1, 3, 6 and 24, 72 hours post MCAO and was validated by IgG, CD45 and Iba1 immunofluorescent microscopy and H&E staining in respective brains and peripheral organs.Results. Penetration of 99mTc-DTPA into the brain parenchyma overlaps with areas of brain injury and perfusion deficits after cerebral ischemia. Systemic inflammation preceding experimental stroke leads to very early perfusion deficits and increased blood brain barrier injury (within 2 h) after the onset of ischemia. Acute brain injury also leads to infectious complications in peripheral organs such as the lung. We detected that SPECT imaging reveals early (within 1-3 h) changes in perfusion, barrier function and inflammation in the lungs and the gut of all mice after experimental stroke, with good predictive value for outcome. Discussion. Our results suggest that early inflammatory changes as detected by SPECT/MRI, SPECT/CT whole-body imaging precede injury in the brain and peripheral organs. Thus these hybrid nuclear medicine imaging methods are proposed to support decision making in the clinic.

PW023

Effect of Normobaric Hyperoxia (NBO) on Hypoxic Volume and Infarct Volume Following Middle Cerebral Artery Occlusion (MCAo): An 18F-Fluoromisonidazole (FMISO) PET, MR and TTC Study

T. D. Fryer, S. Ejaz, D. J. Williamson, U. Jensen-Kondering, S. J. Sawiak, F. I. Aigbirhio, Y. T. Hong, J. Baron; University of Cambridge, Cambridge, UNITED KINGDOM.

Aim: Whether NBO is effective in reducing infarct volume in ischemic stroke remains inconclusive. NBO modestly increases arterial oxygen content, which in turn may not significantly alleviate tissue hypoxia. We determined the impact of NBO in two rat strains with different leptomeningeal collaterals. Materials and Methods: 6 Wistars and 7 SHRs underwent distal permanent MCAo (pMCAo) under either normoxic or hyperoxic conditions. Dynamic FMISO PET data were acquired for 3hrs ~5min after occlusion. Hypoxic volumes were defined on SUV2-3hrs maps. Kinetic modeling was applied to the hypoxic volume signal. Lesion volume was defined immediately after PET by T2w-MR and TTC. Additional rats were used to measure arterial PO2 (PaO2) and MCA cortex PO2 (PtO2) using an O2 probe during cycles of normoxia/NBO. Results: In SHRs, NBO increased PaO2 ~4-fold from normoxia; non-ischemic cortex PtO2 rose from mean 24 to 50mmHg in SHRs (n=5; p=0.04), and from 46 to 78mmHg in Wistars (n=4; p=0.001). During MCAo, in SHRs compared to Wistars PtO2 was lower in normoxia (2.5 vs 15mmHg) and increased less with NBO: 6mmHg (p=0.08) vs 26mmHg (p=0.09), respectively. FMISO hypoxic volume was much larger in SHRs than Wistars, but was not significantly different between normoxia and NBO in either strain (mean 207 vs 349mm3 in SHRs, and 11 vs 9mm3 in Wistars). FMISO influx rate (Ki) was significantly increased ($p<0.03$) in the hypoxic volume compared to a mirror ROI for both rat strains under both conditions, with trapping rate (k3) also increased in SHRs ($p<0.05$) with a similar trend in Wistars ($p<0.09$). However, mean SUV, Ki and k3 in the hypoxic volume were not significantly different between normoxia and NBO in either strain. A similar pattern was found for TTC (mean 136 vs 179mm3, and 18 vs 11mm3, respectively) and MR (mean 91 vs 103mm3, and 7 vs 3mm3, respectively) lesion volumes. There were strong ($p<0.001$) correlations among lesion volumes from TTC, MR and FMISO. Conclusion: Regardless of strain, there was no protective effect of NBO against tissue hypoxia and infarction. The latter is consistent with previous pMCAo studies, all in Sprague-Dawleys. However, here we directly show no effect on FMISO lesion volume and only mild effects on tissue PtO2. Early reperfusion is probably necessary for NBO to show benefit, even with good collaterals. The worse tissue hypoxia during

MCAo in SHRs is consistent with their intrinsically poorer vascular architecture, apparent from their lower non-ischemic hemisphere PtO2 under normoxia.

PW024

Regional cerebral blood flow changes after accelerated repetitive transcranial magnetic stimulation of the canine frontal cortex.

R. Dockx[1], C. Baeken[2], R. Duprat[2], F. De Vos[3], B. De Spiegeleer[3], A. Dobbeleir[1], J. H. Saunders[1], I. Polis[1], K. Audenaert[2], K. Peremans[1]; [1]Faculty of Veterinary Medicine, University Ghent, MERELBEKE, BELGIUM, [2]Faculty of Medicine, University Ghent, Ghent, BELGIUM, [3]Faculty of Pharmaceutical Sciences, University Ghent, Ghent, BELGIUM.

Repetitive transcranial magnetic stimulation (rTMS) is a non-invasive, FDA approved treatment for depression. Nevertheless, this treatment's neurobiological mechanisms remain unclear. Aim: To compare the regional cerebral bloodflow prior and after High Frequency accelerated Repetitive Transcranial Magnetic Stimulation (HF-arTMS) of the normal canine left frontal cortex. Material and Methods: Eight dogs underwent a 3 Tesla MRI scan at the Ghent University Hospital. This scan was the basis for pointer-based neuronavigation (Brainsight 2, Rogue Resolutions, LTD), a technique used to externally locate the stimulation site. Each dog's left frontal cortex was subjected to 5 consecutive stimulation sessions a day with a figure 8 coil (Magstim Company Limited, Wales, UK) at 20 Hz. The sessions consisted of 40 trains of 1.9 seconds duration, separated by a 12 second intertrain interval (1560 pulses per session). The stimulation intensity was set at 110% of the motor threshold. One day prior and after the last stimulation session, a 99mTc-HMPAO SPECT scan was acquired under general anaesthesia. SPECT data were acquired with a triple head gamma camera (Trionix, Triad) 30 minutes after tracer injection (step and shoot, 120 steps of 3 deg, 10" per step). The data were reconstructed with OSEM reconstruction and application of resolution recovery algorithms (Hybrid, Hermes, NUD, Sweden). A BW filter was applied (cut-off 1.6 cycles/cm, order 5). The perfusion indices (PI) in the frontal, parietal, temporal, rostral cingulate and caudal cingulate cortex as well as subcortical regions (thalamus, striatum) were obtained by semi quantification (normalization to total brain counts). A Wilcoxon signed rank test was used to analyze the perfusion indices. Significance level was set at $p \leq 0.05$. Results: The stimulation sessions caused a significantly increased PI in the left frontal cortex ($p = 0.01$) and a decrease in the right parietal cortex ($p = 0.03$). No significant differences were noted for the other regions compared to baseline. Conclusions: Accelerated HF-rTMS of the frontal cortex in dogs provokes an increase in rCBF at the stimulation site. This finding is line with its effects in humans and implies that rTMS may be used as a treatment for canine behavioral disorders. Further investigation is needed to evaluate the stimulation parameters and long-term effects of such stimulation.

PW025

Metabolism of the Spinal Cord in Patients With Amyotrophic Lateral Sclerosis: A FDG-PET/CT Study.

E. Pomposelli[1], G. Sambuceti[1], M. Piana[2], C. Campi[2], M. Pennone[1], A. Buschiazzo[1], A. Cistaro[3], F. Bongioanni[1], A. Chiò[4], F. Nobili[5], C. Caponnetto[6], C. Marini[7]; [1]Nuclear Medicine Unit, Department of Health Sciences, University of Genoa and IRCCS AOU San Martino-IST, Genoa, ITALY, [2]Department of Mathematics, University of Genoa, Genoa, ITALY, [3]Positron Emission Tomography Centre IRMET S.p.A., Euromedic inc, Turin, ITALY, [4]Department of Neuroscience "Rita Levi Montalcini", University of Turin, Turin, ITALY, [5]Clinical Neurology, IRCCS AOU San Martino-IST, Genoa, ITALY, [6]Department of Neuroscience, IRCCS AOU San Martino-IST, Genoa, ITALY, [7]CNR Institute of Bioimages and Molecular Physiology, Section of Genoa, Genoa, ITALY.

Aim. Amyotrophic lateral sclerosis (ALS) is a fatal late-onset neurodegenerative disorder of adult life, characterized by a progressive impairment of motor function. Its pathological feature is characterized by selective cell loss in the anterior horns of the spinal cord (SC) and in the lower motor cranial nerve nuclei as well as by cortico-spinal tract degeneration. We recently developed new software able to identify compact bone profile in PET/CT images and thus able to recognize the spinal canal and SC tracer uptake. The aim of our study was to investigate whether this method permits to identify abnormalities in SC metabolism in ALS patients. Materials and Methods. We studied 41 ASL patients at different clinical stage, submitted to FDG-PET/CT imaging. Patient population was compared with matched healthy controls, randomly selected from a published normalcy database. Image analysis was performed according to a previously validated method. The algorithm first identified the skeleton on the whole body CT images by assuming that compact bone was the structure with the highest X-ray attenuation coefficient in the human body. Once identified the skeletal border, all vertebrae were extracted from the image data set. The spinal canal was automatically identified as the non-osseous space within the spine volume. The output of the software was therefore the extraction and the 3D-representation of spinal canal volume that served as a mask to recognize SC using a segmentation algorithm based on Hough transformation. Thereafter, mean standardize uptake value (SUV) of cervical and dorsal SC, normalized to the liver, was evaluated in comparison with normal subjects. Cervical and dorsal SUV-mean normalized was considered in ASL patient both

untreated and treated with riluzole. Results. Mean SC SUV was significantly higher in ALS patients than controls in cervical (0.97±0.39 vs 0.85±0.20, p<0.05) and dorsal (0.71±0.21 vs 0.67±0.15, p<0.05) SC segments. This increase was virtually abolished in the 21 patients submitted to riluzole respect to untreated patients in both cervical (0.85±0.25 vs 1.11±0.46, p<0.05) and dorsal (0.65±0.14 vs 0.77±0.25, p<0.05) segments. By contrast no differences were found in SC volume between patients and controls or treated and untreated patients. Conclusion. This new computational FDG-PET/CT analysis provided evidence of relative increase metabolism in SC of ALS patients with respect to controls. Moreover, riluzole therapy seems to reduce SC FDG uptake. This method could improve our understanding of SC response to ALS and the effect of new possible therapeutic approaches.

PW026

Imaging of Brain TSPO Expression in a Mouse Model of Amyotrophic Lateral Sclerosis with [18F]DPA-714 and Micro-PET/CT.

S. Gargiulo[1,2], S. Anzillotti[3], A. Coda[1], M. Gramanzini[1,2], A. Greco[4,2], M. Panico[1], F. Dollé[5], G. Pignataro[6], M. Quarantelli[1], L. Annunziato[6,3], A. Brunetti[4,2], M. Salvatore[3], S. Pappatà[1]; [1]Institute of Biostructure and Bioimaging, CNR, Naples, ITALY, [2]Ceinge, Biotecnologie Avanzate s.c.a r. l., Naples, ITALY, [3]SDN IRCCS, Naples, ITALY, [4]Department of Advanced Biomedical Sciences, University Federico II, Naples, ITALY, [5]CEA, Institute for Biomedical Imaging, Orsay, FRANCE, [6]Department of Neuroscience, Reproductive and Dentistry Sciences, Naples, ITALY.

Aim: Amyotrophic lateral sclerosis (ALS) is a progressive neurodegenerative disease affecting the motor system. Transgenic SOD1G93A mice, carrying an ALS-linked mutant human superoxide dismutase gene, provide a relevant tool to investigate in vivo neuroinflammation with translocator protein (TSPO, 18 kDa) radioligands. We evaluated the feasibility of imaging microglial activation in SOD1G93A mice using [18F]DPA-714. Material and Methods: 5 non-carrier and 9 hemizygous SOD1G93A mice (aged 71-137 days) were evaluated at different symptomatic clinical stages (CS, score range: 0.5-4). High-resolution PET/CT (GE Healthcare eXplore Vista, resolution: 1.8 mm FWHM/200 μm) were performed under inhalant anesthesia (isoflurane 2%, oxygen 2 L/min). Images were acquired in dynamic mode over 30 minutes starting 20 minutes after tail vein injection of 5.55-7.00 MBq of [18F]DPA-714 (SRA: 200-800 GBq/μmol), and were processed using a 2D-OSEM iterative algorithm including random, scatter, dead time, and decay correction. Counting rates were converted to Standardized Uptake Values (SUV=Tissue activity (MBq/cc)/[Injected dose (MBq)/body weight (g)]). ROIs were defined based on PET/CT fusion images on the cerebellum, brainstem, cervical spinal cord and frontal cortex using OsiriX software. Cerebellar, brainstem and cervical spinal cord SUV were normalized to those of the frontal cortex. Statistical analysis was performed using Mann-Whitney test and Pearson's correlation. Immunostaining and confocal immunofluorescence were performed on brain and spinal cord sections using rabbit anti-TSPO and mouse anti-Iba1 antibodies. Results: In the SOD1G93A symptomatic mice the region/frontal cortex ratio was significantly increased (p=0.012) in the brainstem (2.340 ±0.784) compared to non-carriers (1.576±0.287). There was no significant correlation between [18F]DPA-714 brainstem/frontal cortex ratio and clinical scores. Preliminary results of immunofluorescence studies showed increased TSPO expression in the spinal cord, in the facial nucleus and in the nucleus ambiguus of symptomatic SOD1G93A mice that colocalizes with increased Iba1 staining. Conclusions: The preliminary results suggest that increased [18F]DPA-714 uptake can be measured with high resolution PET/CT in a mouse model of ALS in the brainstem, a region known to be the site of degeneration and increased microglial activation. Immunostaining results showed that TSPO expression is increased in brainstem nuclei and suggest that increased microglial activation might be the cellular counterpart of in vivo increased [18F]DPA-714 uptake. Acknowledgement: The research leading to these results has received funding from the European Union's Seventh Framework Programme (FP7/2007-2013) under grant agreement n° HEALTH-F2-2011-278850 (INMiND).

PW027

Positive correlation between neuromelanin accumulation in the substantia nigra and striatal dopaminergic innervation in patients with Parkinson's disease

G. Marotta[1], I. U. Isaias[2], A. Costa[1], P. Trujillo[1], P. Summers[1], G. Pezzoli[3], R. Benti[1]; [1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, ITALY, [2]Department of Neurology, University Hospital, Wurzburg, GERMANY, [3]Parkinson Institute, Istituti Clinici di Perfezionamento, Milano, ITALY.

Objectives: Parkinson's disease (PD) is a progressive neurodegenerative disorder in which the major pathologic substrate is a loss of dopaminergic neurons form the substantia nigra (SN). Our main objective was to determine in PD patients the correspondence between SN changes, evident in neuromelanin (NM)- and iron-sensitive MRI images, and dopaminergic striatal

innervation loss. Methods: The study involved 18 subjects with PD (13 males; median age: 64 years, range: 46-77 years) and a control group of 18 neurologically intact adults (HC; 11 males; median age: 58 years, range: 47-77 years). All subjects were examined at 3T MRI by means of NM-sensitive and T2*-weighted multi-echo gradient echo sequences. Using NM-MRI, we measured the volume of the SN (Volsn) and the mean contrast-to-noise-ratio (CNRsn) between SN and a background region. The susceptibility (χ) and R2* of the SN were calculated from multi-echo T2* images. Striatal dopaminergic innervation was measured as density of dopamine reuptake transporters (DAT) by means of FP-CIT SPECT, on the basis of VOIs defined by means of the Basal Ganglia Matching Tool. Results: When compared to a pre-existing group of HC, all PD patients had significantly reduced striatal DAT binding values in both putamen (PT) and caudate nucleus (CN). The reduction was greater on the side contralateral to the most affected hemibody. PD patients showed a reduced Volsn and CNRsn and both positively correlated with the corresponding striatal DAT density. R2* and χ values of SN did not differ between PD and HC. The best predictor of DAT reduction was Volsn ($p<0.001$, Press value=9.33). With reference to our HC cohort, the probability of having PD was 100% when Volsn-contra<0.35 cm3 and 32% if Volsn-contra≥0.35 cm3. Conclusions : NM-MRI is a means of quantifying SN pathology in PD patients that closely correlates with dopaminergic striatal innervation loss. It may serve as an imaging marker of PD, in particular regarding SN neuron loss, although further longitudinal multi-imaging studies, possibly involving subjects at risk of PD, are required.

PW028

Quantification of Amyloid-β Deposition Using ^{18}F-FC119S PET in Human Brains: A Phase 0-1 Study.

B. Byun[1], B. Kim[1], I. Lim[1], C. Choi[1], S. Park[2], J. Ha[2], K. Lee[3], K. Kim[3], S. Lim[1]; [1]Department of Nuclear Medicine, Korea Cancer Center Hospital, Korea Institute of Radiological and Medical Sciences, Seoul, KOREA, REPUBLIC OF, [2]Department of Neurology, Korea Cancer Center Hospital, Korea Institute of Radiological and Medical Sciences, Seoul, KOREA, REPUBLIC OF, [3]Molecular Imaging Research Center, Korea Institute of Radiological and Medical Sciences, Seoul, KOREA, REPUBLIC OF.

Aim: ^{11}C-PIB has been developed and used to measure amyloid-β deposit in the brain, which can be applied for early diagnosis and evaluation of progression of Alzheimer's disease (AD). However, several ^{18}F-labeled radiotracers with a longer half-life were introduced in clinical practice with different characteristics. The aim of the present phase 0/1 study was to obtain information about dosimetry, toxicity, pharmacokinetics, optimal dose, and optimal scan time of ^{18}F-FC119S, a new amyloid-β radiotracer.Materials and methods: Eleven control subjects (mean age = 23.0 y) and 8 clinically-diagnosed AD patients (mean age = 70.6 y) were enrolled (M: F = 9: 10). In phase 0 study, we acquired a 120 min dynamic brain PET image (3 control subjects and 3 AD patients) or 5 times of whole-body PET images during 4 hr (for dosimetry evaluation in 3 control subjects) after injection of 185 MBq of ^{18}F-FC119S. In phase 1 study, we acquired a 60 min dynamic brain PET image in 5 control subjects and 5 AD patients after injection of 370 MBq of ^{18}F-FC119S. The ratios of cerebral gray matter uptake to cerebellar uptake of ^{18}F-FC119S (C/Cbr) were automatically calculated on each PET dataset. Then, PET data acquired for 10 min, 20 min, and 30 min after the plateau of C/Cbr were respectively reconstructed. Quality of these reconstructed images was visually assessed (good/acceptable/poor) and a case with higher or equivocal gray matter uptake compared to the white matter uptake on visual analysis was considered as a PET+.Results: The estimated whole-body radiation dose was 14.7 μSv/MBq and the highest uptake was observed in the liver or gallbladder. No adverse event was observed. C/Cbr continuously increased during the first 30 min after injection of ^{18}F-119S then did not change over 120 min. The mean C/Cbr of AD patients and control subjects at plateau phase was 1.57 and 1.11, respectively. All the PET images acquired during 30-60 min irrespective of injected dose and all the PET images acquired during 30-50 min after injection of 370 MBq of ^{18}F-FC119S showed good image quality, while others showed poor or acceptable image quality. On visual analysis, 6 of 8 AD patients (75%) and 0 of 8 control subjects (0%) showed PET+.Conclusion: ^{18}F-FC119S is safe and its kinetic behavior is suitable for measuring amyloid-β in the brain. PET images acquired during 30-50 min after injection of 370 MBq of ^{18}F-119S showed good image quality.

PW029

Comparison of Visual and Quantitative 18F-Florbetaben PET Scan Assessment

J. Seibyl[1], S. Bullich[2], D. Jennings[1], M. Sabbagh[3], A. Stephens[2], H. Barthel[4], O. Sabri[4], A. Catafau[2]; [1]Molecular Neuroimaging, New Haven, CT, UNITED STATES, [2]Piramal Imaging, Berlin, GERMANY, [3]Univ of Arizona, Phoenix, AZ, UNITED STATES, [4]Univ Leipzig, Leipzig, GERMANY.

Background: Visual interrogation of 18F-Florbetaben (FBB) PET scans is currently recommended for clinical practice,

while quantification using SUVRs is a research tool which has been considered a potentially important adjunct to aid overall scan assessment. However, the added value of quantification for the clinical scan report is unknown. This study aims to compare both assessment methods for FBB PET scans to determine whether analysis of concordance/discordance between the assessments offers insight into how a visual-quantitative assessment algorithm might perform. Methods: A total of 190 FBB scans were evaluated. 109 scans were from n=70 young (27.7 ± 5.1 yrs) cognitively normal subjects (HVs) assumed to be devoid of brain beta-amyloid and n=39 subjects with Down syndrome (DS) > 40 yrs old (46.3 ± 4.7 yrs), and an additional 81 subjects scans were from a Phase 3 histopathology confirmation study. All scans were visually assessed by 3 readers using the brain amyloid plaque load (BAPL) scoring system, where negative scan=BAPL 1, and positive scan is either BAPL 2=moderate or BAPL 3= pronounced tracer uptake. Positive or negative scan agreement in ≥2 readers was considered as the result. A composite SUVR using cerebellar cortex as reference was obtained from the average SUVR in 6 cortical regions, using an automated grey/white matter MRI segmentation and PET-MRI co-registration. Composite SUVR ≥1.45 were considered positive. Results: All scans from HVs were visually assessed as negative. 91.1% of the scans were equally classified as positive or negative by both visual and quantitative approaches. Both methods were significantly and strongly related (X2 = 125, p < 0.0001; Cohen's Kappa = 0.81). In the 17 scans showing discrepancy, SUVRs range from 1.01-1.67, and readers gave divergent BAPL scores in half these cases. These challenging scans exhibited different features: poor technical quality, motion, and atrophy. In the histopathology cohort, for 6 cases with severe cortical atrophy the visual reads were more concordant with histopathology than quantitation. Conclusions: These findings support the use of either visual or quantitative assessment of FBB scans. Further investigation is required to determine the clinical utility of SUVR quantification in challenging scans.

PW030

Striatal dopamine transporter modulation after rotigotine: results from a pilot SPECT study in a group of early Parkinson's disease patients.

E. Filidei[1], C. Rossi[2], D. Genovesi[1], P. Marzullo[1], A. Giorgetti[1], G. U. Corsini[2], U. Bonuccelli[2], R. Ceravolo[2]; [1]Fondazione Toscana G. Monasterio, Pisa, ITALY, [2]Azienda Ospedaliero-Universitaria Pisana, Pisa, ITALY.

Introduction. Several in vitro data reported negative interference by dopamine-agonists on the expression of dopamine transporter (DAT) whereas from the most imaging studies nor L-dopa or dopamine-agonist resulted to interfere with DAT availability. The investigation on DAT expression by rotigotine in vivo has been not investigated yet. Methods. We evaluated presynaptic nigrostriatal function in 8 de novo Parkinson's disease (PD) patients (age 59±6.2 years; M/F 5/3) using FP-CIT SPECT before and after 3 months of treatment with rotigotine (mean dose 7.75±1.98 mg). For data analysis, specific (left and right caudate, left and right putamen) to non-specific (occipital cortex) binding ratios, putamen to caudate ratios and asymmetry indexes were calculated. Results. After rotigotine all patients improved motor symptoms (UPDRS III mean score 11.88±2.59 vs 7.63 ±1.92 on therapy, p=0.0022). Striatal FP-CIT levels showed a significant improvement in each patient at the follow-up scan. Comparisons between the whole group before and after treatment showed a significant improvement in FP-CIT uptake in both caudate and putamen ($p<0.001$ in each nucleus). Putamen to caudate ratio and asymmetry indexes did not show a significant difference before and after treatment. Discussion. We found although in a small study population a DAT overexpression after a chronic treatment with rotigotine presumably related to its pharmacological profile. The DAT upregulation by rotigotine with an opposite direction with respect to early PD compensatory mechanisms might reduce the risk of dyskinesia, but it could imply a less motor benefit because of a less stimulation by dopamine itself on dopaminergic receptors.

PW04 - Sunday, October 11, 2015, 8:30 AM - 9:30 AM, Hall 3 – Poster Exhibition

PW031

The role of 68Ga-DOTATATE PET/CT imaging in the decision of Peptide Receptor Radionuclide Therapy (PRRT) administration

E. Skoura[1], S. Michopoulou[1], O. M. AlMukhalid[1], E. Panagiotidis[1], M. Al Harbi[1], I. Kayani[1], R. Syed[1], P. J. Ell[1], M. E. Caplin[2], J. Bomanji[1]; [1]UCLH, London, UNITED KINGDOM, [2]Royal Free Hospital, London, UNITED KINGDOM.

Aim: Peptide receptor radionuclide therapy (PRRT) consists of the systemic administration of a synthetic peptide, labeled with a suitable β-emitting radionuclide, able to irradiate tumors and their metastases. PRRT, with either 90Y-octreotide or 177Lu-octreotate, has established to be an efficient and effective therapeutic

modality that provides objective responses in neuroendocrine tumors (NET), and is well tolerated with moderate toxicity. This study was performed to reveal if 68Ga-DOTATATE PET/CT can influence the decision of PRRT administration in NET patients.Materials ad Methods: Data from patients with NET who received PRRT or were candidate for PRRT were analyzed.Results: Between May of 2005 and August of 2013, 1246 68Ga-DOTATATE PET/CT scans were performed in patients with confirmed or suspected NET. In 13.4% of these cases (in 167 cases), radioisotope therapy, either as PRRT- 177Lutetium (177Lu)-DOTATATE and 90Yttrium (90Y)-DOTATOC- or 131I-MIBG was received after 68Ga-DOTATATE PET/CT scans. In this patient group, PRRT was decided as new treatment in 85 cases (6.8% of the total cases). In these 85 cases, 68Ga-DOTATATE PET/CT imaging showed extensive unresectable and/or metastasized disease with intense 68Ga-DOTATATE uptake. In two cases (0.2%) the PRRT was rejected as treatment because of the low tracer uptake. In detail, 177Lu-DOTATATE was administrated in 46 cases, 90Y-DOTATOC in 25 cases, while in 14 cases the given radiopharmaceutical for PRRT is not known to us (177Lu-DOTATATE or 90Y-DOTATOC). Finally, in 4 cases treatment with 131I-MIBG was decided, as the MIBG uptake in diagnostic 123I-MIBG scan, was more intense that the 68Ga-DOTATATE uptake in 68Ga-DOTATATE PET/CT scan.Conclusion: PRRT is established treatment in patients with advanced and/or progressive NET and 68Ga-DOTATATE PET/CT imaging is necessary prior PRRT to target the somatostatin receptors. Our study reveals that PRRT could be decided as new treatment in a significant percentage of NET patients, when 68Ga-DOTATATE PET/CT scan shows extensive unresectable and/or metastasized disease with intense uptake.

PW032

Radioguided laparoscopic surgery of occult colonic lesions

G. Manca[1], G. Boni[1], R. Spisni[2], S. Chiacchio[1], S. Mazzarri[1], E. Tardelli[1], M. Biricotti[2], D. Volterrani[1]; [1]Regional Center of Nuclear Medicine, Pisa, ITALY, [2]Department of Surgery, University of Pisa, Pisa, ITALY.

Introduction: intraoperative localization, during laparoscopic surgery, of small occult colonic lesions situated in particular areas and/or with concomitant inflammatory bowel disease, such as diverticulosis, perivisceritis, etc., can be problematic. We investigated the feasibility of radioguided occult colonic lesion identification during laparoscopic surgery after an adequate phase of preoperative labelling. Subjects & methods: patients presenting with colonic lesions difficult to detect for their size and location were considered eligible for our study. These patients were first submitted to coloscopy on the same day or 24 hours prior to surgery, in order to administer the radiopharmaceutical into the submucosal layer around the colonic lesion. At least two injections (each containing an activity of 20-40 MBq in a volume of 2 ml) of 99mTc-labelled albumin macroaggregates were administered through a disposable sclerosing syringe around the lesion. During surgery the search for the radiolabelling colonic lesion was carried out by a 11-mm orthogonal-view wireless laparoscopic gamma-detection probe. The site of the lesion was marked with a clip or with a suture. The pathologic features of the lesion determined the type and extension of the surgery to be adopted for each patient. Results: a total of nine colonic lesions, one for each of nine patients, were appropriately marked before surgery and were all intraoperatively detected by laparoscopic gamma-detection probe (identification rate = 100%). According to the surgeon's opinion, this method to detect the colonic lesion was technically feasible, rapid, safe and efficient, and no lengthy learning curve was necessary. Conclusion: our study demonstrates that preoperative endoscopic radiolabelling of occult colonic lesions by injecting 99mTc-labeled albumin macroaggregates followed by surgical detection with a dedicated laparoscopic gamma probe is an accurate, efficient and useful clinical approach, also safe both for the patient and the medical staff in the operating room.

PW033

Is K-ras mutation affecting 18F-FDG uptake in colorectal cancer?

A. Ozen[1], M. Tokocin[1], E. Namal[2], E. Gokmen[1], T. Vartanoglu[1], F. Celebi[1]; [1]Bagcilar Training and Research Hospital, Istanbul, TURKEY, [2]Istanbul Bilim University, Istanbul, TURKEY.

AimThe colorectal cancer (CRC) is the third most common cancer worldwide and the fourth leading cause of cancer-related mortality. Current metastatic CRC therapy uses monoclonal antibodies such as cetuximab against the epidermal growth factor receptor pathway that regulates cell survival, motility and proliferation, as well as angiogenesis and metastasis. This treatment is only useful in the absence of K-ras gene mutations. The aim of our study was whether K-ras mutation affects 18F-FDG uptake in colorectal cancer.Materials and methodsThis study included 10 male (mean age: 52.2±17.21) and 7 female (mean age: 49.14±13.88) patients with CRC. The stages of patients were I in 1(5.9%), IIA in 1(5.9%), IIIB in 1(5.9%), IVA in 9 (52.9%), and IVB in 5 patients (29.4%). The K-ras mutation status was mutant in 5 patients and wild in 12 patients. Furthermore, the patients divided two groups according to CEA level at diagnose time as high at ≥50 and low at

<50. The 18F-FDG PET/CT study was performed preoperatively in all patients. The SUVmax was calculated from images at 1-hour (SUV1) and 3-hours (SUV2) after i.v. injection of 18F-FDG. Furthermore, retention index (RI) was calculated in 11 patients following formula; RI=100 x (SUV2-SUV1) / SUV1.ResultsThe SUV1, SUV2 and RI in K-ras mutant patients were 9.448±3.247, 9.16±0.878, and 27.32%±1.56%, respectively. These values in K-ras wild patients were 13.545±6.054, 21.69±9.99, and 43.89%±16.57%, respectively. There was no statistically difference between K-ras mutant and wild patients for SUV1 (p:0.140), SUV2 (p:0.066), and RI (p:0.221). According to CEA level, There was no statistically difference between high value and low value for SUV1 (p:0.923), SUV2 (p:0.855), and RI (p:0.465).ConclusionWe found that K-ras gene mutation was not affected 18F-FDG uptake in CRC. But, our study included a small number of patients. We thought that there is need for additional research in large series of patients.

PW034

Evaluating the risk of postoperative liver failure using preoperative 99mTc-GSA SPECT/CT fused imaging

M. Yoshida[1], S. Shiraishi[2], N. Tsuda[2], F. Sakamoto[2], S. Tomiguchi[3], T. Beppu[4], H. Baba[4], Y. Yamashita[2]; [1]Amakusa Medical Center, Amakusa, JAPAN, [2]Department of Diagnostic Radiology, Graduate School of Life Sciences, Kumamoto University, Kumamoto, JAPAN, [3]Department of Diagnostic Medical Imaging, School of Health Faculty of Life Sciences, Kumamoto University, Kumamoto, JAPAN, [4]Department of Gastroenterological Surgery, Graduate School of Life Sciences, Kumamoto University, Kumamoto, JAPAN.

Aim: Evaluating the risk of postoperative liver failure is important for safe hepatectomy. Liver Uptake Value (LUV) calculated from preoperative 99mTc-GSA SPECT/CT fused imaging is useful for evaluating functional reserve of remnant liver. Therefore we compared the LUV indices with preoperative clinical risk factors of postoperative liver failure. Methods: We enrolled 560 patients (mean age 66.5±10.6 years) who were performed 99mTc-GSA SPECT/CT before hepatectomy. According to the ISGLS criteria, 27 of 560 patients showed postoperative liver failure. From 99mTc-GSA SPECT/CT, we calculated whole liver LUV and remnant LUV. The cut off value of two indices were calculated from ROC analysis. Older age (>70 years), portal vein hypertension, hepatitis, severe fibrosis, massive bleeding (>700ml), and postoperative complication (> grade 3 of Clavian Dindo classification) were decided as clinical risk factors. Results; The odds ratios of various indices were as follows; low remnant LUV (OR: 18.4; 95%CI: 3.9 - 70.5), low whole liver LUV (OR 4.7; 95%CI 2.0 - 10.9), hepatitis (OR 2.7, 95%CI 0.8 - 9.1), older age (OR 1.2, 95%CI 0.5 - 2.8), portal vein hypertension (OR 2.5, 95%CI 1.1 - 5.7), severe fibrosis (OR 4.4, 95%CI 1.7 - 11.2), massive bleeding (OR 2.7, 95%CI 1.2 - 6.1), and postoperative complication (OR 15.7, 95%CI 6.2 - 39.7). The odds ratio of combination low remnant LUV and low whole liver LUV was 19.9 (95%CI 6.8 - 58.5) and low remnant LUV and postoperative complication was 41.2 (95%CI 17.1 - 99.1). Conclusion; LUV indices calculated from 99mTc-GSA SPECT/CT fused image obtained before hepatectomy were useful for evaluating the risk of postoperative liver failure.

PW035

Can Potassium Perchlorate and Sodium Iodine influence Iodine-131 uptake in Cholangiocarcinoma?

A. F. Brito[1], T. Puga[1], R. Teixo[2,3], A. Fernandes[2,4,5], A. F. Brito[2,4,3], A. M. Abrantes[2,4,3], **L. F. Metello**[1,6], J. G. Tralhão[2,4,7], M. F. Botelho[2,4,3]; [1]Nuclear Medicine Department, High Institute for Allied Health Technologies, Polytechnic Institute of Porto, Vila Nova de Gaia, PORTUGAL, [2]Biophysics Unit, Faculty of Medicine, University of Coimbra, Coimbra, PORTUGAL, [3]CNC.IBILI, Faculty of Medicine, University of Coimbra, Coimbra, PORTUGAL, [4]Center of Investigation on Environmental, Genetics and Oncobiology (CIMAGO), Faculty of Medicine, Coimbra, PORTUGAL, [5]Gastroenterology Department, CHUC, Coimbra, PORTUGAL, [6]Nuclear Medicine Department, IsoPor SA, Ermesinde, PORTUGAL, [7]Surgical Department, Surgery A, CHUC, Coimbra, PORTUGAL.

Aim: Cholangiocarcinoma (CC) is a malignancy with poor prognostic, high mortality and limited treatment options, reason why the development of novel treatment strategies by exploiting new targets might be considered as consensually relevant. In fact, it was shown that CC expressed the sodium iodine symporter (NIS), which is responsible for iodine uptake by the cells. NIS is also the responsible for the uptake of iodine-131 (131I) in thyroid tumor and benign diseases, enabling the metabolic radiotherapy and opening possibilities of new treatment approaches for CC.Aim: This work aims to study the uptake profile of 131I mediated by NIS, in two human CC cell lines from distinct origins. The uptake specificity was tested using NIS inhibitor potassium perchlorate (KClO4) as well as the effect of sodium iodide (NaI) on 131I uptake.Material and Methods: Two human CC cell lines were used: TFK-1 from extra-hepatic CC and HuccT1 from intrahepatic CC. In order to study the

131I uptake profile, we incubated 2 x 106 cells/mL with 9.25 x 105 Bq of 131I for 120 minutes. During this period, several samples were collected and the respective counts per minute (CPM) registered. Furthermore, the NIS specificity for 131I was assessed in the presence of the inhibitor KClO4. For this purpose, the cells were pre-incubated with KClO4 (1 to 100μM) for 0, 30 and 60 minutes before adding 131I. The effect of NaI was tested using same protocol and same concentrations. The uptake of 131I was measured after 30 minutes incubation with the radiopharmaceutical.Results: It was observed 131I uptake in both cell line cell lines (TFK-1 and HuccT1). The uptake peak was between 5 and 30 minutes, remaining stable after that. Moreover, KClO4 reduced the NIS mediated 131I uptake levels, in both cell lines, when introduced in culture medium at the same time, suggesting that 131I uptake is dependent of plasma membrane functional NIS proteins. Preliminary results showed no differences in the 131I uptake, in both cell lines, when different stable iodine concentrations are present in the medium.Conclusions: Different types of human CC cell lines have the capacity to accumulate 131I, based on plasma membrane functional NIS expression. However the uptake is not influenced by the presence of NaI. These preliminary results seem to show the potential that metabolic radiotherapy with 131I could have for CC treatment.

PW036

Clinical Value of Metabolic Parameter for Evaluation of LN Metastasis in Clinical N0 Gastric Cancer

S. Choi, S. Lim, C. Na, J. Kim, Y. Han, H. Jeong, M. Sohn; Chonbuk National University Medical School and Hospital, Jeonju, Jeonbuk, KOREA, REPUBLIC OF.

Purpose: Predicting lymph node metastasis in gastric cancer has the crucial role because its possibility to changing therapeutic method either endoscopic resection or surgical gastrectomy. Preoperative CT scan has the limit to evaluate LN metastasis, which depends on size and shape, anatomically. The purpose of the study is to evaluate regional LN status by primary gastric tumor using its metabolic standardized uptake value (SUVmax) in radiologic No gastric cancer. Material and methods: We retrospectively reviewed 201 patients which were confirmed as gastric cancer from July 2012 to December 2012. All patients had done preoperative F-18 FDG PET/CT. Among the various histological gastric tumors, only adenocarcinoma showing FDG uptake evidently on PET scan is evaluated because of its accessability to measure metabolism. Among 201 patients, ninety-three patients (M : F= 61 : 32, age: 60.0 ± 12.3 yrs) show no discernible or below 0.6 cm sized regional LNs in preoperative CT scan, also having no FDG uptake which was interpreted as N negative. Dividing by two groups, 37 patients have pathologically confirmed as N positive and 56 patients have the result of N negative. Statistical analysis is performed by using student T-test and ROC curves to compare primary tumor SUVmax between two groups. Result: The mean values of SUVmax for pathologically confirmed as N positive and N negative groups are 7.39±3.4 and 5.77±2.5 each. There is significant difference between the two groups (P= 0.01). The cut-off value of SUV max in predicting LN metastasis is above 5.56. The other 69 of 201 patients, except above 93 patients, presenting FDG uptake in regional LN show high FDG uptake in primary gastric tumor, mean SUVmax= 11.91±6.7. Conclusion: The result shows higher FDG uptake in primary gastric tumor with LN metastasis than that of without LN metastasis. Furthermore, primary gastric tumor metabolism is much higher in the group which shows FDG uptake in regional lymph node. To clarify the correlation of FDG-avid LN with the other various factors, further studies should be needed. Predicting LN metastasis by means of measuring primary tumor metabolism could be the ancillary option to decide therapeutic plans in gastric cancer patients.

PW037

Comparative Analysis of Metabolic Response to Clinical Outcome in Metastatic Pancreatic Adenocarcinoma following Modified Dose Folfirinox.

A. Boustani[1], V. Patel[1], X. Cong[2], I. Doddamane[1]; [1]Yale University School of Medicine, New Haven, CT, UNITED STATES, [2]Yale University School of Public Health, New Haven, CT, UNITED STATES.

Aim: To compare early metabolic response with clinical progression free survival (PFS) and overall survival (OS) in patients with metastatic pancreatic adenocarcinoma following attenuated dose FOLFIRINOX. Methods: Of the 43 patients enrolled in the study between 11/2011 and 01/2014 29 patients were evaluated by both baseline and follow-up F18-FDG PET/CT. Medical reasons and technical issues limited accurate evaluation by F18 FDG PET/CT. 14 of the patients were excluded. A baseline PET/CT scan was obtained before treatment. It was followed by a second PET/CT after two cycles of chemotherapy with modified dose Folfirinox. Based on SUV max corrected for background, metabolic response of the lesions was categorized as stable, mild, significant, or as progression. Using Chi square test, Fisher's exact test, and Kaplan-Meier methods, PFS and OS were associated with PET response. Results: There were a total of 105 primary and metastatic lesions in 29 patients. 24 patients responded, 3 progressed, and 2 were stable. 5 patients did not respond.

Clinically, 24 of 29 patients were associated with PET response. 14 of 29 patients had significant response (48%, metabolic change by >50%). For statistical analysis, patients were also grouped as responders (83%, metabolic response by >25%) and non-responders (17%, metabolic response <25%). There was no association between PFS and OS and overall metabolic response (0.42 for both). Conclusion: An attenuated dose of Folfirinox was used for the treatment of metastatic pancreatic cancer in order to evaluate its efficacy while improving its tolerability. There was a high percentage of metabolic response at follow-up (83%). However, this did not correlate with clinical outcome. Larger sample sizes are required for further evaluation.

PW038

Role of FDG-PET/CT in predicting response to neoadjuvant therapy in esophageal cancer. Correlation with pathological response and survival. Preliminary study.

J. J. Robles-Barba[1], C. Gámez-Cenzano[1], J. L. Vercher-Conejero[1], A. Sabaté-Llobera[1], M. Cortés-Romera[1], L. Rodríguez-Bel[1], L. M. Gràcia-Sánchez[1], F. Martínez-Torrens[2], R. Mast-Vilaseca[2], M. J. Paules-Villar[3], M. Miró-Martín[4], A. M. Boladeras-Inglada[5], M. Calvo-Campos[6], M. Galán-Guzmán[6]; [1]PET-CT Unit, Institut de Diagnòstic per la Imatge (IDI). Bellvitge Hospital., L'Hospitalet de Llobregat, SPAIN, [2]Radiología. Bellvitge Hospital., L'Hospitalet de Llobregat, SPAIN, [3]Anatomía Patológica. Bellvitge Hospital., L'Hospitalet de Llobregat, SPAIN, [4]Cirugía General. Bellvitge Hospital., L'Hospitalet de Llobregat, SPAIN, [5]Oncología Radioterápica. Institut Català d'Oncologia, L'Hospitalet de Llobregat, SPAIN, [6]Oncología Médica. Institut Català d'Oncologia, L'Hospitalet de Llobregat, SPAIN.

AIM: To assess the correlation between metabolic response with FDG-PET/CT and pathological response in patients with locally advanced esophageal cancer treated with neoadjuvant chemoradiotherapy, and to study FDG-PET parameters for prediction of pathological response and outcome. MATERIAL AND METHODS: Twenty-five patients (22 male; age range 45-79 y.o) with locally advanced esophageal cancer (stage III; 10 squamous cell and 15 adenocarcinoma) underwent 2 FDG-PET/CT scans at 2 time points: 1(Initial staging and 2) 4 weeks after neoadyuvant chemoradiotherapy. FDG uptake in the primary tumor was calculated in the 2 scans with the following parameters: SUVmax, SULpeak and TLG. Metabolic response was assessed according to the reduction of PET parameters (%): complete response (mCR=100%), partial response (mPR≥50%) and no response (≤50%). Pathological response obtained after surgery, was also classified as complete (pCR), partial (pPR) or no response (pNR). Patients were followed up (range 8 - 99 months) determining free-disease interval (FDI) and overall survival (OS). RESULTS: Two patients were excluded of our study due to exitus for non-esophageal related causes. Metabolic response was observed in 18 of the 23 remaining patients (3 mCR and 15 mPR), of which 12/18 patients showed pathological response (3 pCR and 9 pPR). Major discrepancy was observed in 2 of PET non-responders patients (5) who achieved pPR. FDI and OS were apparently longer in patients with metabolic response than non-responders (18,5 and 28 months vs 12 and 20 months) but no statistical difference was found in this small group. No significant correlation was found between PET parameters (including the % of reduction) and the pathological response, FDI and OS. CONCLUSION: FDG-PET/CT is a useful technique to assess response to neoadjuvant chemoradiotherapy in esophageal cancer. Althoug in this preliminary study with a small number of patients, no correlation between metabolic and pathologic response was found and no statistical differences between responders and non-responders were observed, a tendency of a longer FDI and OS was apparently found in responders patients.

PW039

Maximum standardized uptake value on FDG PET is associated with overall survival in limited-stage small cell lung cancer

S. Lee[1], S. Kwon[1], S. Hyun[2], Y. Oh[1], J. Choi[1], K. Park[1]; [1]Ajou University School of Medicine, Suwon, KOREA, REPUBLIC OF, [2]Sungkyunkwan University School of Medicine, Seoul, KOREA, REPUBLIC OF.

Aim: We evaluated the prognostic value of ^{18}F-fluorodeoxyglucose positron emission tomography (FDG PET) parameters for limited-stage small-cell lung cancer (LS-SCLC). Materials and Methods: We enrolled 59 LS-SCLC patients who underwent pretreatment FDG PET/CT. Various PET parameters were measured in all malignant lesions, and we recorded the highest maximum standardized uptake value (SUV_{max}), and sum of metabolic tumor volume (MTV_{sum}) and total lesion glycolysis (TLG_{sum}). The relationship between SUV_{max} and volumetric PET parameters was evaluated. The prognostic significances of PET parameters and clinical variables were assessed using Cox's proportional hazard regression analysis. Overall survival (OS) and progression-free survival (PFS) were assessed by the Kaplan-Meier method. Results: The SUV_{max} of the highest metabolic lesion had a significant positive correlation with MTV_{sum} and TLG_{sum} ($P < 0.0001$). Upon multivariate analysis, SUV_{max} was an independent predictor of OS (HR: 1.133, $P = 0.003$) and MTV_{sum} was a significant prognostic factor of PFS after

adjusting for age, sex, performance status, tumor stage, and treatment modality. SUV_{max} tended to be a significant prognostic factor for PFS (HR: 1.078, $P = 0.053$). Patients with higher SUV_{max} (≥11) were also characterized by a significantly shorter median OS ($P = 0.0001$) and PFS ($P = 0.0017$) compared with patients with lower SUV_{max}. Conclusion: The highest SUV_{max} is an independent prognostic factor for survival in LS-SCLC patients.

PW040

The correlation between 18F-FDG uptake and Glut-1, Stat-1 and Stat-3 in non-small cell lung cancer patients.

H. Kaida[1], K. Azuma[2], A. Kawahara[2], S. Hattori[2], S. Takamori[2], E. Sadashima[2], K. Fujimoto[2], M. Kage[2], S. Kurata[2], Y. Hirose[2], K. Ishii[1], T. Murakami[1], M. Ishibashi[3]; [1]Kinki University Faculty of Medicine, Osakasayama City, JAPAN, [2]Kurume University School of Medicine, Kurume City, JAPAN, [3]Fukuoka Tokushukai Hospital, Kasuga City, JAPAN.

Aim. The purpose of this study was to assess the correlation between 18F-fluorodeoxyglucose (18F-FDG) uptake and glucose transporter-1 (Glut-1), signal transducer and activator of transcription-1 (Stat-1) and Stat-3 expression in completely surgically resected non-small cell cancer (NSCLC) patients. Materials and Methods. Our patients consisted of 52 patients [31 men and 21 women]. The median age of these patients was 72.5 (range, 42-91) years. The patients with tumors diameter less than 10 mm and the patients who underwent neoadjuvant chemotherapy before surgery were excluded from this study. Histopathologically, there were 38 adenocarcinomas and 14 squamous cell carcinomas. The clinical stages of all patients were as follow: stage IA (n=27), IB (n=8), IIA (n=7), IIB (n=6) and IIIA (n=4). 18F-FDG positron emission tomography (PET) was performed, and the maximum standardized uptake value (SUV max) of primary tumor was measured. Pathological tumor size was estimated by measuring the maximum diameter of the tumor, and pathological TNM staging was determined after operation. Excised tumor tissue was analyzed immunohistochemistry using monoclonal antibodies for Glut-1, Stat-1, and Stat-3. Spearman's rank correlation test and Kruskal-Wallis test were performed to assess any association between 18F-FDG uptake and each histopathlogical or immunohistochemical factor. Results. The median value of SUV max of primary tumor was 4.76 (range 0.83-15.39). The median value of immunohistochemistry staining for Glut-1, Stat-1 and Stat-3 was 30% (range, 0-80%), 1% (range, 0-15%) and25% (range, 0-70%), respectively. SUV max positively correlated with Glut-1 expression (r=0.685, P<0.001) and Stat-1 expression (r=0.295, P=0.03). SUV max inversely correlated with Stat-3 expression (r=-0.579, P<0.001). Glut-1 positively correlated with Stat-1 expression, however, inversely correlated with Stat-3 expression [r=0.35, P=0.01, Stat-1, r=-0.377, P=0.006]. Pathological tumor size positively correlated with SUV max (r=0.327, P=0.018) and Glut-1(r=0.54, P<0.001), however inversely correlated with Stat-3(r=-0.318, P=0.022). High SUV max tended to be advanced pathological T stage (P=0.01), pathological lymph node metastasis (P=0.015) positive and advanced pathological Stage (P=0.024). Conclusion. Glut-1 expression, Stat-1 and Stat-3 may be associated with SUV max of primary tumor. High Glut-1 and Stat-1 expression, low Stat-3 expression and cellularity may be related with high 18F-FDG uptake in NSCLC.

Poster Walk 5 - Physics & Instrumentation & Data Analysis: Data Analysis & Management

PW041

Development of a new quantification method using the I-123 MIBG myocardial single photon emission tomography

Y. Kamiya[1,2], S. Okumiya[1], A. Takaki[3], K. Yamashita[3], S. Ito[1]; [1]Kumamoto University, Kumamoto, JAPAN, [2]Chibana Clinic, Okinawa, JAPAN, [3]Fujifilm RI Pharma Co.,Ltd., Tokyo, JAPAN.

[Objective]Iodine-123 metaiodobenzylguanidine (^{123}I-MIBG) myocardial scintigraphy has been used to evaluate cardiac sympathetic denervation in Lewy body disease (LBD) including Parkinson's disease (PD) and dementia with Lewy bodies (DLB). The heart-to-mediastinum ratio (H/M) in PD and DLB is significantly low compared to that in Parkinson's plus syndromes (PPS) and Alzheimer's disease (AD). The H/M is useful for distinguishing LBD from AD. However, the distinction of AD and the PPS is difficult due to narrow H/M range. Additionally, accuracy of this method is limited, as the H/M is obtained by a two-dimensional image analysis. Therefore, a new quantification method using the ^{123}I-MIBG single photon emission tomography (SPECT) image analysis is required for clinical routine study in order to guarantee repeatability and reproducibility. The purpose of this study was to develop a new quantification method with a simple determining protocol for ^{123}I-MIBG SPECT uptake measurement.[Materials and methods]The ^{123}I-MIBG input function was obtained by using integrated lung washout ratio and the input counts of the

pulmonary artery (PA). These were obtained by analyzing the time activity curve of the lung and PA. The ^{123}I-MIBG output function was obtained by using the ^{123}I-MIBG SPECT counts on the polar map. The uptake was obtained by dividing the output function by the input function.Thirty-nine patients underwent ^{123}I-MIBG SPECT at 15 min after the tracer injection and clinical features such as Hoehn and Yahr (H-Y) classification. The H/M and the uptake of ^{123}I-MIBG were calculated, and correlation with the clinical features was analyzed.[Result]The H/M of LBD (median 1.75) was significantly lower than in PPS (median 2.85, $p<0.01$). The discretion of AD (median 2.65) and PPS (median 2.85) was impossible. The uptake of LBD (median 2.09%) obtained by the new method was significantly lower than in PPS (median 7.94%, $p<0.01$). The uptake ratios of AD (median 5.62%) was significantly lower than in PPS (median 7.94%, $p<0.05$).[Conclusion]The new quantification method was developed by using ^{123}I-MIBG SPECT and integrated lung washout ratio and the input counts of the PA. The AD, LBD and PPS can be clearly distinguished by using this method. This finding indicates the possibility of clinical routine study.

PW042

Application of Novel Phase Parameters for Characterisation of Ventricular Mechanical Dyssynchrony with Radionuclide Ventriculography

K. Jones, N. E. R. Goodfield, J. Robinson, W. Martin, C. A. Paterson; NHS Greater Glasgow and Clyde, Glasgow, UNITED KINGDOM.

Aim: Assessment of left ventricular function is known to be a powerful prognostic indicator of cardiovascular disease. Synchrony (S), entropy (E) and sample approximate entropy (SampEn) are novel indices to characterise dyssynchrony, which have been shown to give additional independent prognostic information. Synchrony is a measure of ventricular contraction coherence and entropy describes the degree of randomness of ventricle phase disorder. SampEn is a measure of entropy which takes into account regional phase similarly of adjacent pixels. The aim of this study is to establish a normal range of synchrony, entropy, SampEn, the correlation of each parameter with ejection fraction (EF) and their ability to discriminate between normal studies and those with mechanical dyssynchrony. Methods: 526 clinical gated planar list-mode RNVG studies were retrospectively re-analysed using in-house software. The studies analysed consisted of 250 normal studies (QRS < 120 ms, normal myocardial perfusion scan, normal RNVG scan, normal EF), 164 with myocardial infarction (MI), 112 with left bundle branch block (LBBB). Synchrony, entropy and SampEn were calculated from phase information extracted from the first order Fourier harmonic fit to the RNVG time-activity curve. Results were analysed using receiver operating characteristic analysis (ROC) and area under the ROC curve (AUC) values were obtained. Results and Conclusion: Synchrony and entropy values were found to be significantly different when comparing normals with both MIs and LBBBs ($p < 0.005$). SampEn values were significantly different between normals and MIs but not between normals and LBBBs ($p=0.1$). Overall good diagnostic accuracy was found for detection of MIs based on dyssynchronous ventricular contraction; AUC = 0.79 for S, AUC = 0.86 for E and AUC = 0.70 for SampEn. Correlation with ejection fraction was R = 0.67 for S, R = -0.72 for E and R = -0.52 for SampEn. This study has established the normal range for synchrony, entropy and SamEn for a large cohort of normal studies and demonstrated their potential for quantifiable assessment of ventricular function. Future work will optimise and further characterise these parameters. The MI group will be further sub-categorised by size and alternative metrics for mechanical dyssynchrony will also be assessed.

PW043

Improved scatter correction applying factor analysis

P. Knoll[1], M. Ljungberg[2], S. MIrzaei[1], M. Samal[3]; [1]Wilhelminenspital, VIenna, AUSTRIA, [2]Department of Medical Radiation Physics, Clinical Sciences, Lund University, Lund, SWEDEN, [3]Department of Nuclear Medicine, First Faculty of Medicine, Charles University, Prague, CZECH REPUBLIC.

Aim: Obtaining quantitative data is a crucial task in nuclear medicine. In order to achieve this goal the various interactions of photons with matter have to be observed, modelled and considered. A problem in gamma camera imaging is the inclusion of scattered photons within the photopeak energy window used for acquisition. Many methods for scatter correction have been proposed in the past but in this work we use a novel setup applying factor analysis (FA). **Material and Methods**: Monte Carlo simulations using the SIMIND software package were used to simulate planar (99m Tc point source, 99m Tc MDP bone) and tomographic acquisitions. Furthermore a Jaszczak phantom study and patient 99m Tc MDP bone studies were performed using a large-field of view gamma camera. In order to use FA for scatter correction we subdivided the applied energy window in 28 simultaneous sub-windows which serves as input data. The Jaszczak phantom was acquired using General Electric's Infinia Hawkeye (acq. parameters: 360° SPECT, 6°/frame, 40 sec./frame) using the same number of sub-energy windows. The

tomographic data (simulation and measurement) were processed for each angular position resulting in a photopeak and a scatter data set. The reconstructed transaxial slices were quantified using an ImageJ plugin. **Results**: FA results in two factor images (photopeak, scatter) and two factor curves. The data obtained by factor analysis showed good agreement with the simulated energy spectra, photopeak and scatter images obtained by Monte Carlo simulation for all simulated data sets. The cold sphere contrast of the Jaszczak phantom applying no scatter correction ranges from -47.67 to -4.75 and with scatter correction applying FA from - 51.48 to -7.52. The cold sphere sector contrast ranges from -16.61 to -0.18 for the non-scatter corrected data and for the FA data from -16.61 to -0.23. **Conclusion**: Factor analysis can be used as a user-independent approach for scatter correction for planar and tomographic imaging.

PW044

Quantification of striatal uptake in DaTscan dopamine transporter imaging: Effect of systematically reduced count density on diagnostic accuracy

C. Paterson, J. Robinson, S. Smith, W. Martin; Glasgow Royal Infirmary, Glasgow, UNITED KINGDOM.

Outline and Aims: [^{123}I]-FP-CIT (DaTscan) is a radioligand developed for the imaging of dopamine transporters with SPECT. Its use as an in-vivo pre-synaptic imaging agent to detect degeneration of the dopaminergic nigrostriatal pathway and to characterize Parkinson's Disease (PD) has been well established. Quantification of striatal uptake has the potential to further increase diagnostic accuracy and reduce the number of equivocal reports. Increases in numbers of referrals and difficulties with subject tolerance of long imaging times has prompted consideration of reducing the administered activity and/or acquisition time. This study aims to investigate the effect that simulating a reduction in administered activity has on the quantification of the striatal specific binding ratio (SBR) and its diagnostic accuracy. Methods: 85 clinical studies (44 positive for PD based on a surrogate gold standard of previous clinical interpretation) were retrospectively re-analyzed. Reduction in administered activity to 75%, 66%, 50% and 25% of the original activity was simulated by reducing the number of counts in every pixel of the raw data projections. A Poisson noise generator was then used to add an appropriate level of statistical noise back into each image. Once the data were transformed to the reduced count densities two experienced operators independently reconstructed, processed and analysed each image for calculation of SBR.Results: The SBR technique for calculation of striatal uptake was found to have excellent inter-operator reproducibility at all count densities ($R > 0.92$; Bland-Altman bias < 1.19 and limits of agreement < 1.62) and there was excellent correlation between the SBR values calculated at the different count densities for both operators ($R > 0.94$; Bland-Altman bias < 0.47 and limits of agreement < 1.92). Furthermore, receiver operating characteristic analysis (ROC) found no significant change in the area under the ROC curve (AUC) for each count density (AUC > 0.84).Summary: Overall, the study proves the robustness of the SBR quantification technique at reduced count densities both in terms of the diagnostic accuracy of the technique and the inter-operator variability. This gives confidence that [^{123}I]-FP-CIT imaging with quantification can be performed with reduced administered activities (or reduced acquisition times). Further work will assess how visual clinical assessment of the images is affected by reduced activity, and whether or not diagnostic performance at low count densities can be improved through the use of advanced reconstruction algorithms and machine learning based interpretation.

PW045

Statistical variance in standardised striatal uptake ratio in [123I]FP-CIT SPECT imaging

A. Niñerola-Baizán[1,2], J. Gallego[2], A. Cot[1,2], F. Lomeña[3,4], D. Ros[1,2], J. Pavía[1,3]; [1]Centro de Investigación Biomédica en Red en Bioingeniería, Biomateriales y Nanomedicina (CIBER-BBN), Barcelona, SPAIN, [2]Unitat de Biofísica i Bioenginyeria, Facultat de Medicina, Universitat de Barcelona, Barcelona, SPAIN, [3]Servicio de Medicina Nuclear, Hospital Clínic, Barcelona, SPAIN, [4]Centro de Investigación Biomédica en Red de Salud Mental (CIBERSAM), Barcelona, SPAIN.

INTRODUCTION: [123I]FP-CIT SPECT is a widely used tool for the in vivo evaluation of the dopaminergic system in movement disorders including Parkinson's disease (PD). To objectively assess striatal dopamine transporter (DaT) binding, a semi-quantitative analysis including standardisation is recommended. Standardisation enables us to compare the findings from multicentre trials and to generate a comprehensive reference database. However, uptake quantification and standardisation depend on noise in projections and reconstruction parameters. AIM: To determine the reconstruction parameters and postfilters that yield the minimum variance in the standardised results. MATERIALS AND METHODS: [123I]FP-CIT SPECT studies were simulated by using the SimSET Monte Carlo code. The activity maps were obtained from 3D T1-weighted MR images corresponding to 23 subjects free of cerebral abnormalities. The FIRST segmentation tool from FSL was used to select caudate and putamen nuclei from MR images. Specific Uptake Ratio (SUR) values between 1 and 10 for caudate and putamen were selected. Three million counts in projections were simulated. Reconstruction was performed using OSEM (8 subsets and 1 to 30 iterations) with attenuation correction, PSF correction and an

ideal scatter correction with only the primary photons in the simulated projections. Reconstructed images were filtered by using a set of Gaussian post-filters with FWHM of 0 (i.e. no post-filter), 2, 4, and 6 mm. SUR values were calculated using the MRI original ROIs. Standardised SUR values were obtained by applying the inverse of the regression line relating calculated to true SUR values. The linear regression analysis allowed us to evaluate the variance of the results by calculating the standard error of the estimate (SSy) and the Root Mean Square Deviation (RMSD) between standardised and true values. RESULTS: Small differences in the minimum RMSD value were found for all post-filters. Thus, the minimum of RMSD (0.239) was achieved at 13 iterations without post-filter, whereas RMSD was 0.225 at 30 iterations when a post-filter of 6mm FWHM was applied. The number of iterations diminished to 4 and 8, respectively, if differences of 5% between actual RMSD and RMSDmin were considered. The SSy value at 8 and 30 iterations with the 6mm FWHM post-filter was 0.238 and 0.226, respectively. CONCLUSIONS: Monte Carlo simulation allowed us to estimate the variance in standardised striatal uptake ratio due to methodology. A minimum RMSD of 0.225 and a SSy of 0.226 should be considered as the methodological error to be complemented with that caused by the physiological variability.

PW046

Is a system calibration required when using a I123-FP-CIT Normal Database?

J. C. Dickson[1], L. Tossici-Bolt[2], K. Tatsch[3]; [1]University College London Hospital NHS Foundation Trust, London, UNITED KINGDOM, [2]University Hospital Southampton NHS Foundation Trust, Southampton, UNITED KINGDOM, [3]EANM EARL ENCDAT Imaging Consortium, Vienna, AUSTRIA.

Introduction: Normal databases offer the potential of improving the diagnostic performance of imaging tests such as I123-FP-CIT. It has been suggested to make best use of an I123-FP-CIT database; there should be a reference calibration of a system to allow normal range values to be tailored to that particular system. This paper studies the diagnostic performance of a normal database with and without this reference calibration, and also assesses the possibility of replacing a bespoke calibration with an existing calibration for the same system type. Methods: The ENCDAT normal database was reconstructed using iterative reconstruction with corrections for attenuation and scatter as per the ENCDAT protocol [1]. Once reconstructed age dependent normal ranges of quantitative uptake were derived for a GE Infinia system on which 44 patient studies with three year follow-up information had been acquired. Normal ranges were defined using (1) a bespoke calibration of the system (BES), (2) an existing library calibration of the same system type (LIB), (3) no calibration for the imaging system (NO). Using three-year follow-up information as the gold-standard diagnosis, sensitivity and specificity of the different calibration strategies were calculated using striatal uptake as the diagnostic marker, and using putaminal uptake as the diagnostic marker. Results: With striatal uptake as a diagnostic marker there was no significant difference in sensitivity across the three strategies 85.7% (BES & LIB), 76.2% (NO). There was also no significant difference in specificity 87.0% (BES & NO), 78.2% (LIB). Similarly, when putaminal uptake was used as a diagnostic marker, there was no significant different between calibration strategies. Sensitivity was 85.7% (BES & NO), 90.5% (LIB), and specificity 82.6% (BES), 78.3% (LIB), and 87.0% (NO). Conclusions: In our single-site sample of 44 patients there was no diagnostic advantage to be gained from calibrating the system with either a bespoke or library calibration. PW047

The effect of different reconstructions algorithms on the diagnostic performance of a 123-FP-CIT SPECT database

J. C. Dickson[1], L. Tossici-Bolt[2], K. Tatsch[3]; [1]University College London Hospital NHS Foundation Trust, London, UNITED KINGDOM, [2]University Hospital Southampton NHS Foundation Trust, Southampton, UNITED KINGDOM, [3]EANM EARL ENCDAT Imaging Consortium, Vienna, AUSTRIA.

Introduction: The use of quantitative information from healthy control databases offers an improvement in the diagnostic performance of imaging tests such as I123-FP-CIT SPECT. However, it is not known how the use of different SPECT reconstructions affects the performance of these databases. The aim of this study was to explore this issue. Methods: The ENCDAT normal database [1] and patient data from 77 patients from two different centres and with three-year follow-up information were used in this study. All data was reconstructed using iterative reconstruction with corrections for attenuation and scatter (IRACSC), without corrections (IRNC), and with filtered back projection (FBP). Quantitative normal ranges using Hermes BRASS were set using the database for these reconstructions, with patient data normality assessed quantitatively on a striatal and putaminal level. Using clinical follow-up as our gold standard, sensitivity/specificity and ROC analysis were performed to assess the diagnostic accuracy of databases reconstructed in different ways. Results: Using striatal uptake as

a diagnostic marker, sensitivity was similar for different reconstructions at 83.7% (ACSC), 81.4% (IRNC) and 81.0% (FBP). Similarly specificity was not significantly different 85.3% (ACSC), 82.4% (IRNC) and 77.14% (FBP). ROC analysis confirmed that there was no significant difference in the diagnostic performance of the different reconstructions with AUC if 0.898 (ACSC), 0.913 (IRNC), and 0.880 (FBP). There were similar findings when putaminal uptake was used as a diagnostic marker with sensitivities of 81.4% (ACSC), 78.6% (IRNC), and 78.6% (FBP) and specificities of 82.4% (ACSC), 85.7% (IRNC), and 77.1% (FBP). ROC analysis derived AUC were 0.907 (ACSC), 0.917 (IRNC), and 0.893 (FBP). Conclusions: In our sample of 77 patients we found no significant difference in the diagnostic performance of a normal database using different reconstruction algorithms. PW048

Investigation of the Factors Affecting Quantification of Heterogeneity derived from PET Images of the Torso NEMA Phantom

M. Tamal, C. Robinson, D. Clarke, J. Anton-Rodriguez, D. Morris, A. Jackson, M. Asselin; The University of Manchester, UK, Manchester, UNITED KINGDOM.

Introduction: Radiotracer tumour uptake is often heterogeneous and quantification of heterogeneity has the potential to be used as a biomarker of prognosis. Textural features accounting for both spatial and intensity information have recently been applied to FDG-PET images and used to predict treatment response[1]. However, textural features have been predicted to strongly depend on volume using simulated data[2] and confirmed on clinical data[2],[3]. Other factors affecting textural features such as segmentation and quantization have previously been investigated on clinical data where the actual tumour volume is unknown[4] while image contrast and noise have not been assessed systematically. This study aims to investigate the relationships between textural features and these factors using phantom data.Methods: The torso NEMA phantom was filled with 18F solutions to yield different contrasts between the six hot spheres (0.5-27ml) and the colder uniform background (2:1, 4:1, 8:1) and scanned on the TrueV PET-CT scanner for 120min. Images were reconstructed using OSEM (4 iterations, 21 subsets) for different scan durations (15-120min) and smoothed with a 4-mm Gaussian filter. Spheres were first delineated at the exact boundaries based on their known diameters and secondly using a 40% fixed threshold. Textural features were derived from the co-occurrence matrix using different quantization levels (8-256).Results: Some textural features (contrast, dissimilarity, entropy, correlation) increase while others (homogeneity, energy) decrease with quantization at different rates depending on sphere volume. When using the exact delineation, contrast and scan duration (noise) have a lesser effect on textural features than sphere volume. When applying the same exact regions on the uniform background (no partial volume), the relationships between textural features and volume are comparable to when applied to the respective spheres except for correlation. On images with very low noise (120min) and high contrast (8:1), thresholded regions underestimate sphere volumes >5ml by ≈10% and thus yield textural features similar to those using the exact delineation. However, because larger thresholded regions are segmented as contrast is lowered, textural features become contrast dependent when using a fixed threshold.Conclusion: Homogeneous regions appear heterogeneous on PET images as quantified by textural features. Since textural features differentially vary with volume, regions should be segmented using methods that are robust to variations in contrast and noise and their volume reported.References:[1]Chicklore S. et al (2013) Eur.J.Nucl.Med.Mol.Imaging 40(1):133-40[2]Brooks F.J., Grigsby P.W. PW049

Quantification Challenges in Dual-Time PET Scans

T. Nguyen, S. B. Christlieb, P. F. Hoeilund-Carlsen; Dept. of Nuclear Medicine, Odense University Hospital, Odense, DENMARK.

Aim: Dual-time PET to detect temporal changes in a lesion depends on a reliable comparison of region-of-interests (ROIs) between time points. Commercial software tools like ROVER (ABX, Radeberg, Germany) require the user to encircle the analysis area with a mask, based on which a background corrected peak-based threshold is estimated for subsequent ROI (lesion) segmentation within the mask. The reliance on mask placement can thus introduce observer and segmentation variability, especially in heterogeneous tissue. If the same mask is used, mask-related variation between scans is minimized, but requires that the scans are spatially aligned. Hence, inevitable inter-scan patient movement necessitates image alignment procedures that use mathematical interpolation of image intensities to transform one image to spatially match another with the risk of altering the PET data. We evaluated these aspects for lymphoma assessment. Materials and

Methods: Dual-time (1h - 3h) FDG-PET scans of 14 patients (seven with malignancy, seven benign) were analyzed retrospectively. The ROVER software was used for ROI detection with background corrected global lesion-based (LT) and local voxel-based (VT) thresholds and rigid (translation/rotation operations only) image volume alignment. ROI detection to yield ROI values of SUV_{max}, SUV_{mean}, and metabolically active volume (MAV) was performed in two analyses: 1) Separate masks and segmentations of lesions (lymph node/conglomerate) in the 1h and 3h scans. 2) Same 1h mask also used for segmentation on the 3h scan after rigid alignment of the 3h scan to the 1h scan. Results: With separate masks, SUV_{max} in the 1h (mean ± sd: 18.2 ± 10.4) and 3h scans (23 ± 12.9) was reproducible, but SUV_{mean} and MAV varied between LT and VT methods. Here, all three measures showed intra-observer variation ≦ 18%. In the 3h scans, alignment procedures resulted in consistently significant changes in SUV_{max} (8.6% -21.8%) and SUV_{mean} (LT: 6.9%-23.4%, VT: 4.7%-44.4%) and variably significant MAV increases (LT: 0.2%-60%, VT: 5.4%-71.3%). Measured with separate masks, SUV_{max} and SUV_{mean} generally increase significantly between scans ($p < 0.001$), but this increase is reduced ($p = 0.03$-0.11) when measured on the aligned scans using the same mask. Conclusion: Opting for separate masks for dual-time analysis, the observed test-retest variability and dependence on segmentation method entails doubly biased measurements that can affect temporal comparability. Using the same mask on both scans after alignment of the scans introduces unreliable scan transformation-induced measurement changes. Thus, a better analysis technique to ensure comparability is needed.

PW050

The clinical application of absolute quantification SUV SPECT 99mTc-MIBI myocardial perfusion imaging to translate myocardial viability

W. He, W. Yu, W. Zhai, J. Xi; Huadong Hospital, Shanghai, CHINA.

Objectives: To investigate the relation of SUV values between 99mTc-MIBI and PET/CT in cardac imaging to evaluate myocardial viability. Materials and Methods: 32 consecutive patients with previous MI and left ventricular (LV) dysfunction (35±6%), mean±SD, who underwent 99mTc-MIBI SPECT and FDG PET/CT. Results of the two studies were divided into two types : myocardial perfusion match (group 1 MM) and myocardial perfusion mismatch (group 2 M). The SPECT/CT images were acquired using the standard clinical acquisition protocol (1800 scan arc, 64 frames in step-and-shoot mode, 25s per frame). The raw projection data was reconstructed using the software 'SUV-SPECT™'(HERMES MEDICAL SOLUTIONS). The reconstruction parameters were set to 16 subsets and 5 iterations. Corrections were applied for CT attenuation correction, Monte Carlo-modeled scatter correction, resolution recovery, scaling for injected dose and radioactive decay. The units of counts-per-voxel were scaled to activity per unit volume (Bq/cc) based on previously performed phantom calibration work to allow for SUV measurements and scaling of different myocardial segments and compare with FGD PET/CT SUV. Results : 23 patients were mismatch , while 9 match . The value of SUV 99mTc-MIBI myocardial perfusion was Inferior (4.1±0.3), septum (2.8±0.4), anterior (4.3±0.3) lateral (3.9±0.2),apex 2.3±0.1) , SUV in 30 Mismatch segments between SPECT/CT and PET/CT was no statistical difference , but SUV in 32 match segments was 20% to 55 %difference , which has signicant difference statistically. Conclusions : Absolute quantification SUV SPECT 99mTc-MIBI myocardial perfusion imaging can be a translator to evaluate myocardial viability , The multi center study planned to be built up to explore SUV cut off in 99mTc-MIBI myocardial perfusion imaging to evaluate viable myocardium.

Poster Walk 6 - Radiopharmacueticals & Radiochemistry: Radiopharmaceuticals II

PW051

One Pot Al18F Radiofluorination of GLU-UREA-LYS(AHX)-HBED-CC PSMA Ligand.

S. Boschi[1], F. Lodi[1], G. Cicoria[2], M. Marengo[2], S. Fanti[1]; [1]Nuclear Medicine, Bologna University Hospital, Bologna, ITALY, [2]Medical Physics, Bologna University Hospital, Bologna, ITALY.

Aim: Prostate cancer (PC) is the most commonly diagnosed cancer and the second leading cause of cancer death in men. Among PET radiopharmaceuticals 11C-choline and 18F-Fluorocholine have been proposed for the diagnosis, staging and restaging of PC although specificity and sensitivity of these tracers are not ideal. Recently 68Ga-labelled-PSMA ligands have been shown excellent results in detecting PC recurrence and metastases with high sensitivity and specificity. It is also well known that Fluorine-18 is the most popular and

attractive radionuclide for PET because of half-life and imaging characteristics; fluorinated tracers usually allow a higher patient throughput and the possibility of distribution of radiopharmaceutical to different users. Aim of this study was to label with Fluorine-18, via Al18F approach, the ligand Glu-Urea-Lys-(Ahx)-HBED-CC, which has been demonstrated to be of diagnostic value when labelled with Gallium-68. Results: Optimal condition for labelling Glu-Urea-Lys-(Ahx)-HBED-CC with Fluorine-18 using Al18F chemistry, in aqueous/ethanolic solution was investigated. The effect of ethanol concentration, reaction temperature, peptide amount on the labelling with Al18F as well as the effect of pH on the stability of the final product were studied. 100 μL (200-300 MBq) of 18F-fluoride in Acetate buffer 0.5M, 30 nanomoles of AlCl3 and increasing ethanol amount (30-180 μL) has been used. As demonstrated for other trivalent radiometals like 68Ga, the effect of increasing concentration of ethanol in the reaction mixture was to markedly increase the radiochemical yield (RCY). Increasing in RCY allowed a decrease in peptide concentration and in reaction temperature (30% of RCY with 90 μg of peptide at 100°C without ethanol compared to >90% labelling with 30μL of ethanol at 50°C). Increasing ethanol amount from 30μL to 180 μL in the reaction mixture led to >90% RCY at 50°C using 20 μg (21 nanomoles) of peptide. The labelled compound was further purified on SepPak C18 light cartridge, was stable for 3 hours in buffer pH 6.8 but not in saline. Two molecular forms (presumably diastereoisomers) were found, in agreement with Gallium-68 labelling data. Conclusion: These data demonstrates the feasibility of Al18F labelling of Glu-Urea-Lys-(Ahx)-HBED-CC. Radiofluorination of Glu-Urea-Lys-(Ahx)-HBED-CC was successfully obtained using the described method. The use of ethanol facilitates an efficient radiolabeling and could represent an important step toward the kit-type synthesis. Nevertheless, since automation of the synthesis is mandatory for radioprotection as well as for quality assurance issues, studies are in progress to transfer the synthesis on a fully automated cassette module.

PW052

We can do it without! Synthesis of F-18-labeled aromatic compounds without azeotropic drying, base and other additives

R. Richarz[1,2], P. Krapf[1,2], F. Zarrad[1,3], B. D. Zlatopolskiy[1,2], E. A. Urusova[1], B. Neumaier[1,3,2]; [1]Institute for Radiochemistry and Experimental Molecular Imaging, Cologne, GERMANY, [2]Max Planck Institute for Metabolic Research, Cologne, GERMANY, [3]Forschungszentrum Jülich INM-5 Short-lived radionuclides for life sciences, Jülich, GERMANY.

Aim: The classic ^{18}F labeling method via azeotropic drying of an aqueous [^{18}F]KF/cryptand system is time-consuming and error-prone. Furthermore, owing to highly basic raction conditions, base-sensitive precursors cannot be used. Published alternative labeling strategies of aromatic systems without azeotropic drying step are limitedly suitable for preparation of clinically relevant doses of PET-tracers. The aim of this work was to develop a novel radiolabeling approach using only onium precursors and [^{18}F]fluoride. Methodology: [^{18}F] fluoride is eluted from an anion exchange catridge with a solution of the appropriate onium precursor in different alcohols. After evaporation of the alcohol, a suitable solvent was added to the remaining onium (trimethylanilinium, diaryl iodonium or triarylsuilfonium, [^{18}F] fluoride) and the resulting solution was heated to provide the corresponding ^{18}F-labeled product. Results: Elution of $^{18}F^-$ with MeOH and EtOH solution of onium salt precursors proceeded almost quantitatively. Low-boiling MeOH colud be completely removed at 70 °C within 2-3 min. 2-, 3- and 4-[^{18}F]FBA were prepared in RCCs of 38-94% from the corresponding onium precursors. 28 GBq of 4-[^{18}F]FBA was prepared from 32 GBq [^{18}F] fluoride in high radiochemical purity (>98%) within 15 min. Different useful radiolabeling synthons, such as 4-[^{18}F]fluoroiodobenzene, the SFB analogue 2,3,5,6-tetrafluorophenyl 4-[^{18}F]fluorobenzoate as well as the model peptide 4-[^{18}F]fluorobenzoyl-βAla-Phe-OMe were produced from the corresponding sulfonium, anilinium and iodonium salt precursors in good RCCs in a single step. Conclusion: The minimalist ^{18}F labeling strategy is a completely new approach to the synthesis of various ^{18}F labeled compounds avoiding azeotropic drying as well as application of base and any other additives. The broad applicability of the novel procedure was demonstrated through the successful production of several useful radiolabeling synthons, as well as the one-step synthesis of a radiofluorinated model peptide. It was found, that MeOH and EtOH solutions yielded nearly quantitative [^{18}F] fluoride elution.

PW053

Microscale Radiolabelling of Antibodies with Zirconium-89 for Positron Emission Tomography

J. C. Knight[1], S. J. Paisey[2], C. Marshall[2], B. Cornelissen[1]; [1]University of Oxford, Oxford, UNITED KINGDOM, [2]Cardiff University, Cardiff, UNITED KINGDOM.

Aim: Over the last decade, several antibodies have been labelled with the radioisotope zirconium-89 (89Zr) for positron emission tomography (PET) studies. The radiochemical properties of zirconium-89 (particularly its radioactive half-life [t1/2 = 3.2 days]) make it well-suited to antibody imaging and 89Zr-labelled antibodies have been used successfully in clinical settings as tools for early detection and characterisation of certain cancers,

and as companion diagnostics during therapy. The most widely cited method for desferrioxamine (DFO)-conjugation and radiolabelling of antibodies with 89Zr requires multi-milligram (2-10 mg) quantities of protein in order to achieve adequate radiolabelling yields (>85%). During the research and development process, obtaining antibodies in such quantities can be cost-prohibitive when the antibody has to be sourced from a commercial supplier. This can also be a hindrance when the availability of the antibody in question is limited. To circumvent this limitation in the current method and aid in the preclinical evaluation of 89Zr-labelled antibodies, we sought to develop an 89Zr-radiolabelling procedure that would provide high radiochemical yields at the microscale. Materials and Methods: Tocilizumab (RoActemra®) (200-500 μg) was modified with a 10-fold molar excess of p-SCN-Bn-DFO and prepared at a concentration of 2 mg/mL in phosphate buffered saline (pH 7.4). Zirconium-89 in 1 M oxalic acid was adjusted to pH 7-8 by the addition of 1 M sodium carbonate and the resulting solution was added to the DFO-Tocilizumab solution to achieve a ratio of 0.1 MBq to 1 microgram of antibody. The reaction mixtures were incubated at room temperature for 1 h and the radiochemical yield was determined by iTLC using an eluent of 50 mM DTPA (pH 7). The reaction was performed using decreasing amounts of antibody in the range 100 to 10 μg. Results: Radiochemical yields of 96±4%, 80 ±11%, 68±27%, 71±16%, and 63±18% were obtained using 100, 75, 50, 25, and 10 μg of DFO-Tocilizumab, respectively. Conclusions: The reported method results in excellent radiochemical yields using 100 μg of DFO-antibody which compares very favourably with other methods in the literature. Using even smaller amounts of antibody provided lower, albeit still adequate radiochemical yields for preclinical research applications. Furthermore, this approach does not require access to specialised equipment and can be readily implemented in research facilities with minimal radiochemistry infrastructure. Research support: This work received financial support from Cancer Research UK.

PW054

Direct production of 99mTc with a cyclotron

M. Aboudzadeh Rovais; Nuclear Science and Technology Research Institute, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Introduction: Technetium-99m (99mTc) is commonly obtained from 99Mo/99mTc generators. Recent shortages of 99Mo have led to an examination of alternative production methods that could contribute to a more robust supply. A cyclotron has been used to produce 99mTc. Production conditions such as beam and target characteristics and purification need to be optimized in order to maximize the amount of 99mTc and minimize impurities. The focus of this manuscript is on the cyclotron production of 99mTc. Method: The cross section calculations and proton project rangewere performed using the computer codes Talys-1.6 and SRIM, respectively. 99mTc was produced with newly designed and manufactured shuttle and canister target system. Essential target thickness and production yield were calculated. The 100Mo target was irradiated with 19 MeV protons for 1h at up to 50 μA. Solvent extraction method using MEK/NaOH system followed by an acidic alumina column chromatography was employed for the radiochemical separation and purifications. Results and discussion: A simple and quick procedure has been proposed and assessed for the 99mTc production with a cyclotron. Thick target calculations suggested that a large quantity of cyclotron-produced 99mTc via 100Mo(p,2n) reaction is possible. Integration of the excitation function for protons degraded from 19→9 MeV using 100% isotopic enriched 100Mo suggests the maximum production yield of 377 MBq•μA-1•h-1. The average production yield was measured to be 356 MBq•μA-1•h-1. In comparison, the practical yield obtained in this work is very close to the calculated yield. The 99mTc obtained by the combined solvent extraction and alumina column chromatography had good quality in terms of radionuclidic, radiochemical and chemical purity. It has been shown that the QC parameters were within the USP specifications. Keywords: Cyclotron • 99mTc production • targetry • simulation.

PW055

Determination of nickel in ^{64}Cu-ATSM preparations: development and validation of a colorimetric method as impurity limit test

S. Costa, C. De Nicolo, G. Cicoria, C. Malizia, S. Fanti, F. Lodi; S.Orsola-Malpighi University Hospital, Bologna, ITALY.

Aim. ^{64}CuATSM is a radio-pharmaceutical used for revealing hypoxic areas and predict treatment efficacy. ^{64}Cu is produced by (p,n) reaction on metallic ^{64}Ni. The synthesis is performed by means of a complete automatic module that allow to purify the ^{64}Cu from enriched ^{64}Ni. Due to the high amount of the target material (120 mg), traces of nickel could be found in the final formulation. Quality parameters defined in European Pharmacopoeia include Nickel maximum concentration that should not exceed 25 μg in the maximum injectable volume.

A fast colorimetric method was developed and validated as impurity limit assay. Materials and Methods. In this method a sample containing an unknown amount of nickel, and a reference standard containing 5 μg/ mL of nickel are diluted 1:20. After that they are both treated with a solution containing I^-/I_2 in order to oxidize Ni^{n+} to Ni^{4+} and then pH is bring up to 10 - 12 with a NH_3 watering solution. A dimethylglyoxime solution is added and Ni^{4+} forms a red-brown soluble complex with dimethylglyoxime (stoichiometry 1:1). The standard and the sample solutions are then compared. A commercial colorimetric kit for nickel quantification in water substrates was used as starting point; the reference method was the inductively coupled plasma mass spectrometry (ICP-MS). Specificity and limit of detection were determined according to the ICH Q2 guidelines: interferences of the whole matrix (ethanol 10%v/v, NaCl 0.9% w/v in ultra pure water) and the matrix single components at different concentrations were evaluated; interference of copper ions at different concentrations was also investigated. The lower detectable concentration was experimentally determined. Results. Matrix does not interfere with the test, while copper does at concentration higher than 0.75 mg/L. The assay limit of detection in our experimental conditions was 0.04 mg/L. The nickel limit test was then successfully applied to four different ^{64}Cu-ATSM batches. The results were in accordance with those found with ICP-MS. Conclusions. The colorimetric nickel limit test is faster and cheaper than other methods (i.e. ICP-MS) and can be well applied to the Quality Control determination of Ni in ^{64}CuATSM preparations.

PW056

Synthesis of 68Ga Radiopharmaceuticals for Cell Radiolabelling Using Anion Exchange Column

A. Socan[1], P. Kolenc Peitl[1], M. Kroselj[1], C. Rangger[2], C. Decristoforo[2]; [1]University Medical Centre Ljubljana, Ljubljana, SLOVENIA, [2]University Clinic for Nuclear Medicine, University for Medicine, Innsbruck, AUSTRIA.

AIM: 68Ga labelled radiopharmaceuticals are gaining increasing importance in the field of PET nuclear medicine imaging, due to availability of several synthesis modules and 68Ge/68Ga generators on the market enabling users to produce radiopharmaceuticals according to current pharmaceutical standards. Studies showed that although the half life of 68Ga is a limiting factor, 68Ga radiolabelled cells could be used in certain clinical indications. The aim of our study was to develop a novel, versatile approach to prepare 68Ga radiopharmaceuticals (oxine, tropolone) for cell labelling using concentration of 68Ga on an anion exchange column (SepPAK QME). MATERIALS: Column was washed with 2 ml of water. Samples of 68Ga-acetate (Na-acetate, 155mg/ml), -HEPES (1M HEPES) and -citrate (0,1M Na-citrate, pH 5) solutions, samples varying in pH (4-7) and volume, were prepared and applied on column. Activity retained on, activity washed from column and pH of solution was measured. Sample of 0,3 ml ligand solution (tropolone:1mg/ml, water; oxine:1mg/ml, 20% ethanol) was applied on column and incubated for 10 minutes. Column content was washed from column with 2 ml of PBS. Activity and pH measurements were performed as described above. 68Ga-complex formations were analyzed using extraction method into octanol. RESULTS: Yield of activity retained on column with 68Ga-citrate varied 17-96% and was pH and volume dependent. Yield decreased with volumes applied greater than 2 ml and pH bellow 4,5. Yield of 68Ga-tropolone solution was above 75% with pH between 4,4-5 and extraction into octanol above 89%. Yield of 68Ga-oxine solution was between 27-83% with pH between 5, 2-6,7 and extraction into octanol above 94%. With 68Ga-acetate yield of activity retained on column was above 95% and was not pH (3,8-5,9) and volume dependent (0,5-6ml). Yield of 68Ga-tropolone solution was above 81% with pH between 5,4-6,8 and extraction into octanol abobe 90%. Yield of 68Ga-oxine solution was between 40-65% with pH between 4,8-6,3 and extraction into octanol above 92.2%. 68Ga-HEPES yield of activity retained on column was above 89% and was not pH (3,7-7,3) and volume dependent (0,5-2, 5ml). Yield of 68Ga-oxine solution was between 43-77% with pH between 6,1-7,4 and extraction into octanol above 96%. CONCLUSIONS: Concentration of 68Ga in various buffer systems on an anion exchange column allows on-column formation of lipophilic complexes (oxine, tropolone) in very small volumes suitable for cell labelling with high yields and quality. This is a versatile and promising tool to prepare 68Ga-precursors for cell labelling potentially suitable for automated systems.

PW057

A real-time in vitro assay as a potential predictor of in vivo tumour imaging properties

D. Spiegelberg[1], **J. Stenberg**[1], A. Haylock[2], M. Nestor[1,2]; [1]Department of Immunology, Genetics & Pathology, Uppsala, SWEDEN, [2]Unit of Otolaryngology and Head & Neck Surgery, Department of Surgical Sciences, Uppsala, SWEDEN.

Aim: Predicting *in vivo* tumour binding properties of molecular imaging agents with reliable *in vitro* assays is a useful approach to increase preclinical knowledge and limit the use of laboratory animals. To our knowledge, no *in vitro* analysis methods have yet been established to accurately estimate the performance of radiolabelled binders in tumour xenografts. AbD15179 is a promising antibody fragment for molecular

imaging of CD44v6, a non-internalising antigen overexpressed in head- and neck carcinomas. In this study, we investigated if real-time *in vitro* kinetics of AbD15179 receptor binding on CD44v6-expressing tumour cells could be used to predict aspects of the *in vivo* tumour imaging properties. Materials and Methods: Antibody fragment (Fab) Abd15179 was either labelled with ^{125}I using Chloramine T or with ^{111}In using CHX-A"-DTPA. Interactions of labelled fragments with receptors *in vitro* were measured over time on high- (A431) and intermediate (H314) CD44v6 expressing tumour cells with LigandTracer. Using a dual isotope approach, the same batch of ^{111}In- or ^{125}I labelled Fab conjugates were injected in twenty mice bearing both A431 and H314 tumour xenografts. Tumour uptake as well as sensitivity and specificity of conjugates could then be measured while eliminating inter-subject variability. Simultaneous characterisation of the same conjugates *in vitro* and *in vivo* reduced potential bias from batch variability and specific activity. Results: Binding of radiolabelled AbD15179 to cells *in vitro* mainly consisted of two interactions: one high-affinity binding event with slower dissociation and one low-affinity binding event with faster dissociation. The proportion of high-affinity binders was considerably higher for ^{111}In-Fab than for ^{125}I-Fab, leading to a slower release of ^{111}In-Fab than ^{125}I-Fab from tumour cells. Clear differences in signal intensity for ^{111}In-Fab binding were present between CD44v6 high- (A431) and moderate (H314) expressing cells. In contrast, no differences between the two cell lines could be seen for ^{125}I-Fab. In accordance with *in vitro* results, ^{111}In-labeled fragments dissociated slower from tumours compared to ^{125}I-Fab and also made it possible to distinguish between A431 and H314 xenografts *in vivo*. Conclusion: Interaction properties *in vitro* correlated strongly with *in vivo* conjugate binding for CD44v6-targeting Fabs. Thus, time-resolved experiments on living cells could in this case adequately predict the performance of radiolabelled binders on mouse xenografts. If proven general, this finding may lead to a reduction of laboratory animal use in future development of tumor targeting compounds.

PW058

44Sc- and 177Lu-labeling of DKFZ-617 for dosimetry and therapy of prostate cancer

E. Eppard[1], A. de la Fuente[2], S. Kuerpig[1], F. Roesch[2], M. Essler[1]; [1]University Hospital Bonn, Bonn, GERMANY, [2]Johannes Gutenberg-University, Mainz, GERMANY.

OBJECTIVES: Radiolabeling of the prostate-specific membrane antigen (PSMA) inhibitor, Glu-NH-CO-NH-Lys (Ahx), using DOTA as chelator, a broad pool of radionuclides becomes available for labeling. These possible variations allow the visualization of the biological behavior over different periods of time depending on the half-life of the used radionuclide (68Ga t1/2 = 68 min; 44Sc t1/2= 3.9 h). Additionally, the usage of different imaging modalities or endoradiotherapies can be applied depending on the employed radionuclide. METHODS: DKFZ-PSMA-617 was obtained from ABX (Radeberg, Germany). 44Sc was obtained from a 44Ti/44Sc generator in Mainz, where 44Ti decays with a half-life of 60 d to no-carrier-added (n.c.a) 44Sc. Radiolabeling with 44Sc was performed in 3 mL 0.25 M ammonium acetate buffer with varying amount of ligand at 95°C. 177Lu was obtained from IDB Holland and labeling was performed in a gentisinic acid/sodium ascorbate solution with varying amount of ligand at 95°C. Purification (if needed) was performed using C-18 cartridges for both compounds. Quality control was performed using radioHPLC and radioTLC. Stability studies were performed at 37°C in different media (human serum, NaCl) over one half-live. RESULTS: 44Sc-DKFZ-PSMA-617 and 177Lu-DKFZ-PSMA-617 were effectively labeled at 95 °C. Subsequent cartridge-based solid-phase-extraction (C-18) resulting in a radiochemical purity of the final tracers of ≥98% can be applied for both compounds. Stability studies in different media (human serum, NaCl etc.) were successfully performed and both compounds showed high stability over a period of one half-live or longer. Radiochemical purity could be analyzed effectively using radioHPLC and radioTLC. 177Lu-DKFZ-PSMA-617 is utilized using the optimized labeling protocol for patient treatment since November 2014. CONCLUSIONS: The radiolabeling of DKFZ-PSMA-617 with the new generator-derived PET radionuclide 44Sc was investigated in detail. 44Sc-DOTA-PSMA was investigated in vitro. Further investigations including cell studies, biodistribution and small animal μPET are planned. Also radiolabeling of 177Lu-DKFZ-PSMA-617 was optimized with regard to therapeutic application and successfully integrated in clinical routine.

Development of [18F]Fluoro-sugar based prosthetic groups for the PET imaging of radiolabel peptides

C. Collet[1,2], F. Maskali[1], S. Poussier[1,2], A. Mohamadi[3,2], V. Regnault[3,2], P. Lacolley[3,2], Y. Chapleur[1,2,4], P. Marie[1,2,3], G. Karcher[1,2], S. Lamandé-Langle[4,2]; [1]Nancyclotep, Vandoeuvre les Nancy, FRANCE, [2]Université de Lorraine, Vandoeuvre les Nancy, FRANCE, [3]Inserm UMR 1116, Vandoeuvre les Nancy, FRANCE, [4]UMR 7565, Vandoeuvre les Nancy, FRANCE.

Introduction: The direct ^{18}F-labelling of biomolecules, such as proteins, peptides or oligonucleotides, is not possible under harsh conditions, but it may be obtained through a prosthetic group, a small molecule that may be labelled, with ^{18}F and

subsequently coupled in mild condition to the biomolecule. We aimed to develop sugar based prosthetic groups in this setting, a method that is likely to improve the bioavailability, pharmacokinetic and *in vivo* clearance properties of peptide/protein.Materials & Methods: The prosthetic carbohydrate derivatives should have a good leaving group allowing an easy substitution by fluorine-18. A Huisgen cycloaddition was planned for coupling the prosthetic group with the biomolecule. Some peptides containing a cysteine residue were initially tested. *S*-propargylated derivatives were easily obtained thanks to the high nucleophilicity of the thiol function. The fully automated radiosynthesis of these [^{18}F]fluoroglycopeptides was performed on an AllInOne (Trasis®) module. In the same time the biological activity of these glycopeptides was evaluated *in vitro* (platelet aggregation assay). IC_{50} values were determined from concentration-response curves fitted with an exponential decay equation. PET scans will be performed using a small-animal INVEON tomograph.Results: The synthesis of suitable precursors of these prosthetic groups and the radiolabelling of some model peptides (glutathione, RGDC, c(RGDfC)) could be successfully achieved by a two step strategy for the radiolabelling of peptides using sugar based prosthetic group[^{18}F]Fluoroglycopeptides were obtained in 10-30% radiochemical yield (dc). PET-scan images were obtained in animals. *In vitro* studies of ADP-induced platelet aggregation inhibition show that introduction of a carbohydrate moiety on linear RGD peptides strongly enhances the inhibitory activity.Discussion/Conclusion: The ^{18}F-labelling of peptides is possible in good yields by using prosthetic groups constituted of 6-fluoro sugars, equipped with an azido arm at the anomeric position. Biological evaluations are very promising.

PW060

Cyclotron production of 51Cr for clinical application

M. Aboudzadeh Rovais; Nuclear Science and Technology Research Institute, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Introduction: ^{51}Cr(27.7d) is one of the attractive medical radionuclide that decays via electron capture (EC=100%). The ^{51}Cr is used to label red blood cells and quantify gastrointestinal protein loss. Sodium chromate ($Na_2{}^{51}CrO_4$) and chromium chloride ($^{51}CrCl_3$) are suitable for diagnostic applications. In this article, a selection of different reactions for production of ^{51}Cr, theoretical production yield through the excitation functions for ^{51}V(p,n)^{51}Cr, ^{51}V(d,2n)^{51}Cr, ^{48}Ti(α,n)^{51}Cr, ^{52}Cr(n,2n)^{51}Cr using TALYS 1.6, ALICE-91 and ALICE-ASH computer codes have been studied. The experimental yield as well as the production method for ^{51}V(p,n)^{51}Cr reaction are presented. Also, the essential target thickness was calculated by SRIM computer code. Method: The production of ^{51}Cr following direct ^{51}V(p,n)^{51}Cr reaction, 250mg V_2O_5(99.99% Merck) were compressed into pellets. A novel shuttle and target system was developed for the production of ^{51}Cr. The incident energy of the proton beam was 11MeV at the 20μA current for 1hr. The irradiated target was dissolved in 4N HCl(2ml) containing 10mg of ferric nitrate. The solution was added slowly to the boiling 4N NaOH(2ml). ^{51}Cr was precipitated with Fe^{3+} as a co-precipitation. The precipitate was separated from the solution by filtration and then it was dissolved in 12N HCl(10ml). The solution was passed through a chromatography column that filled with Dowex 1X8 anion exchange resin (mesh 100-200). Fe^{3+} was retained by the resin while the Cr^{3+} was passed through. Results and discussion: Different products and theoretical production yield of ^{51}Cr in different nuclear reaction were studied through the excitation functions using the previously mentioned computer codes. Although the direct ^{51}V(p,n)^{51}Cr reaction doesn't have the best ^{51}Cr production yield, this reaction is the only one that can produce no career-added ^{51}Cr and pure as the final product. The average of the experimental yields of ^{51}Cr over the optimum energy range E_p=11→3 MeV for ^{51}V(p,n)^{51}Cr reaction was 2.3MBq/μAh. The theoretical yield of ^{51}Cr was calculated as 2.7, 2.9 and 2.5 MBq/μAh for TALYS, ALICE-91 and ALICE-ASH codes, respectively. Conclusion: The ^{51}V(p,n)^{51}Cr reaction was selected because of the ^{51}Cr could be produced free of the other radionuclides. A novel targetry system was developed for this production method. The experimental production yields are close to the theoretical yields especially the one calculated from the ALICE-ASH code. Keywords: ^{51}Cr, Production yield, Pellet target, Simulation.

Brown adipose tissue: Preclinical imaging beyond FDG?

M. Bauwens[1], G. Hendrikx[1], V. Schrauwen-Hinderling[1], J. Slenter[1], S. van Hoof[1], A. Vogg[2], I. Pooters[1], B. Brans[1], F. M. Mottaghy[1,2]; [1]MUMC, Maastricht, NETHERLANDS, [2]UKAachen, Aachen, GERMANY.

Introduction: The metabolic activity of brown adipose tissue (BAT) can have a significant effect on homeostasis, but is difficult to non-invasively quantify in vivo. In this study, we

performed a comparison of different non-invasive imaging techniques in a preclinical setting. Methods: 40 Wistar rats (male, 8-12 weeks old) and 42 NMRI mice (male, 6-9 weeks old) were used during the study. In rats, dynamic PET and SPECT images using [18F]-FDG, [18F]-FTHA, [123I]-MIBG, [99mTc]-MIBI and [123I]-IPA were acquired in different temperature conditions: room temperature, exposure to acute cold (4°C for 4h) or acclimatized to cold (4°C for 6h per day during 28 days). MRI/MRS was set up using a dedicated protocol to assess BAT temperature in 5 room temperature and cooled rats. In NMRI mice, static PET images were acquired using [18F]-FDG and [18F]-FTHA and using different temperature conditions (room temperature, thermoneutral conditions and 4°C) as well as a different diet (chow or high-fat diet). In addition, CT images were acquired in these mice and used as a cross-reference for the PET images. Finally, mRNA of several genes was analyzed from BAT and WAT. Results: In rats, [18F]-FDG, [18F]-FTHA, [123I]-MIBG, [99mTc]-MIBI but not [123I]-IPA allowed to visualize BAT and showed higher uptake in cold-stimulated animals. When compared to a single cold-exposure, the effect of cold-acclimatization yielded a larger volume of active BAT, indicating growth of BAT. MRI clearly showed BAT in T2 weighed images. MRS could quantify BAT temperature, but did not reveal a temperature difference between BAT and a reference region. In mice, [18F]-FDG and [18F]-FTHA could visualize BAT. However, only [18F]-FDG showed clear images and allowed a comparison between different groups, and showed the impact of the high-fat diet (lower uptake compared to chow) as well as temperature conditions (cold-stimulated animals showed more uptake). CT images clearly showed BAT, improving BAT delineation on PET images, but yielded no further additional information. mRNA confirmed the identity of BAT in all animals, and showed a clear correlation between mRNA expression and related tracer uptake. Summary: PET, SPECT, CT and MRI/MRS are all able to visualize interscapular BAT. The lack of good quantitative information from the SPECT makes it a currently suboptimal technique . In our current study, [18F]-FDG outperforms any other tracer. The combination of PET/CT and PET/MRI is nevertheless superior to only PET, due to better target delineation.

PW062

Pilot study of a novel peptide targeting GPC3 for HCC

D. Zhu[1], Y. Qin[1], L. Zhang[2], S. Zou[1], J. Wang[2], L. Zhu[2], **X. Zhu**[1]; [1]Department of Nuclear Medicine & PET, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA, [2]State Key Laboratory of Molecular Vaccinology and Molecular Diagnostics & Center for Molecular Imaging and Translational Medicine, School of Public Health, Xiamen University, Xiamen, CHINA.

Purpose: Glypican-3 (GPC3) is a heparan-sulfate proteoglycan over-expressed in most hepatocellular carcinoma (HCC). A peptide binds to GPC3 with high specificity and affinity will facilitate targeted diagnosis and/or therapy of HCC.Methods: A Ph.D.-12TM phage display library was used to screen the high affinity peptide against the human recombinant GPC3 protein. A 12-mer peptide GPC3-TJ12P1 was synthesized according to the DNA sequence of selected GPC3 binding phage. The binding affinity between GPC3-TJ12P1 and the human recombinant GPC3 protein was determined by ELISA. Specificity of GPC3-TJ12P1 to GPC3 was confirmed by western blot and cell florescent on cells with (HepG2) or without (PC3) GPC3 expression. In vivo, near-infrared fluorescent (NIRF) imaging and biodistribution studies were performed in nude mice bearing HepG2 and PC3 tumor xenografts to evaluate the target ability of Cy5.5-GPC3-TJ12P1 to GPC3. Furthermore, Cy5.5- GPC3-TJ12P1 was used to detect the GPC3 expression in patient's tumor tissues with HCC, cholangiocarcinoma (CCA) and normal adult liver tissues respectively using western blot and immunohistochemical staining.Results: The binding assay of the GPC3-TJ12P1 to GPC3 protein exhibited Kd value of 280.4 ± 33.51nM. Western blotting confirmed that GPC3-TJ12P1 was able to effectively detect GPC3 expression in HepG2 and PC3 cells. Cy5.5-GPC3-TJ12P1 mainly attached to HepG2 cells surface under confocal microscopy, while there were less fluorescent on the PC3 cells membrane. A weak signal was observed when GPC3 expressed on HepG2 cells were blocked by free GPC3-TJ12P1 before Cy5.5-GPC3-TJ12P1 labeling. In vivo NIRF study showed that HepG2 xenograft tumors had a higher accumulation of Cy5.5-GPC3-TJ12P1 than that of control group, blocking group and PC3 xenograft tumors (n=3 or 4), respectively. Tumor/muscle fluorescent intensity ratio reached 3.98 ± 0.36 at 4h post-injection in HepG2 tumor models. Ex vivo study also confirmed that an enrichment of Cy5.5-GPC3-TJ12P1 at 4h in the HepG2 dissected tumors. For patient's tissues, only GPC3 protein strip from HCC tissues was displayed with fluorescent on PVDF membrane, and there was a heavier staining in HCC slices than that of in CCA and normal adult liver slices, which confirmed using anti-GPC3 mAb simultaneously.Conclusions: A novel peptide, GPC3-TJ12P1, targeting GPC3 was obtained using phage display library and identified in vitro and in vivo. It can be applied for further studies, such as peptide mediated multifunctional molecular imaging and drug deliveries as well as a new promising molecular probe for early HCC diagnosis and intervention.[Keywords]phage display library; Peptide; GPC3; HCC; Optical imaging

PW063

A new lactam bridge 99mTc-α -melanocyte-stimulating hormone analog for diagnosis of metastatic melanoma

D. Beiki[1], D. Shamshirian[2], M. Erfani[3], B. Fallahi[1]; [1]Research Center for Nuclear Medicine, Shariati Hospital, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Department of Radiopharmacy, School of Pharmacy, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]Radiation Application Research School, Nuclear Science and Technology Research Institute, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Introduction: Over 80 % of human metastatic melanomas were reported to overexpress MC1 receptors. Since melanoma cause more than 75% of deaths from skin cancer, there is a need to develop new radiopharmaceuticals which allow diagnosing this type of tumor in an early phase. This study presents the synthesis of a new lactam bridge 99mTc-α-MSH analogue. Methods: A new [HYNIC-GABA-Nle]-CycMSHhept derivative was conveniently synthesized by solid phase peptide synthesis on sieber amide resin via Fmoc strategy. Then peptide radiolabelling was performed by 99mTc via HYNIC chelator and tricine as co-ligand. Also, stability in human serum, receptor bound internalization, protein binding, partition coefficient and tissue biodistribution in tumor bearing nude mice were thoroughly investigated. Results: The new peptide derivative was obtained in an overall yield of 35% with the purity of >98%. Radiolabeling with 99mTc was performed at high specific activities (163MBq/nmol) with an acceptable labeling yield (>98%). Also, stability studies in aqueous solution and human serum showed radiolabeled complex with no significant release of 99mTcO4− or peptide degradation up to 6 h. Protein binding and calculated partition coefficient for the radiolabeled peptide were 37% and log P=−1.31 ± 0.12 %, respectively. Also, the radioligand showed specific internalization into B16/F10 cells (13.35 ± 0.9% at 4 hours). In biodistribution studies, a receptor-specific uptake was observed in MC1 receptor positive organ so that after 4 hours the tumor uptake was 4.51±0.11 % ID/g. Predominant renal excretion pathway with a highest accumulation of activity in tumor was observed for this radiopeptide. Conclusion: This new designed labeled peptide conjugate showed high accumulation in tumor as a positive MC1 receptor targeted tissue followed by excretion via the kidney and can be a suitable candidate for diagnosis of metastatic melanomas.

PW064

Multispectral fluorescence imaging during robot-assisted laparoscopic sentinel node biopsy - a first step towards a real-time intraoperative patient-specific anatomical roadmap

N. S. van den Berg[1,2], G. H. KleinJan[1,2], T. Buckle[1], E. M. Wit[2], H. G. van der Poel[2], F. W. B. van Leeuwen[1,2]; [1]LUMC, Leiden, NETHERLANDS, [2]AVL-NKI, Amsterdam, NETHERLANDS.

Introduction:The clinical translation of hybrid tracers, e.g. the sentinel node (SN) tracer indocyanine green (ICG)-99mTc-nanocolloid, that are composed of a radioactive- and optical signal has strongly expanded the working-field of nuclear medicine by providing real-time fluorescence guidance during surgery. Limiting, however, is that surgical guidance remains restricted to a single feature such as the SN. If real-time surgical guidance can be provided for multiple parameters at once, it may help create a paradigm shift in the way surgery is performed. For this multispectral imaging concept multiple (spectrally complementary) fluorescent tracers have to be administered to a single patient. Also a fluorescence camera is required that allows for separate detection of the two signals. Following an initial evaluation in mice, in the current study we clinically evaluated this approach using ICG-99mTc-nanocolloid (SN; near-infrared (NIR)) and fluorescein (lymphangiography; visible fluorescence).Methods:For the first-in-human application, 8 prostate cancer patients with a Briganti nomogram-based risk >10% of lymph node metastases were included. Patients were scheduled for robot-assisted radical prostatectomy with extended pelvic lymph node dissection and SN biopsy. Following a transrectal ultrasound-guided intraprostatic ICG-99mTc-nanocolloid injection (2.0mL; 3h prior to surgery) preoperative lymphoscintigraphy and SPECT-CT imaging were performed. Fluorescein (2.0mL; 200mg) was injected into the prostate directly after anesthetizing the patient. Intraoperatively both fluorescent signatures were identified using a tailored multispectral fluorescence laparoscope.Results:Preoperative SPECT-CT imaging revealed on average 3.9 SNs (range 1-6) per patient. Intraoperatively, 24 of 28 SNs (85.7%) could be detected using the NIR settings. In 5 patients, the fluorescence signal of fluorescein could be used to specifically highlight the draining lymphatic ducts to 10 SNs.The accuracy and brightness with which fluorescein could be detected in vivo was remarkable. However, compared to the hybrid tracer, with fluorescein a higher background staining was seen (predominantly bowel, urine). Also this study underlined that the

guidance provided by a dedicated SN tracer is superior over the guidance provided by a lymphangiography tracer.Discussion:This study illustrated the first-in-human use of a multispectral fluorescence guidance approach using two complementary fluorescent tracers. The promising results provide a first step towards a fluorescence-based anatomical/molecular road map able to visualize multiple surgery-related anatomical structures simultaneous.

PW065

Effect of different injection routes in tumor accumulation and biodistribution of radiolabeled Pluronic P94 unimers

C. Santini[1], A. Arranja[2], A. Denkova[3], F. Schosseler[2], K. Morawska[4], P. Dubruel[4], E. Mendes[5], M. de Jong[1], M. Bernsen[1]; [1]Erasmus MC, Rotterdam, NETHERLANDS, [2]CNRS, Institute Charles Sadron, Strasbourg, FRANCE, [3]TU Delft, Radiation Science and Technology,, Delft, NETHERLANDS, [4]UGhent, Polymer Chemistry and Biomaterials Group (PBM), Gent, BELGIUM, [5]TU Delft, Department of Chemical Engineering, Delft, NETHERLANDS.

Introduction. Pluronic P94 unimers (P94) are amphiphilic block copolymers with high in vivo stability and relatively long circulation times. Due to the enhanced permeability and retention (EPR) effect, P94 can accumulate in the tumor tissue and therefore be potentially used as drug carrier. For various macromolecules it has been shown that following IV administration, limited tumor accumulation occurs versus undesired high liver uptake and clearance via the mononuclear phagocyte system (MPS). Intratumoral (IT) injection might overcome this limitation by avoiding the systemic circulation and therefore improving the retention in the tumor. In this study we compared IT versus IV administration routes of radiolabeled P94 in terms of biodistribution profiles and tumor accumulation and retention in a mouse tumor model.Materials and methods. P94 was modified with a DTPA chelator, labeled with 1In-111 and injected in tumor-bearing mice either IV (N=8, 0.2 mg/mouse, ~10 MBq/animal) or IT (N=8, 0.1 mg/mouse, ~5 MBq/animal). Molecular imaging with SPECT/CT was performed at different time points post injection (pi): 30 min, 24h, 48h and 96h pi. Ex vivo biodistribution was determined in isolated organs at 48h and 96h pi.Results. Following IV injection, accumulation in the liver was visible already 30 min pi, while tumor accumulation could be visible only starting from later time points. Ex vivo biodistribution, confirmed a reduced tumor uptake of ~1 % injected dose per gram (ID/g), whereas accumulation in the liver was ~15 %ID/g. In contrast, following IT injection most of the signal is concentrated in the tumor rim and limited liver accumulation is detected in the first hour pi. Furthermore, ex vivo biodistribution following IT injection, showed that the tumor retention increased to over 20 %ID/g, with limited uptake in off-target tissues, while liver uptake was reduced to ~10 %ID/g. The results also indicated that, independently from the injection route, the tumor could retain P94 over time, while the majority of other tissues show a significant reduction in tracer retention between 48h and 96h. The effect is however larger after IT injection.Conclusion. IV injection of radiolabeled P94 resulted in limited tumor uptake, whereas IT administration substantially increased the uptake and the retention in the tumor. The minimal involvement of off-target tissue, including liver, and the tracer retention over time especially for IT administration, confirmed the potential of P94 to be used as a carrier for therapeutic radionuclides.

PW066

A multiprobe approach to monitoring therapy response in rheumatoid arthritis

S. Y. A. Terry[1], M. I. Koenders[2], T. K. Nayak[3], A. Freimoser-Grundschober[4], C. Klein[4], W. J. Oyen[2], O. C. Boerman[2], P. Laverman[2]; [1]King's College London, London, UNITED KINGDOM, [2]Radboud UMC, Nijmegen, NETHERLANDS, [3]Roche Pharmaceutical Research and Early Development, Basel, SWITZERLAND, [4]Roche Pharmaceutical Research and Early Development, Zurich, SWITZERLAND.

Introduction: Rheumatoid arthritis (RA) is an autoimmune disease leading to chronic synovial inflammation. Monitoring therapy response by molecular imaging may allow optimization of therapy regimens and/or improve therapeutic outcome. Etanercept is a soluble fusion protein consisting of human p75 TNF-α and the Fc portion of human IgG and is often given to RA patients if methotrexate is contra-indicated or withdrawn due to adverse events. Here, we focused on imaging three different targets that play a role in arthritis, namely fibroblast activation protein (FAP), macrophages, and integrin $\alpha_v\beta_3$, and on determining whether specific imaging of these targets could monitor response to etanercept in RA mice. Methods: Male DBA/1J mice with collagen-induced arthritis were treated with anti-TNFα therapy (etanercept 10 mg/kg, 3x/week, i.p.). SPECT/CT scans were acquired of treated and untreated mice

at 1, 24 and 48 hours after injection of ^{111}In-RGD$_2$ peptide (targeting integrin $\alpha_v\beta_3$; 1 μg/mouse), ^{111}In-anti-F4/80 antibody (targeting macrophages; 10 μg/mouse), or ^{111}In-28H1 antibody (anti-FAP; 50 μg/mouse), respectively. Mice were dissected after the last scan to determine the biodistribution. Coinjection of an excess of RGD$_2$ with ^{111}In-RGD$_2$ or injection of ^{111}In-labeled control antibodies (rat IgG2b or DP47GS) served as controls to determine nonspecific tracer uptake. Results: RA was imaged with ^{111}In-28H1, ^{111}In-anti-F4/80, and ^{111}In-RGD$_2$. Treatment with etanercept was successful as macroscopic scores of RA were lower in treated mice than in untreated mice (Figure 2). At day 6 after start of therapy, average RA scores were 3.99 ± 1.67 in untreated mice and 1.84 ± 1.08 in treated mice. Tracer uptake in joints correlated with RA score in biodistribution studies and quantitative SPECT; uptake decreased from 28±15%ID/g, 8±4%ID/g, 2±1%ID/g to 11±11%ID/g, 4±4%ID/g, 1±0%ID/g in treated and untreated mice for ^{111}In-28H1, ^{111}In-anti-F4/80, and ^{111}In-RGD$_2$, respectively ($p<0.001$). Joint uptake of ^{111}In-28H1, ^{111}In-anti-F4/80, and ^{111}In-RGD$_2$ is antigen/receptor-mediated as when competing uptake of these tracers with either antibody controls or excess of peptide, joint:blood values decreased. RA-to-blood ratios (in mice with arthritis score 2) were higher for ^{111}In-28H1 (6±1, lowest population), ^{111}In-anti-F4/80 (10 ±4), and ^{111}In-RGD$_2$ (7±1) than for control ^{111}In-DP47GS (1 ±1), ^{111}In-rat IgG2b (1±0), or coinjection of excess RGD$_2$, (4 ±0). Conclusions: The three tracers can be used to specifically monitor the response to therapy in RA at the molecular level.

PW067

The imaging study of a new 99mTc-labeled PSMA inhibitor

X. Xu; J. Zhang, S. He, J. Luo, Y. Zhang *Department of Nuclear Medicine, Fudan University Shanghai Cancer Center, Shanghai, ChinaDepartment of Oncology, Shanghai Medical College, Fudan University, Shanghai, ChinaCenter for Biomedical Imaging, Fudan University, Shanghai, ChinaShanghai Engineering Research Center for Molecular Imaging Probes, Shanghai, CHINA

Aim: Prostate-specific membrane antigen (PSMA) is a well-established target for developing radiopharmaceuticals for imaging and therapy of prostate cancer (PCa). We have synthesized an amino-functionalized PSMA inhibitor(Lys-Urea-Glu) and labeled technetium-99m via HYNIC. The in vivo target capacity of the new molecular imaging pobe was evaluated in animal model and compared with ^{18}F-FDG and ^{11}C-Choline which were the mostly used in clinical.Material and method: The small-molecular inhibitor was based Lys-Urea-Glu core which linked ^{99m}Tc chelator HYNIC through 6-aminocaproic acid. We assessed the new molecular imaging probe in SCID mice bearing PC-3 and LNCaP tumor xenografts on Nano-SPECT/CT. The comparative experiment of ^{18}F-FDG and ^{11}C-Choline imaging was done in the LNCaP tumor xenografts on Micro-PET/CT. The T/B data was obtained by the analysis software accompanying with Nano-SPECT/CT and Micro-PET/CT respectively.Results and conclusion: The imaging results showed that the metabolism of the radioactive probe ^{99m}Tc-HYNIC-Acs-Lys-Urea-Glu was very fast. Kidney was the primary excretory organs and little radioactive uptake was found in intestines. There were no significant uptake in other organs. The PC-3 tumor doesn't have any radioactive uptake, the LNCaP tumor had very high radioactive uptake and the T/B (tumor to muscle) was 20.4. The blocking experiment that the probe was blocked by the excessive 2-PMPA on LNCaP tumor xenografts showed that the tumor uptake reduced significantly. This illuminated the probe exactly targeted PSMA. The T/B data obtained from the PET/CT imaging were 2.1 and 2.6 for ^{18}F-FDG and ^{11}C-Choline respectively which was much less than ^{99m}Tc-HYNIC-Acs-Lys-Urea-Glu.The probe ^{99m}Tc-HYNIC-Acs-Lys-Urea-Glu with fast metabolism and high tumor uptake was a promising molecular imaging probe targeted PSMA. It was superior to ^{18}F-FDG and ^{11}C-Choline in PCa.

PW068

Preclinical evaluation of selected 68Ga labelled peptides for glioblastoma imaging

M. Petrik[1], J. Stepankova[1], Z. Crlikova[1], R. Trojanec[1], J. Drymlova[2], M. Hajduch[1], Z. Novy[1]; [1]Faculty of Medicine and Dentistry, Palacky University Olomouc, Olomouc, CZECH REPUBLIC, [2]Department of Nuclear Medicine, University Hospital Olomouc, Olomouc, CZECH REPUBLIC.

Aim: Glioblastoma multiforme (GBM) is the most aggressive type of primary brain tumors in humans with more than 90% 5-year mortality. Early diagnosis may be the key factor for improving patient survival rates through the prevention of tumor growth. Radiolabelled regulatory peptides continue to hold promise for early diagnosis of many human diseases, including GBM. Here we report on the preclinical evaluation of two 68Ga labelled peptides as potential agents for GBM imaging and in vivo comparison with clinically used 18F labelled radiopharmaceuticals. Materials and methods: 68Ga labelling of selected peptides (NODAGA-cRGDyK dimer and DOTA-substance P) was performed in acetate buffer using fractionated method. The labelling

conditions were optimized concerning temperature, peptide amount and reaction time. For in vitro characterization, partition coefficient, protein binding properties and stability values in different media were determined. Ex vivo biodistribution and PET/CT imaging was studied in normal Balb/c and tumor (U87MG) Balb/c nude mice. Results: Both peptides were labelled with 68Ga with high radiochemical purity (>95%). 68Ga-NODAGA-cRGDyK dimer showed hydrophilic properties and was stable in vitro in human serum, concentrated iron(III) and DTPA solutions as well as at pH = 7 and in vivo. In contrast, 68Ga-DOTA-substance P displayed much lower in vitro stability, especially in concentrated iron(III) and DTPA solutions and was rapidly metabolized in vivo. Protein-bound activity of 68Ga-NODAGA-cRGDyK dimer after 120 min incubation (3.9%±1.9) was found to be 7-fold lower than for 68Ga-DOTA-substance P. In normal mice, both 68Ga labelled tracers revealed mainly renal elimination with low blood values (0.10±0.01%ID/g RGD and 0.28±0.03%ID/g S-P) 90 min p.i., while 18F-FLT and 18F-FDG showed much slower kinetics and not only renal, but also gastrointestinal excretion. Moreover 18F-FDG displayed significant radioactivity retention in metabolically active tissues (brain, brown adipose tissue and heart). In tumor mice, 68Ga-NODAGA-cRGDyK dimer was highly accumulated in tumor (5.59±2.10%ID/g, 30 min p.i. and 3.13 ±0.79%ID/g, 90 min p.i.), whereas metabolically degraded 68Ga-DOTA-substance P showed much lower accumulation in tumor (2.14±0.17%ID/g, 30 min p.i. and 0.72±0.04%ID/g, 90 min p.i.). In comparison with 18F-FLT and 18F-FDG, 68Ga-NODAGA-cRGDyK dimer revealed more favourable pharmacokinetics and comparable accumulation in tumor confirmed also by μPET/CT. Conclusion: Studied peptides bound 68Ga with high affinity, and 68Ga-NODAGA-cRGDyK dimer, especially, displayed high stability and excellent pharmacokinetics. Moreover 68Ga-NODAGA-cRGDyK dimer showed superior in vivo properties compared to 18F-FLT and 18F-FDG, while maintaining a similar uptake in tumor. 68Ga-NODAGA-cRGDyK dimer seems to be a promising agent for glioblastoma imaging.

PW069

Preclinical evaluation of two DOTA-coupled minigastrin analogues (Met and corresponding Nle congener)

M. Kroselj[1], L. Claessens Joosten[2], R. Mansi[3], J. Reubi[4], H. Maecke[3], P. Laverman[2], O. Boerman[2], P. Kolenc Peitl[1]; [1]Department of Nuclear Medicine, UMC Ljubljana, Ljubljana, SLOVENIA, [2]Department of Radiology and Nuclear Medicine, Radboud University Medical Center, Nijmegen, NETHERLANDS, [3]Department of Nuclear Medicine, University Hospital Freiburg, Freiburg, GERMANY, [4]Division of Cell Biology and Experimental Cancer Research, Institute of Pathology, University of Berne, Berne, SWITZERLAND.

Aim: The stability of the minigastrin analogues is highly influenced by the charge and the stereochemistry of the amino acid sequence constituting the spacer. It was recently shown that introduction of non-ionic (6 D-Gln) or ionic (6 D-Glu) D-amino acid spacers results in remarkable improvement in metabolic stability. The analogue with the ionic D-Glu spacer showed the best in vitro and in vivo properties and was chosen as the most suitable tracer for phase I clinical study for diagnosis and therapy of MTC patients. The aim of this work is to evaluate the properties of a new analogue, PP16(Met11), having as spacer the sequence of the mixed ionic/non-ionic amino acids $(D\text{-}Gln\text{-}D\text{-}Glu)_3$. Since it is well known that methionine is prone to oxidation that can significantly influence the binding affinity, the Nle congener PP16B(Nle11) was developed for comparison. We radiolabeled two DOTA-conjugated minigastrin analogues with ^{111}In under same reaction conditions and compared their in vitro and in vivo characteristics. Material and Methods: The minigastrin analogues (DOTA-$(D\text{-}Gln\text{-}D\text{-}Glu)_3$-Ala-Tyr-Gly-Trp-Met/Nle-Asp-Phe-NH2) were synthesized manually on solid phase. CCK-2R affinities were determined by receptor autoradiography using ^{125}I-CCK as radioligand. ^{111}In-labeled peptides were evaluated in vitro in AR4-2J cell line and in human serum. In vivo behaviour was studied using female athymic BALB/c mice with s.c. A431-CCK2R tumors. SPECT imaging was performed at 1h and 4h p.i and organs, blood and tissues of interest for biodistribution were collected 4h p.i. Results: Both peptides showed high binding affinity to the CCK-2/gastrin receptor with IC_{50} values in low nM range (0.5±0.06 Nle11 and 0.5 ±0.1 Met11). Nle11 showed higher receptor-specific internalization (15.1±0.8% vs. 10.4±0.9% at 4h), but lower enzymatic stability in human serum (85±68 vs. 141±68 h). Tumor uptake at 4h p.i. for Nle11 was 2.06±0.86%ID/g and 1.22±0.66%ID/g for Met11 (p=0.111). Tumor retention of Nle11 was 82.2% at 4h and 90.02% of Met11 (p=0.271). Conclusion: Two DOTA-coupled minigastrin analogues with the same mixed ionic/non-ionic spacer and alteration in C-terminal part (Met/Nle) were developed. Changing the natural Met for Nle had no influence on binding affinities of these molecules to CCK-2R. In addition, the replacement had no significant effect on tumor and kidney uptake. Both radiolabeled peptides demonstrate good tumor retention of radioactivity. We showed that both analogues have similar in vivo characteristics. Since Nle11 is not oxidized during the radiolabeling with radiometals, the radiolabeling step is more straightforward and thus making the Nle11 a better candidate for a possible clinical use.

PW070

Auger Electron Radioimmunotherapy with ^{111}In-Bn-DTPA-Nimotuzumab Inhibits the Growth of EGFR-Positive Human Breast Cancer Tumours in Mice at Doses that are Non-Toxic to Normal Tissues

C. Chan[1], H. Fonge[1], K. Lam[1], R. Reilly[1,2,3]; [1]Department of Pharmaceutical Sciences, University of Toronto, Toronto, ON, CANADA, [2]Department of Medical Imaging, University of Toronto, Toronto, ON, CANADA, [3]Toronto General Research Institute and Joint Department of Medical Imaging, University Health Network, Toronto, ON, CANADA.

Aim: To evaluate the tumour growth inhibition properties and normal tissue toxicity of Auger electron radioimmunotherapy (RIT) of human breast cancer xenografts overexpressing EGFR in CD1 athymic mice using ^{111}In-Bn-DTPA-nimotuzumab. Methods: Normal tissue toxicity was first evaluated in non-tumour bearing mice following i.v. injection of 8.8 or 28.2 MBq (3 mg/kg) of ^{111}In-Bn-DTPA-nimotuzumab. Control mice were treated with unlabeled Bn-DTPA-nimotuzumab or normal saline. The body weight index (BWI) was determined every few days by dividing the body weight by that prior to treatment. Complete blood cell counts (CBC), hematocrit and hemoglobin, and serum alanine aminotransferase (ALT) and creatinine (Cr) were measured at 2 weeks p.i. RIT was then performed in CD-1 athymic mice bearing s.c. MDA-MB-468 human breast cancer xenografts (1 x 10^6 EGFR/cell) by administering two doses i.v. (15.5 MBq; 3 mg/kg) of ^{111}In-Bn-DTPA-nimotuzumab separated by two weeks. Control mice were treated with unlabeled Bn-DTPA-nimotuzumab, irrelevant ^{111}In-Bn-DTPA-trastuzumab or normal saline. The tumour growth index (TGI) was determined weekly by dividing the tumour volume at selected time points by that prior to treatment. The slope of the TGI vs. time curve was calculated for each group. BWI was also measured. Results: ALT levels in non-tumour bearing mice injected with 8.8 or 28.2 MBq of ^{111}In-Bn-DTPA-nimotuzumab were 32.8±5.0 or 77.3 ±31.9 U/L, respectively, compared to 29.8±4.3 or 24.8 ±6.3 U/L in mice receiving unlabeled Bn-DTPA-nimotuzumab or saline, respectively ($p>0.05$). Cr in mice injected with 8.8 or 28.2 MBq of ^{111}In-Bn-DTPA-nimotuzumab were 63.3±33.9 or 128.6±71.7 μmol/L, respectively, compared to 22.1±14.5 or 24.5±10.0 μmol/L in mice administered unlabeled Bn-DTPA-nimotuzumab or saline, respectively ($p>0.05$). No differences in BWI were noted for any groups. There was no effect of 8.8 MBq of ^{111}In-Bn-DTPA-nimotuzumab on CBC but leukocyte counts were lower for mice administered 28.2 MBq (3.5 ±0.6 K/μL) compared to saline treated mice (8.2±0.9 K/μL; P=0.012). An intermediate dose of 15.5 MBq of ^{111}In-Bn-DTPA-nimotuzumab was selected for RIT. The slope of the TGI vs. time curve over 84 days was lower ($p<0.05$) for tumour-bearing mice treated with two doses (15.5 MBq each) of ^{111}In-Bn-DTPA-nimotuzumab (0.010 ±0.005 d^{-1}) compared to mice injected with unlabeled Bn-DTPA-nimotuzumab (0.064±0.011 d^{-1}), irrelevant ^{111}In-Bn-DTPA-trastuzumab (0.049±0.010 d^{-1}) or normal saline (0.066±0.010 d^{-1}). There was no difference in BWI among the groups. Conclusion: ^{111}In-Bn-DTPA-nimotuzumab is a promising new treatment for EGFR-overexpressing breast cancer. Supported by a grant from the Canadian Institutes of Health Research. Nimotuzumab was provided by YM Biosciences, Inc.

PW071

Bone scan and MRI in Chronic Recurrent Multifocal Osteomyelitis

L. Biassoni; Great Ormond Street Hospital for Children NHS Foundation Trust, London, UNITED KINGDOM.

Aim: Chronic Recurrent Multifocal Osteomyelitis (CRMO) is a rare inflammatory bone disorder presenting with relapsing and remitting episodes of bone pain. MRI is the imaging modality of choice; however, long waiting lists often prevent patients to have access to MRI in a timely fashion. Aim of this study was to compare the diagnostic yield of the bone scan (BS) versus MRI in CRMO and to correlate the findings with inflammatory markers and clinical symptoms/location of pain. Materials and Methods: Retrospective review of the clinical notes of children with a confirmed diagnosis of CRMO who had both bone scan and MRI between 2009 and 2014, and within 9 weeks of each other. Nine patients (7 females, 2 males, age range 7-13 years, mean 9.6) had both BS and MRI less than 9 weeks apart. We recorded for each patient: inflammatory markers at time of scans (ESR, CRP and WCC), clinical symptoms, pain location, number and location of lesions for BS and MRI. Patients were excluded if BS and MRI were done more than 9 weeks apart, or if there was any change to treatment in-between scans. BSs were acquired as a whole body sweep, with high count spot views of the areas of interest and SPECT CT when necessary. MRI scans were limited to the area of interest (only 1 patient had whole body MRI) and were acquired using T1, T2, and STIR sequences (and contrast enhanced in 6 patients). Results: Pain was always associated with a bone lesion on imaging. BS was always

positive at the site of symptoms. MRI consistently detected more lesions than BS (45 lesions versus 31 with BS), especially in the spine. However, several lesions, mainly suggestive of bone marrow oedema, were asymptomatic, and their clinical significance was questionable. BS was better at detecting rib lesions. MRI and BS were concordant in 69% of cases. The inflammatory markers were non-specific. Conclusion: MRI and BS were concordant in a high number of cases. MRI detected more lesions than BS; however, several lesions were asymptomatic and of doubtful clinical significance. BS was always positive at the site of symptoms. BS can be considered in CRMO if MRI is not readily available.

PW072

Scintigraphic functional evaluation of intrathecal drug infusion devices

G. Garraffa[1], V. Scaglione[2], F. Felice[1], R. Ricapito[1]; [1]Nuclear Medicine Unit, A.R.N.A.S. "Ospedale Civico, Di Cristina e Benfratelli", Palermo, ITALY, [2]Neurosurgery Unit, A.R.N.A.S. "Ospedale Civico, Di Cristina e Benfratelli", Palermo, ITALY.

Scintigraphic evaluation of intrathecal drug infusion devices.GARRAFFA G.1, SCAGLIONE V.2, FELICE F.1, RICAPITO R.1 AND ARNONE G.1.1 Nuclear Medicine Unit, A.R.N.A.S. "Civico, Di Cristina e Benfratelli", Palermo, Italy. 2 Neurosurgery Unit, A.R.N.A.S. "Civico, Di Cristina e Benfratelli", Palermo, Italy.Introduction and aim: intrathecal infusion devices are used for pts. with pain and spastic diseases. These are made by a pump with a reservoir for the drug allocated in the abdominal subcutaneous space and connected to a catheter ending in the spinal subaracnoid space. Malfunctioning of the infusion system or progression of pain disease causes increasing infusion rates or drug amount. Administration of a not-absorbed radionuclide (99mTc-DTPA) in the pump reservoir and sequential scanning allow to follow the progression of the radionuclide along the catheter to the spine. The images show any interruption/delay of the system radionuclide progression and, if the flow rate of the pump device is programmable, quantitative evaluation of the flow itself along system. Aim: to evaluate the effectiveness of 99mTc-DPTA infusion within the device in order to detect malfunctioning and to correlate the results with patient management and outcome.Methods: 8 patients already studied with 99mTc-DTPA scintigraphy were retrospectively reviewed. All of them had surgically implanted Medtronic® SynchroMed intrathecal (baclofen or ziconotide) infusion pump systems, because of severe spasticity (n=5) or intractable pain (n=3). About 400 MBq 99mTc-DPTA was injected into the pump reservoir, then planar serial static abdominal scans were performed every three hours for 24 hours to follow tracer progression. Once the tracer arrived in the spinal liquoral system, whole-body scans were performed.Results: no adverse effects on heat conditions correlated with 99mTc-DPTA were registered. 1 pt. showed regular device functioning without interruption of progression and with delivery flow corresponding to the programmed flow. 6 pts. showed interrupted progression along the abdominal portion of the catheter, one of which also with subcutaneous dispersion of the radionuclide. 1 pt. showed quantitative alteration of the flow rate, too slow respect to the programmed delivery flow rate. Pts. with flow stop were re-operated and operative findings confirmed the scintigraphic data. Patient with flow reduction presented pump failure, while pt. with normal flow had psychiatric disorders.Conclusions: intrathecal infusion system scintigraphy is an useful tool in non-invasive evaluation of functioning of implants with programmable pump. Use of 99mTc-DPTA radionuclide allows satisfactory and good-quality study conduction, without any adverse effects and with lower dosimetric load than 111In-DTPA.

PW073

99mTc-HDP bone SPECT with voxel-based evaluation for temporomandibular asymmetry detection in diagnosis of the idiopathic condylar hyperplasia

D. Chroustova, J. Sebek, J. Trnka, J. Kubinyi; General University Hospital and 1st Faculty of Medicine Charles University, PRAGUE 2, CZECH REPUBLIC.

Aim: Idiopathic condylar hyperplasia (ICH) is characterized by persistent or accelerated growth of the mandibular condyle, when growth should be slowing or ended. 99mTc-HDP bone SPECT and voxel-based mathematical analysis is used to verify the activity of condylar growth. The aim of the study was to verify temporomandibular asymmetry in diagnosis ICH and according the results to choose suitable surgery: condylar shaving or conventional orthognathic surgery. Treatment of patients with active condylar growth only with classical orthognathic surgery methods could lead to relapse of asymmetry. Materials and methods:106 patients (67 female a 39 male) aged 13-47 (average 21) years with laterogenia underwent bone SPECT with the right to left ratio assessment of the temporomandibular joints (TMJ) uptake using the voxel-based method. 18 patients were investigated repeatedly. Bone SPECT was performed 2-3 hours after injection of 300-700MBq 99mTc-HDP on dual-heads gamma camera Infinia GE using a low-energy, high-resolution collimator, with following acquisition parameters:120 projections, 20sec/projection, matrix 128x128. Voxel-based analysis of the right to left TMJ uptake ratio: The VOIs of the temporomandibular joints were defined using a combination of two spatial voxel masks. One mask was defined via an intensity threshold and served to

separate out the background. The other mask was defined by an origin and a radius and served to separate out objects outside the corresponding sphere. An intersection of these two masks defined desired volume of interest. Total counts from each corresponding VOI came without background correction as inputs to the default formula: L=NL/(NR+NL).100%, R=NR/(NR+NL) .100%. For the evaluation we considered 10% difference (in terms of percentage points) of 99mTc-HDP uptake between mandibular condyles as a sign of active ICH. Results: 44 subjects had uptake difference higher than 10%. These scans confirmed indication of 36 patients for condylar shaving to stop the condyle growth. Additional orthognathic surgery for fine-correction of asymmetry was needed in 7 patients and in 14 cases dental compensation of occlusion was sufficient treatment. 85 subjects had uptake difference 10% or lower. These results disproved working diagnosis of ICH in 70 patients and in 26 cases conventional orthognathic surgery was performed. No relapse was wound within 2 years postoperatively. Conclusion: 99mTc-HDP bone SPECT with voxel-based evaluation of the mandibular condyle accelerated growth is crucial in diagnosis of ICH. Finding with an asymmetrical TMJ growth is indicated to treatment with condylar shaving in the first phase and orthognathic surgery later.

PW074

Assessment of ACL Graft Viability by Dynamic FDG PET: A Phase I Study

K. Binzel[1], R. Magnussen[1], C. Kaeding[1], W. Wei[1], M. U. Knopp[2], D. C. Flanigan[1], M. V. Knopp[1]; [1]The Ohio State University Wexner Medical Center, Columbus, OH, UNITED STATES, [2]Pepperdine University, Malibu, CA, UNITED STATES.

In cases of a complete tear, injury to the anterior cruciate ligament (ACL) typically requires reconstruction with a graft. Patients having received a graft are at risk of re-injury, with no available imaging methodologies to assess ligamentization of the graft. In a first-in-human study, we demonstrate the capability of a combined imaging approach using dynamic, ultra-low dose positron emission tomography (PET) and MRI for evaluation of graft healing following reconstructive surgery. 20 patients post-ACL graft reconstruction had dynamic PET on a Gemini TF 64 and/or new digital detector PET/CT system, Vereos TF. An in-house constructed foam cushion was used to place both knees in matched positions to that of the dedicated MR knee coil during PET acquisitions. Using an ultra-low dose (<111 MBq) 18F-fluorodeoxyglucose (FDG) protocol, a single bed position centered on the knees was acquired continuously for 75 minutes. Standard of care MRI was performed on a Philips 3T Achieva (all systems Philips Healthcare, Cleveland, OH). PET images were co-registered to MRI for quantification. Standardized uptake values (SUV) were measured for regions of interest (ROI) in the proximal, middle, and distal portions of the graft, the tibial and femoral tunnels, the posterior cruciate ligament (PCL), and the quadriceps muscle for reference. Matched measurements were taken in each contralateral knee. The slope of the enhancement curve over the 75 minute acquisition was calculated for each ROI. Patients were grouped according to time since surgery, from 0-6 months, 6-12 months, 12-24 months and 24+. Dynamic PET images were readily co-registered to MRI for all patients. In the 0-6 month group the average slope of the metabolic uptake curve was 0.20 in the distal graft, 0.21 in the mid graft, 0.27 in the proximal graft, and 0.14 in the tibial tunnel. In contralateral healthy knees the average slopes were 0.06, 0.09, 0.05, and 0.05, respectively. These healthy values were similar to measurements seen in the 12-24 and 24+ month groups. Patients with longer healing times were also found to have absolute SUVs increasingly approaching healthy values as well. Quantitative evaluation of ACL graft ligamentization using an ultra-low dose PET protocol with co-registration to MRI was demonstrated. The digital PET enables even further dose reductions with improved image quality and quantitative accuracy. A combined low dose FDG PET/MRI exam to assessment of ACL graft healing appears to promising tool.

PW075

High Therapeutic Impact in New Indications of 18F-FDG PET/CT in High/Intermediate Recurrence Risk Differentiated Thyroid Carcinoma Patients

E. M. Triviño-Ibáñez[1], M. A. Muros[1], E. Torres-Vela[2], J. M. Llamas-Elvira[1]; [1]Virgen de las Nieves University Hospital, Granada, SPAIN, [2]San Cecilio University Hospital, Granada, SPAIN.

INTRODUCTION: Little is known about clinical benefits and the therapeutic impact of fluorine-18-fluorodeoxyglucose positron emission tomography/computed tomography (18F-FDG PET/CT) performed early after radioactive iodine (RAI) ablation in differentiated thyroid carcinoma (DTC). AIM: Investigate whether 18F-FDG PET/CT performed early after RAI ablation is useful in detection of disease and influence therapy in new indications of high/intermediate risk of DTC. PATIENTS and METHODS: A prospective study was carried out (June 2007 to December 2013) on 81 patients with high/intermediate risk of recurrence differentiated thyroid carcinoma, treated with surgery and radioidine ablation. Our patient selection was not based exclusively on TNM classification and included broad risk criteria (ATA guidelines 2009, etc.) [8], such as locoregional invasion, inadequate high Tg value and aggressive histological subtypes.Demographic data,

surgery and pathology report, neck ultrasound and 131I-whole body scan results and biochemical test lab report were collected. We performed 18F-FDG- PET/CT just before or inmediately after surgery. We confirmed 18F-FDG- PET/CT results with other imaging techniques, pathology report, first year whole body scan, neck ultrasound or follow-up. We used modified Hicks criteria for evaluate 18F-FDG- PET/TC results impact. RESULTS: 81 patients with high/intermediate-risk of recurrent DTC. Forty-one (50.6%) had positive uptake in 18F-FDG PET/CT, with negative 131I WBS. Sensitivity, specificity and diagnostic accuracy of PET/CT were 92.5%, 90.2% and 91.4% respectively. PET/CT results had an impact on therapy in 38.3% of patients. One year after initial therapy, 45.7% showed excellent response, 8.6% acceptable and 45.7% incomplete response. We found statistically significant relationship between negative PET/CT and excellent response (80 vs. 12.2%, p <0.001; OR: 52.8). CONCLUSIONS: 18F-FDG PET/CT performed early in surveillance of high/intermediate-risk thyroid carcinoma provides information fundamental to patients follow-up. A wide patient selection of high/intermediate risk DTC improves 18F-FDG PET/CT results and determines a high therapeutic impact.

PW076

17 years follow-up from 1998 to 2015 of 123 medium-size (2-4 x normal) EU-and Hyperthyroid (EU, HT) goitres after treatment by 131I (RIT)

C. ALS, N. LENERS; Hôpitaux Robert Schuman - Zithaklinik, Luxembourg, LUXEMBOURG.

OBJECTIVE: We present a long-time follow-up of patients (pat) with medium-size goitres (2-4x normal), (normal = ♀:18 mL, ♂:25 mL) treated by RIT in a reference centre. MATERIALS AND METHODS: (med=median, mima=min-max, ↓=decreased, <0.0005=*). Out of 673 patients treated by 131I (1998-3.2010), 123 pat (92♀, 27-90 (med 69) years (Y) and 31♂, 22-83 (med 70) Y), with a medium-size goitre by ultrasound (♀:36-72mL, ♂:50-100mL, 6 pat excluded (1 emigration/ 5 Basedow post-131I)), were followed until 03.2015, i.e., 0.9-8.8 Y post-131I (mean/med 4.1/3.9 years). Simulation was at 6h/24h/100h: calculation (MIRD, 100-300 Gy), therapeutic activity 131I (370-1295MBq, mean/med 785/800MBq). Out of 123 pat: 10 had HT Basedow (B) (med TSH 0.01 mU/L), 18 had EU goitre (med TSH 1.03 mU/L), 95 had HT functional autonomy (FA, med TSH 0.12 mU/L). RESULTS : At 4 months (mo)/1Y/endpoint, thyroid (T) vol had resp.↓ by 41.3%/55.2%/61.9% (all*), without a ♀-♂difference. Vol. normalisation 1 Y post-RIT was found in ♀41%, ♂32%. At 4 mo/1 Y, TSH: (B) 40.0/15.8 mU/l (p=0.4), EU goitre 2.52/1.88mU/L (p=0.48), FA 1.03/1.25mU/L (p=0.008). 81% pat were EU at 1Y (♀: 83%, ♂: 74%). RIT was repeated with 2 pat. Death occurred in 24 pat (survival 9-148.8 mo, med 70 mo). Clinically better subjective feeling after 12 mo in 100% pat. Hormone substitution was required in 10%/45%/61.5% of pat after 4mo/12mo/endpoint. Thyroid volumes before RIT (Mima=36-98mL, mean=55.7mL, med=52mL) were respectively at 4mo (6-78mL, 33.51mL, 30mL*), at 1Y (2-75mL, 27.31mL, 25mL*), at >1Y (2-100ml, 21.4ml, 17mL*), in ♀med respectively (50mL, 28ml*, 22ml*, 14mL*), in ♂med respectively (68.5mL, 41.5mL*, 32.5mL*, 32mL*). TSH value before RIT respectively was (0-5.4mU/L, 0.5mU/L, 0.2mU/L), at 4mo (0-89mU/L, 5.2mU/L, 1.1mU/L), at 1Y (0.1-72mU/L, 3.7mU/L, 1.5mU/L), at >1Y (0.1-36mU/L, 2.33mU/L, 1.49mU/L). Med TSH changes in ♀ and ♂ were ns. CONCLUSIONS: Compared with other thyroid pathologies, ♂ have relatively more goitres 2-4x normal than ♀. RIT is a safe and efficient method for thyroid vol ↓ and HT eradication, equally efficient with ♀ and ♂. HypoT and need for hormonal supply increases with time after RIT. Vol ↓ significantly proceeds over several years. Volume change after RIT was equally efficient in ♀ and ♂.

PW077

The Clinical Outcome and Mortality Rates in patients with Differentiated Thyroid Carcinoma with bone metastasis: Results of a 15- year clinical follow-up.

G. Ucmak, B. Demirel, **B. E. Akkas**, A. K. Fidan, N. Ercakmak; Ankara Oncology Research and Training Hospital Department of Nuclear Medicine, Ankara, TURKEY.

In this study, we evaluated the treatment response and clinical outcome of Differentiated Thyroid Carcinoma (DTC) patients with bone metastases. Method: DTC patients treated in our department from 1990 to 2014 were retrospectively evaluated, 43 patients with bone metastasis were included in this study (28 F, 15 M, mean age: 53 years). All patient records, treatment history, laboratory and clinical information were evaluated. The final status of the patients was defined according to clinical follow-up data. The total follow-up time ranged from 13 to 178 months (median: 65 months). Results: 43 patients (21 papillary, 18 follicular, 3 poorly differentiated, 1 Hurthle cell carcinoma) were included. Thirty-five patients (81%) had bone metastasis at the time of diagnosis whereas 8 patients were progressed with bone metastasis. All patients had elevated serum Thyroglobulin (Tg) levels (>500 ng/ml with TSH stimulation) at the time of diagnosis. Twenty-seven patients (63%) had multiple sites of bone metastasis. Fourteen patients had organ metastasis (33%) as well. 4 patients underwent surgical resection for metastatic foci. Inoperable iodine-

avid metastases are treated with multiple administrations of radioiodine with empirical activities of 200-250 mCi each. The cumulative doses were ranged from 200 to 1600 mCi. Twenty-six patients (60%) received external radiation therapy. The response of therapy was evaluated with serum Tg levels, anti-Tg antibody levels and radioiodine body scans. The final status of patients was defined on the basis of a long term follow-up, up to 178 months. Five patients (12%) had complete biochemical and clinical remission, 13 patients (35%) had partial remission with significant drop in serum Tg levels. Two patients had stable disease. Six patients had progressive disease, 17 patients (40%) were died of disease on follow-up. The time to exitus ranged from 1-to-11 years with a mean of 4.8 years after the diagnosis of metastatic disease. All patients with disease specific mortality had organ and multiple sites of bone metastasis mostly located on the vertebral colon. The main cause of mortality was the complications arisen from spinal cord compression due to tumoral involvement. Results: Bone metastases of DTC have poor prognosis. The mortality rate was 40% in our series. We observed that, mortality was higher in patients with vertebral colon metastasis. However, our results showed that, with combined and intensive treatment modalities, up to 12% of complete remission, 35% of good therapeutic responses and partial remission can be achieved, the quality of life can be improved.

PW078

Evaluation of a fast and a standard protocol for bone scintigraphy SPECT/CT in patients suspected for having bone metastasis

K. Knudsen, A. Bekker, S. Jentoft Kramer, P. Iversen, A. Arveschoug; Aarhus University Hospital, Noerrebrogade, AARHUS, DENMARK.

Background: Bone scintigraphy including SPECT/CT compared to wholebody scintigrams has been shown to increase the specificity, to a minor extent the sensitivity, and observer confidence in the evaluation of bone metastasis in cancer patients. Several studies have demonstrated that the proportion of indetermined bone lesions can be reduced significantly by using SPECT/CT. In order to optimize the examination time as well as the fact that many patients with bone metastasis have difficulties lying still for longer periods of time, has prompted us to optimize our bone scintigraphy SPECT/CT protocol. Aim: To evaluate whether a fast SPECT protocol could substitute the standard SPECT protocol for SPECT/CT bone scintigraphy. Methods: Thirty patients referred for bone scintigraphy, 28 suspected for having bone metastasis, were included in the study. All patients were injected with a standard dose of 99mtechnetium-labeled diphosphonate (Teceos, DPD) and had a planar wholebody scan. In each of the three regions head-neck-thorax, mid trunc and pelvic-proximal femoral area, 10 patients were scanned twice with a fast and standard SPECT/CT protocol, respectively, on a Siemens Symbia T16 SPECT/CT camera (Siemens AG, Erlangen, Germany). The fast protocol in a continuous mode and total scan time of 31 minutes for the trunc, the standard protocol in a step and shoot mode and total scan time of 50 minutes for the trunc. Three independent observers analyzed the standard and fast SPECT/CT over each region, anonymized and randomized. All foci in each region were scored on a 5-point scale as normal lesion, probably normal lesion, equivocal lesion, probably malignant lesion or malignant lesion. The wholebody scans were evaluated accordingly. Results: Independent of both observer, region and nature of foci, the total number of foci detected on the wholebody scan were considerably lower compared to both standard and fast SPECT/CT. Furthermore, the data showed a trend towards a lower total number of detected foci in the fast SPECT/CT protocol scans compared to the standard protocol scans. The difference were more pronounced in the mid trunk region, although not significant for any of the three observers in any of the three regions ($p > 0.05$). Conclusion: In this study we found no significant differences in the observers ability to detect and describe the bone pathology in a fast and a standard SPECT/CT bone scintigraphy protocol, respectively. However, the limited population size of the current study may increase the variability of the data to produce a false-negative difference.

PW079

Nephrotic Syndrome with pulmonary embolism: the role of lung scintigraphy

i. G. E. el bez, A. EZZINE, B. LTAIEF, I. SLIM, D. BEN SELLEM, l. zaabar, I. MEDDEB, I. YEDDES, b. dhaoudi, A. MHIRI, M. BEN SLIMENE; institut salah azaiez, tunis, TUNISIA.

Patients with nephrotic syndrome (NS) have an increased tendency to develop thrombosis and even to progress to pulmonary embolism (PE).This study was performed to determine the incidence of PE in NS and to evaluate the role of perfusion lung scans in these patients.Materiel and methods: Thirty-four patients with NS and risk factors for PE were studied. Eight patients had a renal failure. In all patients, the probability of PE was assessed based on the results of perfusion lung

scans (Tc-99m MAA). The perfusion scan was repeated in patients having a PE. The lung scans were judged using the modified Prospective Investigation of Pulmonary Embolism Diagnosis criteria. The patients' clinical symptoms and signs on initial examination were reported. Additional examinations included electrocardiograms, chest radiography, and biological tests such as creatinine, albuminemia.Results: Based on the findings of lung scans, 22 (64.7 %) of the patients were categorized as having a high probability of PE. 12 (35.3%) patients had a normal perfusion lung scan. CT angiography was performed in 26 patients and showed the same results that lung scan.Two weeks after the administration of intravenous heparin for anticoagulative therapy, twenty cases had a recovery or an improvement.Conclusion: The results of this study suggest that PE is not a rare complication in patients with NS. The occurrence of PE did not appear to be always correlated with the clinical or biological severity of NS. Perfusion lung scans may provide valuable clues in the evaluation of these patients.

PW080

Lung V/Q scintigraphy and perfusion SPECT in the diagnosis of chronic thromboembolic pulmonary hypertension

J. A. MARROQUÍN GÁLVEZ, D. SANCHEZ FUENTES, A. SAVIATTO, A. C. HERNANDEZ MARTINEZ, J. P. PILKINGTON WOLL, M. J. TABUENCA MATEO, S. RUIZ SOLIS, J. M. ESTENOZ ALFARO; HOSPITAL UNIVERSITARIO 12 DE OCTUBRE, MADRID, SPAIN.

AIM: To evaluate the efficacy of lung ventilation/perfusion (V/Q) scintigraphy and perfusion SPECT in the initial screening of Chronic Thromboembolic Pulmonary Hypertension (CTEPH). MATERIALS AND METHODS: Retrospective study including 32 patients (9 male and 23 female), with age ranging from 23-82 years (54.56 ± 19.12), with suspected diagnosis of CTEPH, referred by the CTEPH unit of our hospital, between April and December 2014.Lung V/Q scans were performed using 99mTc-Technegas and 99mTc-MAA (Macroaggregated Albumin) respectively, including anterior, posterior and right and left posterior oblique projections. Perfusion SPECT was also acquired in all of them.EANMMI guideline criteria (positive, negative or indeterminate) was applied when reporting the findings.CT pulmonary angiography and/or thoracic CT was also performed to all patients as part of the study.Pulmonary angiography by right heart catheterization was used as the gold standard for the final diagnosis. RESULTS: Twenty one out of 32 patients were diagnosed of CTEPH by pulmonary angiography. Planar lung V/Q scan and perfusion SPECT were positive in 23/32 patients (2 false positive for Primary Pulmonary Hypertension). The other 9/32 patients were reported as negative. We did not obtain any false negative or indeterminate result.The V/Q scan and perfusion SPECT for the diagnosis of CTEPH had a sensitivity of 100%, specificity of 81.82%, positive predictive value of 91.30%, negative predictive value of 100%, and an accuracy of 93.75%. CONCLUSION: In our study, lung V/Q scan and perfusion SPECT had a high sensitivity and negative predictive value for CTEPH diagnosis with an accuracy value around 95%, demonstrating their strong efficacy in the initial screening of CTEPH.

Sentinel node detection with ferromagnetic particles in breast cancer. Preliminar results

U. Granados, S. Vidal-sicart, X. Caparrós, M. Alonso, P. Fernandez, P. Perlaza, A. Tápias, F. Lomeña; Hospital Clínic, Barcelona, SPAIN.

Aim: To compare two techniques for sentinel lymph node (SLN) detection in patients with breast cancer (BC): radioactive tracer (99mTc-Nanocoll®) and ferromagnetic particles (SentiMag®) and to analyze the correlation between two different injection sites and time spent for SLN location. Material and Methods: We have studied prospectively 29 BC patients, scheduled for SLN Biopsy, with a mean age of 60.7 years. The injection of the radiotracer (111 MBq in 0.5 mL) was mainly intra / peritumoral the day before surgery. Lymphoscintigraphic images (30 min and 2 h) were subsequently performed. No external mark in SLN skin projection was drawn. In the operating room, 5 ml of ferromagnetic particles (Sienna+®) were administered by periareolar injection followed by a 5 minutes massage. The surgeon used a magnetometer and the nuclear medicine physician used the gamma radiation detection probe. The transcutaneous signal was evaluated with SentiMag (surgeon) and with gamma probe (nuclear medicine physician).The skin incision was performed after reaching a clear transcutaneous signal with SentiMag®. The correlation between the magnetic source and the radioactivity was checked. Results: In 26 patients was located at least one SLN with both techniques. In 3 patients the

detection of SLN with ferromagnetic particles was not possible (1 patient had previous surgery). In 13 cases both techniques located the same SLN (44.8%). When the injection site was the same, the correlation observed for both techniques was 63.6%; when radioactive tracer was injected intra / peritumoral this concordance droped to 33.3%. SentiMag® was faster in the location of SLN in 9 patients, in 6 patients a greater number of SLN were detected. In 13 patients the conventional gamma probe detected SLN more easily and in 3 patients was the only technique that located the SLN. The mean operating time was 44 min with SentiMag® vs 38 min with the radiotracer. Conclusions: SentiMag® detects a discrete higher number of SLN. When the injection site differs there is a major discrepancy in SLN detection between techniques. In some cases the SLN has been detected only with the conventional technique.

Gastrin-releasing peptide receptor expression is associated with estrogen receptor status in breast cancer: Findings of a PET/CT pilot study

C. Stoykow[1,2,3], T. Erbes[4], S. Bulla[1], H. Mäcke[1], V. Drendel[5], P. Bronsert[5,6], M. Werner[5,6], E. Stickeler[4], P. T. Meyer[1]; [1]University Medical Centre Freiburg, Department of Nuclear Medicine, Freiburg, GERMANY, [2]German Cancer Consortium (DKTK), Freiburg, GERMANY, [3]German Cancer Research Center (DKFZ), Heidelberg, GERMANY, [4]University Medical Centre Freiburg, Department of Gynecology and Obstetrics, Freiburg, GERMANY, [5]University Medical Centre Freiburg, Department of Clinical Pathology, Freiburg, GERMANY, [6]German Cancer Consortium (DKTK), Heidelberg, GERMANY.

The gastrin-releasing peptide receptor (GRPR) is overexpressed in several human tumors. The purpose of the present study was to evaluate GRPR imaging as a novel diagnostic approach in breast cancer. We employed positron emission tomography (PET) and the novel GRPR antagonist [68Ga]RM2, which has been developed by our group. [68Ga]RM2 possesses a low nanomolar affinity for GRPR and has already been successfully studied in prostate cancer. Fourteen female patients with histologically confirmed, locally advanced primary breast carcinoma (3 bilateral tumors) underwent PET/CT for pretreatment staging on compassionate-use basis. PET/CT was acquired 1h after injecting 150-200MBq [68Ga]RM2. In vivo GRPR binding was correlated with estrogen (ER) and progesterone (PR) expression, HER2/neu status and MiB-1 proliferation index of biopsy specimens. Normal breast tissue showed an inter-individually variable, moderate heterogeneous GRPR binding (SUVMAX 2.27±1.02), while physiological uptake of most other tissues/organs was considerably less (SUVMEAN liver, muscle and fat: 1.10±0.32, 0.38±0.10 and 0.19±0.04) except pancreas (52.7±11.6). 12/17 tumors were clearly visualized by strongly increased uptake compared to normal breast tissue (PET-positive). Noteworthy additional findings included the detection of small internal mammary lymph nodes (2-3mm) with strong GRPR binding, a contralateral axillary lymph node metastasis (n=1; verified by biopsy) and bone metastases not detected by other imaging modalities (n=1). All PET-positive tumors were ER- and PR-positive, in contrast to only 1/5 PET-negative tumors (Fisher's exact test $p=0.002$; SUVMAX 10.80 ±6.21 and 2.31±0.97 in ER-positive and ER-negative tumors, respectively). In a multivariate analysis including ER, PR, HER2/neu and MiB-1, only ER expression predicted GRPR binding ($R2=0.56$, $p<0.05$). This pilot study demonstrates that GRPR PET/CT is a promising diagnostic modality in ER-positive breast cancer. GRPR imaging may serve as a possible surrogate marker for ER expression with putative therapeutic and prognostic importance.

PW083

Measurement of early treatment response in patients with recurrent or metastatic breast cancer with 18F-FLT and 18F-FDG PET/CT: a pilot study

T. Su, S. Chan, K. Lui, J. Huang; Chang-Gung Memorial Hospital Keelung Branch, Keelung, TAIWAN.

Aim: 18F-FLT and 18F-FDG PET have been proved useful in monitoring treatment response of recurrent or metastatic carcinoma. However, combination of 18F-FLT and 18F-FDG PET in assessing treatment outcome of recurrent/metastatic breast cancer has not been reported. In this prospective study, we investigated the imaging biomarkers, 18F-FLT and 18F-FDG, to measure early treatment response in recurrent/metastatic breast cancer after the first and second cycles of taxane- or cisplatin-based chemotherapy. Materials and methods: Eleven patients with recurrent or metastatic breast cancer, who were about to commence a new pharmacological treatment regimen, were recruited. Each individual underwent 18F-FLT and 18F-FDG PET/CT at baseline, and after the first and second cycles of the new regimen. Treatment response was based on the results of 3-month post-therapy conventional work-up, with criteria of the Response Evaluation Criteria in Solid Tumors (RECIST) 1.1. Variables from 18F-FLT and 18F-FDG PET scans were correlated with the conventional imaging results. Results: Treatment response determined by RECIST 1.1 showed 5 responders and 6 non-responders. In all responders, systemic treatment had resulted in decreases in both 18F-FDG and 18F-FLT uptake

(SUVmax): -15.0±8.0% and -24.5±28.7% after one cycle; -50.6±26.0% and -37.8±39.7% after two cycles. Among non-responders, however, 5 subjects (5/6, 83%) also had decreased 18F-FDG uptake, and the changes of SUVmax were -12.3±14.4% and -24.0±14.2% after the first and second course of chemotherapy. In contrast, the corresponding 18F-FLT SUVmax uptake in non-responders showed increased tendencies compared to the baseline images (0.0±28.6% and 16.3±61.6%). In subjects with pure bony metastases (2/11), the 18F-FDG-avid bone lesions which showed no 18F-FLT uptake ended in good response to treatment, and the 18F-FDG PET could not correctly predict the good response. Conclusion: Tumor uptake assessed by 18F-FLT PET early after initiating systemic therapy appears to be a superior marker than 18F-FDG PET to predict treatment response in patients with recurrent/metastatic breast cancer. For solely bony metastasis group, presentation of 18F-FLT-photopenic lesions may be a good prognosticator.

PW084

Sentinel-node in cervical cancer patients: preoperative assessment with SPET/CT and comparison with intra-operative gamma-probe and methylene blue-dye

M. Cuzzocrea[1], F. Elisei[2], C. Crivellaro[1], C. Dolci[1], A. Buda[3], M. Signorelli[3], L. Guerra[2], D. Giuliani[4], M. Arosio[2], R. Milani[5], C. Landoni[5]; [1]University of Milan-Bicocca, Nuclear Medicine, Milan, ITALY, [2]Nuclear Medicine Department, San Gerardo Hospital, Monza, ITALY, [3]Gynaecology Department, San Gerardo Hospital, Monza, ITALY, [4]University of Milan-Bicocca, Gynaecology, Milan, ITALY, [5]University of Milan-Bicocca, Milan, ITALY.

BACKGROUND AND AIM OF THE STUDY: Lymph-node status is a major prognostic factor in cervical cancer (CC). Sentinel lymph-node (SLN) biopsy has been reported in CC, even if not yet a standard-of-care procedure. Aim of this study was to compare preoperative SPET/CT with gamma-probe and methylene blue-dye (MBD) in identification of SLN in early-stage CC. METHODS: 25 clinically early-stage CC women (66.7±9.7years, stage I-IB2) underwent preoperative lymphoscintigraphy. Tc-99m albumin nanocolloid was injected submucosally at 4 points of the cervix. After about 3 hours all patients underwent SPECT/CT study. MBD was injected into the cervix just before surgery under general anesthesia. All patients underwent hysterectomy, bilateral salpingo-oophorectomy, and radical pelvic nodal dissection. SPET/CT findings were compared to gamma-probe and MBD techniques. RESULTS: The detection rate of at least one SLN resulted 100% (25/25 patients) with SPET/CT, 92% (23/25) intra-operatively with gamma-probe and 84% (21/25) with MBD. Only in 18/25 (72%) patients a bilateral migration was obtained with all considered modalities. In particular, bilateral detection was achieved in 16 patients with SPET/CT (64%), in 11 patients with gamma-probe (44%) and in 8 patients with MBD (32%). The concordance site between SPET/CT and intra-operatively gamma probe resulted 80% (in 20/25 patients: 9 bilateral and 11 monolateral SNs); while concordance site with MBD was found in 32% (21/25 patients: 6 bilateral, 15 monolateral SNs). In the only 2/25 cases with failed SN detection by gamma probe, SPET/CT had revealed nodal uptake, however the intra-operative SN recognition was obtained with MBD. Overall 677 LNs were dissected (mean 27 LNs per patient), among which 74 SLNs (mean 3 SLNs per patient). Of 74 SLNs: 34 were "hot and blue (HB)", 15 blue only and 25 hot only. Eleven/74 SNs resulted positive for metastases in 5 patients (5 HB, 3 hot only and 3 blue only), with an incidence of LN metastases of 20%. Five positive non-SLNs were found in 2 patients, all with concomitant metastatic SLNs. False negative rate was 0%. CONCLUSIONS: Detection rate of at least one SLN was 100% with SPET/CT, 92% intra-operatively with gamma-probe and 84% with MBD. SPET/CT achieved the highest rate of optimal node mapping (bilateral migration 64%). Of 74 dissected SLNs, 34% were recognized by isotopic technique only, 20% by MBD only and 46% by both, confirming the complementary role of dual technique.

PW085

Comparison of imaging modalities (CT, FDG-PET/CT) in head and neck cancer patients

Z. Besenyi[1], S. Urbán[2], K. Hideghethy[3], T. Séra[1], Z. Lengyel[4], L. Pávics[1]; [1]University of Szeged Department of Nuclear Medicine, Szeged, HUNGARY, [2]University of Szeged,Institute of Informatics, Szeged, HUNGARY, [3]University of Szeged Department of Oncology, Szeged, HUNGARY, [4]Positron Diagnostics Ltd, Budapest, HUNGARY.

Introduction: The aim of this study was to evaluate the role of FDG-PET/CT in head and neck cancer patient treatment strategy. Gross tumor volumes delineation methods based on positron emission tomography and conventional topoCT were compared. The impact of tumor volumes were evaluated in overall and disease specific survival. Methods: 70 oncologic patients with primary head-neck cancer were enrolled in the current study. Within 3 weeks difference CT and FDG-PET/CT image acquisition were completed separately in planned irradiation position. Gross tumor volume were determined by manually contouring independently both on conventional CT based topometric slices and FDG-PET/CT images.

Radiotherapy target volume was calculated (GTV-pet GTV-ct [cm3]) using both modalities and numerical and geometrical comparisons were assesed. For a geometrical comparison manually contoured tumor shapes intersection divided by union ratio was calculated. This I/U ratio is a value between 0 and 1, where a value of 1 means full overlap and value of 0 means no overlap. Results: In regards to the total population radiotherapy target volume as assessed by FDG-PET/CT differed in 98 % (69/70) from target volumes calculated by topoCT. According to metabolic information the planned irradiation field was greater in 10 cases (14 %) and smaller in 59 cases (84 %). Significant differences were seen between CT and PET/CT based tumor volume (paired t-test $p<0.0001$). In point of geometrical view the calculated I/U ratio was average 0.37 ± 0.20 SD. Maximum value: 0.8, minimum: 0.014. The geometrical comparison showed large variation and the average ratio shows weak overlap. After average 6.4 years follow up the overall and disease specific survival showed close correlation with GTV-pet ($p=0.0001$). Conclusion: The CT and FDG-PET/CT based tumor target volumes differed significantly from each other. Differences between two modalities were even more apparent when not only tumor volume but geometric dimensions were also calculated. Our results showed that CT based morphologic information overestimates the tumor volume in larger lesions and can underestimate it in smaller target lesions in head and neck cancer. Radiotherapy planning based on the combination of structural and metabolic information with implementation of modern radiotherapy techniques may improve the efficacy of cancer therapy.

PW086

Clinical Value of FAZA-PET/CT in Head and Neck Cancer Patients

T. Saga[1], M. Inubushi[2], M. Koizumi[3], K. Yoshikawa[1], M. Zhang[1], T. Obata[1], R. Harada[4], T. Uno[4]; [1]National Institute of Radiological Sciences, Chiba, JAPAN, [2]Kawasaki Medical School, Kurashiki, JAPAN, [3]Cancer Institute Hospital, Tokyo, JAPAN, [4]Chiba University Graduate School of Medicine, Chiba, JAPAN.

Aim: The presence of hypoxia in cancer tissue is known to increase not only their refractoriness to treatment, but also their malignant potential. The information of cancer hypoxia, therefore, is important for the management of cancer patients such as prediction of treatment response and the selection of appropriate treatment strategy. The aim of the present study was to evaluate the clinical value of PET/CT with FAZA, a PET probe to detect cancer hypoxia, in head and neck cancer patients, especially on the prediction of patients' prognosis. Materials and Methods: Twenty-nine patients with head and neck cancer (stage I: 1 patient, stage II: 2 patients, stage III: 8 patients, stage IV: 18 patients; squamous cell carcinoma (SCC): 26 patients, non-SCC: 3 patients) received FAZA-PET/CT before treatment. Patients were followed to determine the treatment response and survival. Uptake parameters of FAZA (tumor-muscle ratio at 2 hours post-injection (T/M)) in primary lesion and lymph node metastasis were compared with various clinical parameters. Progression-free survival (PFS) was compared with clinical and FAZA uptake parameters in SCC patients who received chemoradiation therapy (CRT). Study protocol was approved by the institutional review board, and informed consent was obtained from all patients. Results: Among SCC cases, there was a significant correlation between FAZA primary T/M and maximal diameter of primary lesion ($P = 0.007$, $r = 0.517$). FAZA primary T/M was significantly higher in stage IV patients than in stage I ~ III patients ($P = 0.003$), and was significantly higher in T2 ~ 4 patients than in T1 patients ($P = 0.009$). Although not statistically significant, SCC patients who developed disease progression after CRT tended to show higher FAZA primary T/M than those who did not develop disease progression (1.70 ± 0.30 vs. 1.48 ± 0.36, $P = 0.095$). Kaplan-Meier analysis with Log-Rank test has shown that, among various clinical and PET parameters, only FAZA primary T/M was a significant predictor of PFS ($P = 0.010$), in which patients with FAZA primary T/M > 1.565 showed significantly worse PFS rate than those with FAZA primary T/M ≤ 1.565. Conclusion: FAZA primary T/M was a significant predictor of PFS in head and neck SCC patients receiving CRT. Pretreatment FAZA-PET/CT can afford useful information on the management of head and neck cancer patients.

PW087

Diagnostic accuracy of 18F-FDG PET/CT in primary staging of cutaneous malignant melanoma according to Breslow thickness: a preliminary study

S. Diodato[1], S. De Vivo[1], C. Baraldi[2], G. Veronesi[2], E. Dika[2], S. Fanti[2,1], A. Patrizi[2], S. Vaccari[2]; [1]Nuclear Medicine, Policlinico S.Orsola-Malpighi, University of Bologna, Bologna, ITALY, [2]Dermatology Unit, Policlinico S.Orsola-Malpighi, University of Bologna, Bologna, ITALY.

Aim: The purpose of this study was to assess sensitivity and specificity of 18F-FDG PET/CT to detect lymph node and soft tissue/visceral metastasis in the primary staging of cutaneous malignant melanoma (CMM). Materials and methods: We retrospectively evaluated 76 patients, 52 male and 24 female, mean age 62 y.o. (range 28-93), with a histological diagnosis of CMM, who underwent initial staging 18F-FDG PET/CT between april 2004 and november 2011 at Nuclear Medicine Unit, University of Bologna. Histological features of the primary tumors were available for all patients. Patients were

classified into 3 groups: group A (Breslow thickness <0,75 mm, 11 pts), group B (Breslow thickness 0,76-1,5 mm, 15 pts) and group C (Breslow thickness >1,5 mm, 50 pts). The results of the PET/CT scans were compared with those obtained by further histopathologic evaluations and/or clinical and radiological investigations, up to 3-6 months. Results: Overall sensitivity and specificity were respectively 61,5% and 93,5%. In group A and B sensitivity was 100% both for N- and M-staging. Specificity in group A was 100% for detection of lymph node metastasis and 90% for distant metastasis: the unique false positivity was observed in a patient presenting a cutaneous/subcutaneous moderately hypermetabolic lesion, that resulted a sebaceous cyst at histological examination. Specificity in group B was 100% for M-staging and 93% for N-staging. In group C sensitivity was 55,5% for N-staging and 66,7% for M-staging: a false negative result was observed in a patient with a pulmonary nodule without increased FGD uptake, that further resulted as a metastasis from CMM in the radiological follow up. Specificity was 100% for distant metastasis and 94,9% for lymph node metastasis. Diagnostic accuracy in group A, B and C were respectively 91%, 93% and 84%. Conclusion: Sensitivity and specificity of 18F-FDG PET/CT in N- and M-staging of CMM seem to be higher in patients with Breslow thickness <1,5 mm. These results are quite in contrast with the trend of studies in literature that reported a better diagnostic performance of PET/CT in high risk patients with CMM. Further studies including a larger number of patients with lower Breslow thickness are necessary to assess the potential role of PET/CT in primary staging based on Breslow's depth. Other prognostic factors , such as the number of mitoses and the presence or absence of ulceration on the histopathologic evaluation of the primary melanoma should be evaluated together with Breslow thickness.

PW088

Comparison of ^{123}I-IMP SPECT, ^{18}F-FDG PET, and ^{18}F-FDOPA PET in Detection of Uveal Malignant Melanoma

K. Kato[1], S. Tsuchiya[1], Y. Koshiba[1], T. Odagawa[1], S. Abe[2], T. Kubota[3], H. Terasaki[1], S. Naganawa[1]; [1]Nagoya University Graduate School of Medicine, Nagoya, JAPAN, [2]Nagoya University Hospital, Nagoya, JAPAN, [3]Nagoya Medical Center, National Hospital Organization, Nagoya, JAPAN.

Aim: Previously we showed that ^{123}I-IMP SPECT is a sensitive and accurate method for the detection of uveal malignant melanoma. The feasibility and usefulness of ^{18}F-FDOPA PET for detection of uveal malignant melanoma have not yet been established. The purpose of this study is to compare the usefulness of ^{123}I-IMP SPECT, ^{18}F-FDG PET, and ^{18}F-FDOPA PET for detection of uveal malignant melanoma. Materials and Methods: Forty-six patients with suspected uveal malignant melanoma were examined by ^{123}I-IMP SPECT, ^{18}F-FDG-PET/CT, and ^{18}F-FDOPA PET/CT. Results: In 29 of 46 study patients, ^{123}I-IMP SPECT showed markedly increased uptake in the site corresponding to the ocular tumor. In 26 of the 29 patients showing increased uptake of ^{123}I-IMP, the ocular tumors were confirmed histopathologically or clinically to be uveal malignant melanoma. The ocular tumors in the other 3 patients showing increased uptake of ^{123}I-IMP was diagnosed as small choroidal melanocytic lesions. The 17 ^{123}I-IMP SPECT-negative cases comprised 7 small melanocytic lesions, 1 choroidal hemangioma, 1 adenoma, and 2 melanocytoma, 2 metastases, 3 hemorrhages, and 1 unknown benign lesion. Nineteen of 20 of uveal malignant melanoma showed positive uptakes in ^{18}F-FDG PET and ^{18}F-FDOPA PET. The uptakes of both ^{18}F-FDG and ^{18}F-FDOPA were much weaker than that of ^{123}I-IMP. The range and mean ± SD of SUVmax for ^{18}F-FDG and ^{18}F-FDOPA in uveal malignant melanoma were 1.70-10.35, 3.78 ± 0.88 and 0.74-4.63, 1.18 ± 0.06, respectively. The difference between the uptakes of both tracers was statistically significant. Thus the uptake of ^{18}F-FDOPA was weaker than that of ^{18}F-FDG. Conclusion: ^{123}I-IMP SPECT is superior to ^{18}F-FDG and ^{18}F-FDOPA PET for the detection of uveal malignant melanoma. Efficacy of ^{18}F-FDOPA PET is for the detection of uveal malignant melanoma is low compared with ^{18}F-FDG PET because of its weak uptake into uveal malignant melanoma.

PW089

Potential impact of 18F-Fluorothymidine PET/CT in lymphoma patients with suspect residual disease or relapse.

L. Zanoni[1], A. Broccoli[2], C. Nanni[1], C. Pellegrini[2], F. Lodi[1], C. Fonti[1], P. Ghedini[1], S. Cambioli[1], P. Zinzani[2], S. Fanti[1]; [1]Nuclear Medicine, University Hospital S'Orsola-Malpighi, Bologna, ITALY, [2]Hematology "L. e A. Seràgnoli", University Hospital S'Orsola-Malpighi, Bologna, ITALY.

AIM: To evaluate the role of 18F-fuorothymidine (FLT) PET/CT in patients (pts) affected by lymphoma, presenting with positive or inconclusive 18F-deoxyglucose (FDG) PET/CT at end-treatment or follow-up. MATERIALS AND METHODS: Mono-centric prospective study. From May 2010 to March 2015, overall 40 pts were enrolled. They all underwent FLT PET/CT within 3 weeks from a previous positive or inconclusive FDG scan at end-treatment or follow-up and, when possible, biopsy confirmation as standard of reference to define PET results (true positive-TP; true negative-TN; false positive-FP; false negative-FN). The highest lesion SUVmax was measured with both tracers. RESULTS: Pts characteristics: mean age 55 (range 20-76); 24

males and 16 females; 30 non-Hodgkin (NHL) and 10 Hodgkin lymphoma (HL); stage at diagnosis: 8 II, 8 III, 24 IV; 6 pts were evaluated at end-treatment and 34 during follow-up/restaging. FDG-PET were judged positive in 36 out of 40 cases (mean SUVmax=10.1; range 3-31). 8/36 scans resulted also FLT positive (mean SUVmax= 7.8; range 3-16.8): 16/28 pts had the most active lesion biopsied, demonstrating 15 TP but 1 FP (HL patient presenting with FDG-SUVmax 6.9 and FLT 6.8 in cervical node: reactive follicular hyperplasia) whereas the remaining 12/28 pts could not be biopsied for ethical/practical reasons but subsequent follow-up data and final clinical evaluation (CE) confirmed 11 TP and 1 FP(reactive cervical node). 8/36 scans resulted FLT inconclusive in the light of lesion distribution and relatively lower SUVmax values (mean 4.8; range: 1.7-11.7): 5/8 were defined as TP at biopsy (2) or CE (3), whereas 3/8 represented inflammatory tissue (1 histologically-proven sarcoidosis-like reaction in mediastinal and supraclavicular nodes; 2 reactive axillary-mediastinal nodes and supraclavicular lymphadenopathy, respectively, at CE). The remaining 4/36 FDG-PET were considered inconclusive (mean SUVmax=7.2; range 4.9-8.8). 3 out of 4 were also defined inconclusive at FLT (mean SUVmax=4; range 2.6-4.9), but the final CE excluded lymphoma (1 reactive cervical node, 1 supra-diaphragmatic nodal sarcoid-like disease, 1 aspecific pericecal finding). The remaining 1/4 resulted FLT positive (SUVmax 6.9 and 6.5 for FDG and FLT, respectively) and was confirmed TP at CE. CONCLUSION: In the particular setting of residual/recurrent lymphoma, our preliminary data suggest that FLT might be complementary although not alternative to FDG. The elimination of inconclusive PET findings still represents a controversial step, therefore biopsy confirmation remains mandatory. Further lesion/semi-quantitative (i.e. target to background/mediastinal blood pool/liver ratio)/Ki67 correlation analyses are ongoing.

PW090

Comparison of 18F-FDG PET/CT and PET/MRI for the assessment of multiple myeloma

C. Sachpekidis[1], J. Hillengass[2], H. Goldschmidt[2], J. Mosebach[3], H. Schlemmer[3], U. Haberkorn[4], A. Dimitrakopoulou-Strauss[1]; [1]Clinical Cooperation Unit Nuclear Medicine, German Cancer Research Center, Heidelberg, GERMANY, [2]Medical Clinic V, University of Heidelberg, Heidelberg, GERMANY, [3]Department of Radiology, German Cancer Research Center, Heidelberg, GERMANY, [4]4Division of Nuclear Medicine, University Clinic Heidelberg, Heidelberg, GERMANY.

Objective: The aims of this prospective study are to evaluate the feasibility of 18F-FDG PET/MRI in detection of myeloma, and to investigate the reproducibility of bone marrow lesions detection and quantitative data of 18F-FDG uptake between the functional (PET) component of PET/CT and PET/MRI in MM patients. Patients and methods: The study includes 29 patients diagnosed with MM according to the International Myeloma Working Group criteria. All patients initially underwent 18F-FDG PET/CT (60 min after tracer injection), followed by PET/MRI (120 min after tracer injection). PET/CT and PET/MRI data were assessed and compared based on qualitative (lesion detection) and quantitative (SUV) evaluation. Results: The hybrid PET/MRI system provided good image quality in all cases without artefacts. PET/MRI identified 59 of the 63 lesions, which were detectable with PET/CT (93.7%). Three focal rib lesions and one lesion in os ilium in three patients were missed by PET/MRI. Quantitative PET evaluations showed the following mean values in MM lesions: SUVaverage=5.6 (median 5.1) and SUVmax=8.1 (median 7.1) for PET/CT; SUVaverage=4.1 (median 3.9) and SUVmax=6.0 (median 5.7) for PET/MRI. According to Wilcoxon matched-pairs signed rank test, both SUVaverage ($p<0.0001$) and SUVmax ($p<0.0001$) derived from MM lesions were significantly higher on PET/CT than on PET/MRI. Spearman correlation analysis demonstrated a strong correlation between both lesional SUVaverage ($r=0.755$, $p<0.0001$) and lesional SUVmax ($r=0.864$, $p<0.0001$) values derived from PET/CT and PET/MRI. Conclusion: Our study demonstrated that the PET/MRI hybrid system provides good image quality in MM and detected 93.7% of the PET/CT lesions. In terms of tracer uptake quantitation, a strong correlation between the two techniques was demonstrated, despite the statistically significant differences in lesional SUVs between PET/CT and PET/MRI.

PW091

The thyroid stunning effect: according to Poisson statistics, a small fraction of an ablative dose already kills a large fraction of cells.

S. Walrand, M. Hesse, F. Jamar; Université Catholique de Louvain, Brussels, BELGIUM.

Aim: The origin of the reduction in thyroid uptake after a low activity iodine scan, so-called stunning effect, is still controversial. Two explanations prevail: an individual cell stunning that reduces its capability to store iodine without altering its viability or a significant cell killing fraction that reduces the number of cells in the tissue still taking up iodine. Our aim is to analyze whether this last assumption could quantitatively explain the observed reduction. Methods: tumor (or tissue) control probability (TCP) is governed by Poisson statistics (Brahme and Agren 1987), i.e: TCP(A) = exp (-Nc x Sf(D(A))) = exp(-Nc x exp(-α D(A))) (1) where Nc is here the number of cells alive before ablation (about $4x10^7$ for 1 g of remnant tissue), Sf the survival fraction, α the cells radiosensitivity and D the mean delivered dose which is nearly proportional to the administrated activity A. Recent studies showed that a single administration of 30 mCi of I131 provides a TCP of about 75% and that a diagnostic dose of 2 mCi of I131 can induce in a following administration an uptake reduction ranging from 20 to 90%. Results: straight inversion of eq. 1 gives: Sf(A) = exp(-α D(A)) = -ln(TCP(A)) / Nc (2) Using TCP(30mCi) ≈0.75 and eq. 2, we get for 1 g of tissue: Sf(30mCi) ≈ $7x10^{-9}$ and Nc x Sf ≈ 0.3. However even if Nc x Sf < 1, due to the random nature of radiation killing, in 25% of 30 mCi-treatments there remain enough surviving cells to allow remnants relapsing. As D(2 mCi) ≈ D(30 mCi)/15, one has Sf(2 mCi) ≈ exp(-a D(30mCi)/15) = $(Sf(30mCi))^{1/15}$ ≈ 29% which is sufficient to induce a uptake reduction of 70% in a scan following a 2 mCi-diagnostic scan. Furthermore, this statistical demonstration, showing that a small fraction (1/15) of an ablative dose already kills a significant fraction of cells (≈70%), was experimentally proved in mega-colony cell assay (Kappler et al. 2007). Conclusion: The statistical analysis shows that the uptake reduction effect can be purely explained by the cell killing fraction. This supports the non-existence of an individual cell stunning effect that, if present, should induce an additional uptake reduction resulting in much larger decreases than those observed. As the β/α ratio measured in thyroid cancer cell assay is very low, this effective fractionation of the therapy should not impact the patient outcome in agreement with recent studies.

PW092

Thyroid remnant ablation in differentiated thyroid cancer: searching for the most effective radioiodine activity and stimulation strategy ina real life scenario

A. Campenni'[1], L. Giovanella[2], S. Pignata[1], M. Murè[1], M. Siracusa[1], F. Cosentino[1], L. Sturiale[1], P. Coppolino[1], M. Ruggeri[3], S. Baldari[1]; [1]Nuclear Medicine Unit of Messina, Messina, ITALY, [2]Nuclear Medicine and PET/CT centre, Oncology Institute of Southern Switzerland, Bellinzona, Switzerland., Bellinzona, SWITZERLAND, [3]Department of Clinical and Experimental Medicine and Pharmacology, Section of Endocrinology, University of Messina, Messina, Italy, Messina, ITALY.

AIM: Differentiated thyroid cancer (DTC) is rare but incidence has been increasing in the last few decades. Early treatment is based on surgery and thyroid remnant ablation (TRA) by radioiodine therapy. Despite radioiodine being widely used for decades, the choice of ablative activity is generally empirical and no consensus has been reached to date. The aim of our study was to compare the efficacy and safety of different radioiodine activities. In addition, we compared the ablation rate in patients treated in hypothyroid state or after recombinant human TSH (rhTSH) administration.MATHERIAL AND METHODS: We reviewed, retrospectively, the records of 471 patients (376 Female, 95 Male; F:M 3.9:1; mean age 46.5±10.8 years, ranges 16-74) affected by DTC and admitted to our University Hospital. Among 471 patients, 394 (83.6%) were papillary histotype (PTC), 77 (16.4%) were follicular histotype (FTC); 84 (17.8%) were pT1N0M0, 232 (49.2%) were pT2N0M0, 155 (32.9%) were pT3N0M0. Inclusion criteria were: age > 16 years, no loco-regional or distant metastases, not pregnant. All patients underwent radioiodine therapy (RAIT) after total or near-total thyroidectomy. Fifty-seven per cent of patients underwent RAIT after thyroid hormone withdrawal to achieve a serum thyrotropin (TSH) level above 30 μUI/ml. The remaining patients were treated after rhTSH-stimulation (0.9 mg daily for two consecutive days administered by intra-muscular injections). The patients were divided into three groups according to different radioiodine activity administered (A: 1110 MBq, B: 2220 MBq, C: 3700 MBq). Such activities were established by the attending physician on the basis of age, sex, TNM staging, histological variant, coexisting Hashimoto thyroiditis. All patients underwent neck-ultrasonography before RAIT, and those treated in hypothyroid state also at radioiodine uptake, obtained 24 hours after administration of radioiodine tracer activity (1.8 MBq). RESULTS: The success of TRA was evaluated twelve months later. TRA was obtained in: 62/79 (78.5%) in Group A (1110 MBq in hypothyroid state), 183/190 (96.3%) in Group B [2220 MBq in hypothyroid state or after rhTSH-administration: 87/90 (97%) and 96/100 (96%), patients respectively], 199/202 (98.5%) in Group C [3700 MBq in hypothyroid state or after rhTSH-administration:

98/100 (98%) and 101/102 (99%), patients respectively].CONCLUSIONS: Our data demonstrate that 2220 and 3700 MBq radioiodine are more effective than 1110 MBq in TRA, without significant differences between 2220 and 3700 MBq or between hypothyroidism and euthyroidism. We suggest rhTSH-aided TRA with 2220 MBq 131-radioiodine as this approach permits efficacious treatment reducing side effects, absorbed dose to body and hospital stay.

PW093

Selenium as a radiation protector of salivary glands in radioiodine remnant ablation therapy

M. Marx, S. Fastenmeier, M. Zuhayra, U. Lützen; Universitätsklinikum Schleswig-Holstein, KIEL, GERMANY.

Aim: Salivary gland impairment following high-dose radioiodine treatment is well known. This study investigates the effect of selenium to salivary glands of patients with well differentiated thyroid carcinoma receiving a radioiodine remnant ablation therapy (RAA). Furthermore the influence to remnant ablation was examined. Methods: 13 patients (group A) aged 26 - 75 years (mean 50,2 years) received 1000 µg selenium 30 minutes prior to application of 3,0 to 6,0 GBq I-131 (mean 3,4 GBq). A matched controll group (group B) aged 22 - 81 years (mean 50,9 years), received 3,0 to 6,0 GBq (mean 3,3 GBq) without selenium. The salivary gland function was investigated by salivary gland scintigraphy with Tc-99m-Pertechnetat prior to therapy and 3 months after RAA. The selenium concentration in serum was measured prior to and 72 h after therapy, also thyroglobulin (TG) before therapy as well as 3 and 6 months after therapy. Six months after RAA a radioiodine whole body scan (WBS) with I-131 was performed. Results: The patients in group A showed an average selenium concentration in serum of 75,15 mg/dl (57,0-92,0) at baseline with an significant increase to 102,0 mg/dl (73-134) 72 h after administration of selenium (p=0,00015). Prior to therapy in group A an uptake of Tc-99m in salivary glands (SG) of 0,20%±0,11% (0,10%-0,41%) was measured compared with 0,19%±0,08% (0,07%-0,33%) three months after therapy. In group B SG-uptake was determined 0,15%±0,06% (0,04%-0,24%) prior to and 0,08%±0,03% (0,05%-0,17%) after therapy. There was no significant change of salivary function in group A (p=0,85) but in the control group B (p=0, 0016). The success of ablation therapy (no measurable TG, no remnant tissue in WBS) was not affected by selenium administration. Conclusions: This first results indicate that damage to salivary glands induced by radioiodine therapy can be reduced significantly by selenium. A placebo controlled study with a greater number of patients is necessary and in planning.

PW094

Association between iodine intake and treatment outcomes of radioiodine remnant ablation in patients with intermediate risk papillary thyroid cancer

Y. Sun, W. Ouyang; Department of Nuclear Medicine, Zhujiang Hospital,Southern Medical University, Guangzhou, CHINA.

Aim To evaluate the association between iodine intake and treatment outcomes of radioiodine remnant ablation in American Thyroid Association (ATA)-intermediate papillary risk thyroid cancer(PTC) patients, and to investigate the determinants related to the ablation efficacy. Materials and Methods A total of 95 ATA-intermediate PTC patients were enrolled into the retrospective study. All patients had undergone total thyroidectomy and 2-4 weeks of low iodine diet (LID) before initial 131I therapy. According to urinary iodine excretion(UIE) of patients, they were divided into 3 groups: moderate-severe iodine deficient(UIE<50 ug/L, n=30), mild iodine deficient(UIE 50~100ug/L, n=26), adequate iodine (UIE 100~300 ug/L, n=39). Patients were followed up for 8 to 12 months after ablation, successful ablation was defined using the definition: no visible uptake in the thyroid bed on a follow-up scan and a stimulated thyroglobulin(sTg) level <2 ng/mL. Chi-square test, t-test, Mann Whitney rank-sum test and multivariate binary logistic regression analysis were performed. Results 84.2%(80/95)of patients were successfully ablated. The successful rates in the three different iodine intake groups were 96.7%(29/30), 84.6%(22/26), 74.4%(29/39), respectively, with significant difference among three groups. Besides UIE, univariate analysis revealed that TSH, sTg, remnant thyroid at ablation affected ablation efficacy. Logistic regression showed that sTg(OR=1.120) and adequate iodine intake(OR=3.473) were independent factors of ablation efficacy. Conclusion Adequate iodine intake during 131I remnant ablation is one of important factors of treatment outcomes. Thyroid remnant is more successfully ablated if we make reasonable LID protocols according to the iodine nutritional status in ATA-intermediate PTC patients before treatment.

PW095

Prognostic significance of early thyroglobulin release after radioiodine therapy under rhTSH for thyroid cancer

M. EBERLE[1], E. GALL[2], S. GUILLEMARD[1], C. ESPITALIER[1], I. RAINGEARD[2], C. CARTIER[2], M.

JARLIER[1], H. DE FORGES[1], P. KOTZKI[1], E. DESHAYES[1]; [1]ICM Val d'Aurelle, MONTPELLIER, FRANCE, [2]CHU, MONTPELLIER, FRANCE.

Aim: The main objective of our study was to determine if serum thyroglobulin values after radioiodine ablation therapy performed with recombinant human thyrotropin (rhTSH), at 3 days (TgD3) and 6 days (TgD6) post rhTSH injection, and the ratio TgD6/ TgD3, were predictive for disease free status at 6-12 months following therapy. The secondary objective was to determine if remnant tissue uptake was correlated to these thyroglobulin values, and would influence their interpretation. Patients and Methods: We included retrospectively all consecutive patients who underwent radioiodine ablation therapy under rhTSH after surgery for thyroid cancer in our department between January 1st of 2011 and June 1st of 2013. Thyroglobulin was measured at D3 (i.e. 24h after the second rhTSH injection), just before radioiodine administration, and at D5 or D6 (48h or 72h after I131 administration). Whole-body scan was performed at the same time. Remnant tissue was estimated by measurement of thyroid bed uptake on whole-body scintigraphy performed at D5 or D6. Thyroid bed uptake values were divided into 3 strata (defined by the 33th and 66th percentiles). According to current guidelines, patients were considered disease-free at 6-12 months follow-up if neck ultrasound showed no abnormalities and stimulated thyroglobulin was below 1 ng/mL (or below 0.3 ng/mL if stimulated thyroglobulin was not available). Patients with positive thyroglobulin-antibodies were excluded. Results: 102 patients were included (22 men, 80 women), with a median age 57 [17-87]. According to European guidelines for risk assessment, risk level was very low in 18, low in 62, and high in 22 patients. At 6-12 months follow-up, 86 patients were disease-free and 16 had persistent or recurrent disease (PRD). Significantly higher TgD3 levels were observed in the PRD group (3.1 ng/ml [0.2-132] vs 0.4 ng/ml [0.2-47.5]; p=0.0026) whereas TgD6 and ratio TgD6/TgD3 were not significantly different between the two groups. Radioiodine uptake in the thyroid bed (remnant tissue) was positively and significantly correlated to TgD3, TgD6 and ratio TgD6/TgD3 ($p<0.001$). TgD3 remained predictive of PRD only in strata 1 and 2 (lowest values of uptake in thyroid bed, $p<0.0001$). TgD6 was not significantly different between the 2 groups. Higher levels of ratio TgD6/TgD3 were observed in strata 3 in disease-free group (p=0.044). Conclusion: RhTSH stimulated thyroglobulin just before radioiodine ablation is predictive for disease-free status at 6-12 months. However, high values of early thyroglobulin release should not be considered of poor prognosis in patients with high thyroid remnant uptake.

PW096

Low-dose radioiodine therapy versus reoperation in patients after non-radical thyroidectomy with differentiated thyroid cancer.

E. Vasilenko, M. Karalkina, I. Lagozhina, D. Fomin; Russian Scientific Center of Roentgenoradiology, Moscow, RUSSIAN FEDERATION.

Aim: Comparative evaluation of the effectiveness of the final thyroidectomy and low radioiodine activities (1.2 to 2.0 GBq) in patients with differentiated thyroid cancer with significant thyroid remnant after non-radical primary surgery.Materials and Methods: The study included 90 patients (85 female, 5 male) of the age group 18-75 years with a mean age of 47 years. All patients diagnosed with DTC confirmed by histological tests (63 papillary carcinoma cases and 27 follicular thyroid cancer cases were identified, stage T1-T3, N0-N1, M0). According to postoperative scintigraphy, all patients had significant thyroid remnant. They were, depending on the treatment tactics, divided into 2 groups. The main group consists of 45 patients, for which radioiodine therapy with decreased activity (in the range of 1.2 to 2.0 GBq) was performed to ablate residual thyroid tissue. Repeated surgical treatment in these cases was not held due to the severe clinical state of patients, or due to the patients' refusal from surgery. The control group included 45 patients to whom was applied traditionally complete thyroidectomy as a preparation for radioiodine therapy. Then, patients in both groups were carried out a radical radioiodine activities from 3.0 to 4.5 GBq. A year after the administration of radical radioiodine, measurements of Tg, anti-Tg antibodies together and whole-body scintigraphy were performed. The success of ablation is determined by negative whole body I 123 scan and serum thyroglobulin level less than 2 ng/mL.Results: Successful ablation (negative stimulation test) achieved after low-dose radioiodine therapy in 33 patients (73%) after the complete thyroidectomy in the case of 32 patients (71%). During the first year of observation recurrences were detected respectively in 4 and 6 cases. The number of complications in the control group after reoperation increased to 44%, mainly due to permanent hypoparathyroidism, paresis of the larynx, a tracheostomy. All complications after low-dose

radioiodine therapy were transient and do not require additional appointments.Conclusions: The use of low-dose radioiodine therapy to eliminate excess volume of functioning thyroid tissue after surgery is equally effective as re-surgical treatment and is accompanied by fewer complications.

PW098

Thyroid remnant ablation of differentiated thyroid carcinoma: a comparison of ablation success with high and low doses of radioiodine (I-131)

S. A. A. Elrasad[1], Y. Abdelhafeez[2], M. A. Husseini[1], R. A. A. Amin[1], S. Elrefaei[1]; [1]Cairo university, Cairo, EGYPT, [2]Assuit University, Assuit, EGYPT.

Aim of study: To assess efficiency of low dose I131 in thyroid remnant ablation of patients with differentiated thyroid cancer after surgical treatment. Material and Method: A randomized double-armed trial comparing low-dose and high-dose radioiodine ablation. 128 patients (age 20-75 years) with differentiated thyroid cancer, tumor stage T1 to T3, with disease confined to the thyroid or cervical lymph nodes were treated with I131 after total thyroidectomy and pathologic lymph node resection, if present. Results were available for 88 cases. 39 patients received low dose [1110MBq (30mCi)] and 49 patients received high dose [2960-3700 MBq (80-100mCi)]. Six months after the administration of radioiodine, measurements of Tg, anti-Tg antibodies together with neck ultrasound exam and I131 whole-body scan were performed. The success rate of ablation is determined by negative whole body I131 scan, negative neck ultrasonography and serum thyroglobulin level less than 2 ng/mL. Results: Successful ablation reported in 23 out of 39 cases (58.9 %) in the group receiving low-dose radioiodine [1110 MBq] versus 37 out of 49 cases (75.5 %) in the group receiving the high dose [2960-3700 MBq]. (P value= 0.098). Six months later (1 year after the ablative dose) a second follow up was performed for the cases who had successive ablation from both groups. In the low dose group it was available for 12 out of 23 patients (52%), all of them didn't show disease recurrence, versus 17 cases out of 37 from the high dose group, 16 of them didn't had recurrence (43.2%), while in one case there was a recurrent disease at the thyroid bed. Conclusion: Initial results show no significant difference in successful ablation with low and high dose of 131-iodine. This is work in progress.

PW099

Theoretical model for release of patients with benign thyroid disease based on parameters obtained from EANM Standard Operational Procedures for Pre-Therapeutic Dosimetry II.

M. Salas[1], E. Mora[2]; [1]Nuclear Medicine Department, Hospital México., San Jose, COSTA RICA, [2]Nuclear Medicine Department, Hospital San Juan de Dios., San Jose, COSTA RICA.

Aim: To establish individualized restricted period for patients with benign thyroid disease treated with ^{131}I has been a topic of great importance for Radiation Protection. This work focuses on the use of dosimetry model of two compartments (blood pool and target tissue) that propose the *EANM Dosimetry Committee Series on Standard Operational Procedures for Pre-Therapeutic Dosimetry II. Dosimetry prior to Radioiodine Therapy of Benign Thyroid Diseases*, based on the biokinetic of the thyroid gland, and jointly with the model proposed by the United States Nuclear Regulatory Commission (U.S.NRC, *NUREG – 1556 Vol. 9*, *Rev. 2*) for release of patients.Materials and methods: *Calculus of residual activity that not exceed the dose constraint*: Using the equation suggested by U.S.NRC, with the parameters of two compartment model. Rewriting this equation in term of radioactivity, the residual radioactivity (activity contained in patient that not exceed that exposure dose constrain for population groups -children, pregnant women, adults, coworker-) was calculated. This equation present some disadvantages such as, it doesn't include a correction for the attenuation of the gamma emission of the blood pool, for this reason an attenuation correction

factor for ^{131}I (extrathyroidal component) was introduced, also it considers the patient like a point source, a correction to improve the calculus considering a line source distribution was introduced. To complete the parameters of the equation, an adequate exposure dose limit constraint, occupancy factor and expected distance (patient-population group) were chosen, trying to reproduce the family and working environment of the patient.*Calculus of restriction time*: Using two compartment model, a time to radioactivity contained in patient goes from the Administer Activity (t = 0) to the residual activity (t_{res}) was calculated, this difference in time gives the Restricted Period (time necessary for the patient follow instructions)Results and conclusion: Following the described procedure, restricted periods according to the population group and socioeconomic conditions can be calculated. If we consider a set of possible values k_B=0.1429h^{-1}, k_T=0.00525h^{-1}, k_t= 0.1297h^{-1}, Thyroid-Mass=20g, Administer-Activity = 247.19MBq, Maximum-Uptake$_{Thyroid}$ =80%, Dose$_{Target}$= 250Gy, Patient-Height=1.74m, Attenuation-Factor$_{Blood-pool}$=0.62, Exposure-Rate-Constant= 5.65x10^{-5}mSv m^2 h^{-1} MBq^{-1}. For a case of children up to two years old (1mSv Dose Constraint) at 0.3m distance (holding babe) and Occupancy factor of 0.25, the restriction time is 3.92 days.This work propose a model to calculate the individualized restricted period, considering all the possible correction that have been recommend in relation to the release of patient with hyperthyroidism treated with ^{131}I

PW100

Standardisation of Dosimetry for a Multicentre trial of Selumetinib Enhanced Radioiodine Therapy for Thyroid Cancer

R. Gregory[1,2], A. Fenwick[3], J. Merrett[4,3], J. Scuffham[4], J. Gear[1,2], D. Rushforth[1,2], I. Murray[1,2], G. Flux[1,2]; [1]Royal Marsden NHS Foundation Trust, Sutton, UNITED KINGDOM, [2]Institute of Cancer Research, Sutton, UNITED KINGDOM, [3]National Physical Laboratory, Teddington, UNITED KINGDOM, [4]Royal Surrey County Hospital, Guildford, UNITED KINGDOM.

The MEK inhibitor Selumetinib can enhance the uptake of ^{131}I NaI in patients with iodine refractory thyroid cancer enabling them to benefit from further radioiodine therapy. In this multicentre trial ^{123}I imaging is to be used to identify patients with uptake, for whom dosimetry using SPECT/CT scans will aim to predict the absorbed dose to tumours from the resulting ^{131}I NaI therapy. Dosimetry during therapy will allow assessment of the absorbed doses achieved following Selumetinib.To ensure the dosimetry results from all the centres are accurate and comparable the SPECT/CT systems are to be calibrated and validated for radioiodine imaging. There are currently no definitive standards for dosimetry. Therefore the aim of this work was to optimise the calibration procedures for practical accurate quantitative imaging.Methods:Seven sites are participating in the trial with 9 SPECT/CT systems in total. Six cylinders ranging from 1 cm to 5 cm in diameter and length were imaged separately and with 3 cylinders together, positioned in a 20 cm diameter 11 cm long cylinder of inactive water. The cylinders were filled with known activity concentrations (~1MBq/ml) of ^{123}I or ^{131}I, then the calibration factor to convert count concentrations to activity concentrations was calculated for each cylinder size and arrangement. Factors to correct for the dead time in ^{131}I images of a uniformly filled 20 cm diameter cylinder, filled with activities ranging from 10 MBq to 3 GBq were also measured. Doses received to the 4 members of staff performing this measurement were also assessed.Results: The factors to convert count concentrations to activity concentrations were comparable between separate images of the cylinders and images containing multiple cylinders for both ^{123}I and ^{131}I. The Siemens Intevo and GE Optima ^{131}I dead-time correction curves were similar up to 20 kcps at 1GBq. The staff performing these measurements received acombined whole body dose of 120 μSv.Conclusions: Calibration factors can be acquired from images of multiple cylinders so accurate calibration can be faster and more practical. Results from these measurements should help to establish good practice in planning and verifying molecular radiotherapy absorbed doses.

NTCP calculations for Selective Internal RadioTherapy (SIRT) - demonstration of the methodology

E. M. Abbott[1], A. J. Craig[2], J. M. Franklin[3], A. Denis-Bacelar[2], N. Syed[3], G. Flux[2], R. Sharma[1], K. A. Vallis[1], **N. Falzone**[1,4]; [1]MRC/CRUK Gray Institute for Radiation Oncology and Biology, Department of Oncology, University of Oxford, Oxford, UNITED KINGDOM, [2]Physics Department, Royal Marsden NHSFT, Sutton, UNITED KINGDOM, [3]Nuclear Medicine, Churchill Hospital, Oxford University Hospitals NHS Trust, Oxford, UNITED KINGDOM, [4]Tshwane University of Technology, Department of Biomedical Science, Pretoria, SOUTH AFRICA.

Aim: The aim of this study is to propose a method for applying radiobiologic models for the calculation of Tumour Control Probability (TCP) and Normal Tissue Complication Probability (NTCP), based on dosimetric and clinical data from a retrospective study. This is done to adequately interpret the local response and liver toxicity of ^{90}Y-microsphere treatment of liver metastases from colorectal cancer (CRC), hepatocellular carcinoma (HCC) and intrahepatic cholangiocarcinoma (ICC). Methods: 3-D activity distributions obtained from SPECT/CT images are combined with Monte Carlo dose voxel kernel calculations using an in-house dosimetry software package (Qrius™). Absorbed dose distribution maps (differential dose volume histograms - DDVHs) and the mean dose to healthy liver and tumour in each patient is determined using Qrius™. The Biologically Effective Dose (BED) distribution is calculated and the Equivalent Uniform Biologically Effective Dose (EUBED) is obtained from the spatial BED distribution in the volume of interest. TCP and NTCP are then calculated from the EUBED estimates. Results: Using a retrospective ^{90}Y-microsphere SPECT/CT scan, we demonstrate how a differential dose volume histogram (DDVH) generated with the Qrius™ software tool is reduced to a single dose (EUDBED) delivered to the entire volume. This functionality provides the possibility to calculate TCP and NTCP distributions. Conclusion: DVH metrics are known to correlate with patient toxicity outcomes. Adding the functionality of a convenient computational module to the Qrius™ toolkit for estimation of TCP and NTCP based on patient-specific dosimetry could facilitate patient-specific treatment planning, thus improving ^{90}Y-microsphere treatment of liver metastases.

PW102

Radiobiological Studies of Cancer Cell Using Novel External Alpha-Particle Irradiation Set-up.

J. Nilsson[1], J. Nilsson[2], M. Posaric Bauden[3], S. Strand[3], **J. H. Elgqvist**[3]; [1]Institute for Clinical Sciences, Gothenburg, SWEDEN, [2]Institute for Clinical Sciences, Malmö, SWEDEN, [3]Institute for Clinical Sciences, Lund, SWEDEN.

Aim. An external alpha-particle irradiation system was designed and constructed enabling irradiation of cells. The radiosensitivity of prostate and pancreas cancer cells after alpha-particle irradiation was investigated and compared with external Cs-137 irradiations.Materials and Methods. The irradiation system was constructed based on a circular 241-Am dish on top at which well inserts containing cells growing in monolayer were placed. The source's total radioactivity, homogeneity, and alpha spectrum were measured via HPGe-detector, digital autoradiography, and PIPS-detector measurements, respectively. Monte-Carlo simulations were used for LET (linear energy transfer) spectras and dosimetry calculations. Cell survival studies were performed for both prostate and pancreas cancer cells. The cancer cell lines LNCaP, Capan-1, and HPAF-II were irradiated using the in-house developed external alpha-particle irradiator set-up. The cells were subjected to absorbed doses equal to 0, 1, 2, or 3 Gy during the alpha-particle irradiations, or up to 10 Gy regarding the Cs-137 irradiations. For evaluation of cell survival the tetrazolium-based WST-1 assay was used. After irradiation WST-1 solution was added to each well, incubated, and then measured for level of absorbance at 450 nm, indicating the amount of viable cells.Results. Compared to Cs-137 photon irradiations, a preliminary RBE of 4-5 is observed for the alpha-particle irradiations of the LNCaP and Capan-1 cells, at 37% cell survival. These studies are still on going and additional results, including results for HPAF-II, are continuously added.Conclusion. The study shows the feasibility to construct a long-lived relatively low cost alpha-particle irradiation set-up that could be used for cell survival studies in most laboratories. The results also shows a high degree of cell inactivation after alpha-particle irradiation for all three cancer cell lines, compared to Cs-137 irradiations.

PW103

Assessing radiobiological effects of low doses of ionizing radiation on zebrafish muscle by two-dimensional gel electrophoresis

J. Lemos[1], A. Campos[2], M. Carneiro[2], T. Ribeiro[2], F. Ponte[3], P. Costa[3], L. Cunha[4], A. Carvalho[5], L. Metello[4]; [1]ICBAS.UP & ESTSP.IPP, Porto, PORTUGAL, [2]CIIMAR/CIMAR.UP, Porto, PORTUGAL, [3]Júlio Teixeira SA., Porto, PORTUGAL, [4]ESTSP.IPP & IsoPor SA., Porto, PORTUGAL, [5]FCUP.UP & CIIMAR/CIMAR.UP, Porto, PORTUGAL.

Introduction: This work relates with the application of zebrafish - Danio rerio - to the study of radiobiological effects of low doses of ionizing radiation. In recent years, the use of zebrafish has grown considerably, pointing more and more as a very interesting model in biomedical research, essentially because of the level of homology shared with the human genome, complemented by an easy and reasonably affordable practical side. The two-dimensional gel electrophoresis (2DGE) is a method used for the analysis of complex protein mixtures from biological samples. This method allows the detection of differences in protein expression under different conditions, so allowing creating relations between those differences and the irradiations that were in their basis. The present work aimed at evaluating proteome changes in the zebrafish muscle caused by low doses of X-rays exposure. Material and Methods: Animals were externally irradiated with three distinct dose protocols (100 mGy, 500 mGy and 1.000 mGy). One day after the irradiation, the animals were sacrificed and a muscle sample was collected. 2DGE was then used to identify proteins that showed a differential expression after X-rays exposure. Results: About 85 ± 21 protein spots were identified in every gel. The statistical analysis of protein expression recognized differences between the control and the irradiated groups (27 spots to 1000 mGy; 22 spots to 500 mGy; 3 spots to 100 mGy). Most differentially expressed proteins were down-regulated in irradiated groups when compared to the control group. Conclusions: The present work seems to confirm that the 2DGE based methodology might be considered as an adequate analytical tool for study radiobiological effects at the molecular level in zebrafish. It has been found that a large number of proteins were down-regulated, suggesting that a remodelling of the muscle proteome occurs after the exposition to low doses of X-rays. Mass spectrometry analysis should be performed in order to allow the identification of those proteins that were affected by exposition to ionizing radiation. This identification would most probably contribute for a deeper insight concerning the metabolic and physiological consequences of the exposition to X-ray.

PW104

Gamma Camera Calibration for SPECT Based Quantitative Imaging with LU-177:

M. D'Arienzo[1,2], M. Cazzato[3], S. Ungania[3], L. Cozzella[1], G. Iaccarino[3], M. D'Andrea[3], L. Strigari[3], A. Fenwick[4], L. Johansson[4], M. Cox[4], P. De Felice[1]; [1]National Institute of Ionizing Radiation Metrology, Via Anguillarese 301, 00123 Rome, ITALY, [2]Department of Human Anatomy, Histology, Forensic Medicine and Orthopedics, Sapienza University of Rome, Via Borelli 50, 00161 Rome, ITALY, [3]Laboratory of Medical Physics and Expert Systems, Regina Elena National Cancer Institute, Via Elio Chianesi 53, 00044 Rome, ITALY, [4]National Physical Laboratory NPL, Hampton Road, Teddington, Middlesex, TW11 0LW, UK, UNITED KINGDOM.

Over the last 15 years 177Lu has been successfully applied to peptide receptor radionuclide therapy in the form of 177Lu-DOTATATE or 177Lu-DOTATOC to treat neuroendocrine tumors and other somatostatin-receptor expressing neoplasms. The general consensus is that the collection of quantitative data is a critical step in dosimetry and treatment planning in molecular radiotherapy. In fact, inaccuracies in absolute quantification are likely to result in reduced efficacy or increased incidence of adverse side effects. Absolute gamma camera calibration procedures are currently performed either in-air or in-water using a radionuclide source with a known amount of activity concentration. However, at present there are no validated standard protocols or any established methods for calibration and verification of system performance. The aim of this work was to develop and evaluate an approach to gamma camera calibration for absolute quantification in tomographic imaging with 177Lu. Calibration studies were performed on a Philips IRIX and Philips AXIS gamma camera. For both systems the calibration coefficient was assessed using four reference geometries: a point source in air, a 16 mL Jaszczack sphere surrounded by non-radioactive water, a 16 mL Jaszczack sphere in air and a 20 cm diameter cylinder filled with water uniformly mixed with radioactive 177LuCl. Attenuation correction was performed using Chang's algorithm while scatter correction was obtained applying the triple energy window technique. We validated our method in non-reference geometry using an anthropomorphic phantom

provided with liver cavity filled with 177LuCl. Acquisitions performed with the IRIX gamma camera provided better results, with agreements within 5% for all geometries for acquisitions at 208 keV. The use of a Jaszczak sphere in water provided sensitivity values capable of recovering the activity in anthropomorphic geometry within 1% for the 208 keV peak, for both gamma cameras. However, for both systems the activity in anthropomorphic geometry was recovered with an agreement in the range -11.9%/+7.1% for acquisitions at the 208 keV photo peak. As a general rule, acquisition at the lower photopeak provided results with larger deviations from the measured activity concentration. Scatter and attenuation play a major role at 113 keV and are likely to hinder an accurate absolute quantification. In the clinical practice acquisition on the higher photopeak are therefore recommended, provided that a good counting statistic can be achieved. The research leading to these results has received funding from the European Commission, Grant Agreement N° 217257 between the EC and EURAMET under the Seventh Framework Programme.

PW105
The Impact of Registration Method on 3D Dose Distributions

E. Page[1,2], J. Tipping[1], D. Hamilton[1], A. Robinson[2], D. Cullen[2], C. Oldfield[2]; [1]The Christie NHS Foundation Trust, Manchester, UNITED KINGDOM, [2]The University of Manchester, Manchester, UNITED KINGDOM.

Aims To evaluate the impact of registration algorithm on 3D dose distributions.**Materials**Three post 177Lu Dotatate therapy SPECT - CT image series were processed using four different registration algorithms.**Methods**The effect on the dose distribution of using direct rigid body registration of SPECT images was compared to using rigid body registration of the CT images and applying the transformation to the SPECT images. The effect of registering specific organs using a VOI mask on the SPECT images rather than using the whole images was also attempted. Additionally, non - rigid registration of the SPECT images using an affine registration algorithm was evaluated. Dose calculation was performed using MATLAB scripts written in house using the Voxel S Factor method.**Results**Preliminary results demonstrate that rigid body registration of the whole SPECT image is inadequate to register all organs intra-fraction in at least one patient example (clear misalignment of the spleen at the second time point). In another patient case SPECT to SPECT registration produced an improved alignment of the SPECT activity compared to CT-CT guided SPECT registration. A comparison of direct SPECT rigid body registration to affine registration found a difference in mean organ voxel dose that ranged from -6 to + 6% for one patient, but individual voxel doses of as much as much as -61 to 330% for a particular organ. Affine registration produced a better alignment of patient organs as a whole but distorted some of the smaller tumour activity distributions (resulting in a 'stretched' appearance not apparent in the original images).**Conclusions**Rigid body registration was inadequate for aligning all organs using the whole image. The decision to align the SPECT-CT time series using the SPECT or guided by the initial registration of the CT may need to be made on a patient by patient basis. Non- rigid body registration can produce overall improvement in organ alignment but may result in activity distribution and hence dose map distortion. Differences in registration method can result in a ± 6% difference in organ mean dose, but at an individual voxel level may result in differences of up to 330%. When considering heterogeneity of dose at the voxel level, the underlying method of registration can have a significant impact.

PW106
Optimal sampling times for quantitative imaging

M. KOTZASARLIDOU[1], M. COX[2], V. SMYTH[2], V. HATZIPAVLIDOU[1]; [1]"THEAGENIO" Cancer Hospital, THESSALONIKI, GREECE, [2]National Physical Laboratory (NPL), Middlesex, London, UNITED KINGDOM.

Introduction: According to the MIRD schema, mean absorbed dose D [Gy] in a volume of interest (VOI) is D = ÃS. Ã [Bq.s] is the area under the time activity curve (TAC) and S is the mean absorbed dose per unit cumulated activity [GyBq-1s-1]. The uncertainty for an estimate of Ã depends on the time points selected for fitting the TAC. A process for determining an optimal set of time points using the criterion that this uncertainty is minimized has been developed in the European joint research project MetroMRT (http://projects.npl.co.uk/metromrt/). Aim: This study tested the process of time point optimization using blood samples from patients to be treated with 131I for differentiated thyroid cancer (DTC). Materials & Methods: A tracer dose of 15 MBq of 131I was administered orally to seven patients with DTC and a 131I standard source was prepared simultaneously. Blood samples (2ml) were taken at four or five time points post administration. Aliquots of 1 ml were prepared from each blood sample and counted in a Captus® 3000 Well Counting System. Blood activities were normalized to the administered activity and the retention per ml of blood was calculated. A data set was selected as representative of the seven data sets. A biexponential model was fitted, the area under the TAC was estimated, and optimal time points using the above criterion were obtained. Four, five and six time points were so determined, TACs formed and standard uncertainties compared. This procedure was performed for activity uncertainties either constant or proportional to activity. Results: For constant activity uncertainties, reductions

(compared with the use of the original TAC based on the prescribed five time points) in TAC area uncertainty were 14%, 27% and 36% for 4, 5 and 6 optimal time points, respectively. For uncertainties proportional to activity, corresponding reductions were 22%, 31% and 38%. The largest time point selected did not vary with the number of points. Conclusions: TAC area uncertainties decrease usefully as the number of time points increases. One time point was consistently chosen to be as large as possible to ensure that the tail of the TAC is modelled accurately. This method of determining optimal time points will be tested further to confirm whether these favourable results apply more widely.

PW107

Comparison of Sequential SPECT and CT for Targeted Radionuclide Therapy Dosimetry

T. Li, K. Leong, E. Ao, **G. S. Mok**; University of Macau, Taipa, MACAO.

Aim: Previously we showed that non-rigid registration in sequential SPECT images improved the 3D dosimetric accuracy for targeted radionuclide therapy (TRT). This study aims to investigate the potential improvement on dose estimation when co-registered sequential SPECT and CT images are both available for image segmentation and registration. Materials and methods: We modeled 3 anatomical variations each with 3 In-111 Zevalin activity distributions, i.e., a population of 9 phantoms, using the digital 4D Extended Cardiac Torso (XCAT) phantom. Local deformations of the liver, kidneys, spleen and lung were modeled of up to 5 pixels/degrees with <5% volume change, combined with whole body rigid motion of up to 5 pixels/degrees of translation/rotation among imaging at 1, 12, 24, 72 and 144 hrs post-injection. One hundred and twenty-eight realistic noisy projections for a medium energy general purpose parallel-hole collimator were generated over 360° by an analytical projector based on a system calibration factor of 1.43×10-4 counts s-1 Bq-1, modeling attenuation, scatter and collimator-detector response and then reconstructed using OS-EM with 128 updates including full compensations. The corresponding attenuation maps of the phantoms served as the CT images. Using the 24-hr time point SPECT/CT images as the reference, we performed affine + b-spline non-rigid registration on organs semi-automatically segmented from sequential SPECT and CT images respectively. For CT registration, the acquired motion vectors were later applied to register the SPECT images. Voxel-by-voxel integration was performed on registered images over 5 time points, followed by convolution with a Y-90 dose kernel to generate dose images. Organ dose, differential and cumulative dose volume histograms (DDVH & CDVH) were generated for liver, spleen, kidneys and lungs. Results: For spleen, the organ dose error and normalized absolute error of DDVH were -9.22 ±6.59% and 32.71±7.34% for SPECT registration, while they were -3.63±1.47% and 20.08±5.67% for CT registration. For liver, the organ dose error and normalized absolute error were −2.19±2.81% and 22.57±10.18% for SPECT registration, while they were -2.44±1.19% and 14.68±6.01% for CT registration. For CDVH, the CT registration method generally approached more to phantoms with no misalignment as compared to SPECT registration for all organs. Conclusion: We conclude that if both sequential SPECT/CT scans are available, organ-based CT registration method can more effectively improve the 3D dose estimation as compared to SPECT registration. Sequential low dose CT scans might be considered to be included in the standard TRT protocol.

PW108

Radiation protectio impact of radioiodine therapy for hyperthyroidism after a patient specific dosimetric study

C. Canzi, V. Longari, M. Castellani, F. Buffoni, F. Zito, F. Voltini, R. Benti; Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico Milano, milano, ITALY.

In patients with hyperthyroidism, the treatment with ^{131}I should rapidly obtain a nonhyperthyroid status. There is an ongoing discussion on the establishment of the method to determine the activity that can be recommended for clinical practice: estimation (the so-called "fixed dose") versus calculation (based on radioiodine uptake measurements), however the optimization principle states that a patient should be given the minimum activity necessary to obtain the clinical goal. In our Nuclear Medicine Department all hyperthyroid patients are submitted to a patient specific pretreatment study to calculate the minimum activity to administer in order to achieve euthyroidism, in the case of nodular autonomies, and hypothyroidism, in the case of Graves' disease. Aim: to retrospectively evaluate the radiation protection impact of outpatients radioiodine therapies for hyperthyroidism after patient specific dosimetric studies, with respect to the standard administration of 600MBq (maximum activity allowed by Italian radiation protection law). Materials and methods: 503 patients were considered (187 Graves and 316 nodular autonomies, 364F, median age= 66y [range 17-89y], mean iodine uptake=39%). They all reached a nonhyperthyroid status within 1 year from the administration. Results: The median ^{131}I therapeutic orally administered activity was 396 MBq (10.7 mCi) with a range between 66 and 629 MBq (1.8-17.0 mCi). The total administered activity was 214 GBq (5.8 Ci). If the standard activity of 600 MBq had been administered to all patients the total activity would have been 302 GBq (8.2 Ci), an amount 41% greater than the really used one. This obviously acts also on the patient mean effective dose

equivalent and on the mean absorbed dose to the stomach wall (critical organ for ^{131}I iodide) (ICRP 53) that were 6 Sv instead of 9 Sv and 0.20 Gy instead of 0.28 Gy respectively, with a maximum of dose saving (8 times) for the patient who was given the minimum activity of 66 MBq. The reduction of ^{131}I administered activity also acts on the radiation exposure of the nuclear medicine unit staff and of population: the mean dose rate at 1 m at the dismission time is 12 μSv/h instead of 20 μSv/h. This approach involves also the environment, as in the first 24 hours the 60% of the administered activity is excreted by the body. Conclusion: the application of a patient specific pretreatment dosimetric study can reduce of more than 40% the radiation protection impact of radioiodine treatments of hyperthyroidism with optimal clinical results guaranteed.

PW109

Estimates of exposure dose to the nuclear medicine staff from inpatient 131I therapy of differentiated thyroid carcinoma

B. Liu, R. Tian; Department of Nuclear Medicine, West China Hospital, Sichuan University, Chengdu, CHINA.

Inpatient 131I therapy is still necessary for some patients with differentiated thyroid carcinoma (DTC). It is necessary to consider the potential radiation burden to the nuclear medicine staff, the present study was thus designed to estimate the radiation exposure to the nuclear medicine staff from inpatient 131I therapy of DTC on the basis of the actual measurements of patient-specific whole body dose-rates.Forty-seven patients (7 males, 40 females; age range: 23-56 years, average age: 41±13 years) with DTC were randomly and prospectively recruited in this study. At 1, 12, 24, 48, and 72 h after administration of 3.7 GBq of 131I, whole body dose-rate was serially measured with a radiation-survey meter at 1.0 m from the upright patients and the DR-time curve was fitted by exponential function. On the assumption that a nuclear medicine physician or nurse typically spends 10 min at a distance of 1.0 m per day during the first 5 days after administration, the nuclear medicine staff's exposure dose was estimated.The mean whole body dose-rate at 1.0 h after administration of 131I was 27.88 μSv/h/GBq, ranging from 15.81 to 46.48 μSv/h/GBq. The exposure dose to a nuclear medicine physician per contacting a DTC patient was predicted to be 4.02-28.35 μSv.The predicted exposure doses to the nuclear medicine staff are relatively low from short periods of contact with DTC patients undergoing 131I therapy.This work was supported by the National Natural Science Fund of China Grant No. 81401445, 81471693.

PW110

Correlation of Clinical Outcomes with Bremsstrahlung and Y-90 PET/CT Imaging Findings Following Y-90 Radiation Synovectomy

T. Barber[1,2], A. Powell[3], M. Cherk[1,2], K. Yap[1], V. Kalff[1,2]; [1]Department of Nuclear Medicine & PET Centre, The Alfred Hospital, Melbourne, AUSTRALIA, [2]Department of Medicine, Monash University, Alfred Hospital Campus, Melbourne, AUSTRALIA, [3]Department of Rheumatology, The Alfred Hospital, Melbourne, AUSTRALIA.

Aim: To correlate clinical outcomes following radiation synovectomy with bremsstrahlung and Y-90 PET/CT imaging findings.Methods: A total of 48 joints in 39 patients underwent bremsstrahlung planar and Y-90 PET/CT imaging following radiation synovectomy. The Y-90 distribution pattern on bremsstrahlung planar imaging was classified as diffuse or non-diffuse and compared with the intra or extra-articular location of activity on Y-90 PET/CT. Treatment response was assessed by patients and clinicians at 6 months using a composite change index (CCI) with a score ranging from 0-12. A successful overall response was defined as CCI > 6. In patients who underwent bremsstrahlung SPECT, side by side image comparison with PET was performed with image quality/resolution compared and scored using a five point scale.Results: Bremsstrahlung planar images were classified as diffuse in 31/48 (65%; 95% CI: 51-78%) and non-diffuse in 17/48 (35%; 95% CI: 22-49%). There was no association between overall treatment response in patients with diffuse compared to non-diffuse bremsstrahlung planar imaging patterns [8/31 (26%) vs 6/17 (35%) p = 0.49]. PET/CT confirmed an intra-articular location in all 31 diffuse scans and an extra-articular location in three non-diffuse scans. Of the three patients with extra-articular activity none had any response to treatment. Excluding these three patients, there remained no association between the bremsstrahlung planar imaging pattern and overall treatment response (p = 0.25). Of the 41 joints imaged with SPECT, PET image quality was classified as superior to SPECT in 40 and inferior in one. In one patient with extra-articular activity on PET/CT, SPECT/CT was unable to definitively localise the activity to the intra or extra-articular space.Conclusion: The distribution pattern on bremsstrahlung planar imaging did not correlate with overall clinical outcome following radiation synovectomy in our study population. However, a non-diffuse planar imaging pattern should be further assessed with Y-90 PET/CT to exclude extra-articular activity with PET providing superior image quality compared to SPECT.

Acquisition parameters optimization for imaging with Ra-223

A. Corazza[1,2], G. Cicoria[2], F. Zagni[2], G. Lucconi[1,2], D. Pancaldi[2], M. Marengo[2]; [1]Postgraduate School in Medical Physics, University of Bologna, Bologna, ITALY, [2]Medical Physics Department, University Hospital "S.Orsola - Malpighi", Bologna, ITALY.

Introduction: Ra-223 is an alpha emitter radionuclide with an half life of 11.43 days and a reduced emission of betas and gammas (about 5%) per decay. Its chemical affinity with calcium and the high dose delivered locally make Ra-223 dichloride (Xofigo®) a relevant radiopharmaceutical for targeting areas of increased bone turnover (standard injected activity is 50 kBq/kg). This work studied acquisition parameters for post-treatment Ra-223 imaging. Material and methods: Images of Ra-223 were acquired using three windows, at 82, 154 and 269 keV with a width of 10%, 10% and 8%, and using Low Energy High Resolution (LEHR), Medium Energy Low Penetration (MELP) and High Energy (HE) collimators. The Line Spread Function (LSF) was measured by imaging for 120 minutes a 1.3 mm capillary, filled with 190 kBq of Ra-223 and placed at a distance of 10 cm from the collimator. Activity was carefully measured using a MP-DC activity meter (Mecmurphil, Italy), specifically calibrated for Ra-223. Image contrast was evaluated separately for the three windows, varying the width of the 82 keV peak from 10% to 20%. Planar images of a Jaszczak phantom, with the "rods" sector positioned at several distances on top of different collimators were acquired for > 12 hours. Static images of the rods sector were then analyzed using ImageJ. Results: Visual inspection on the three images showed that MELP collimators produce an acceptable image quality. For MELP and HE collimators, the FWHMs were 12 and 13 mm and the FWTMs were 26 and 28 mm. Quantitative evaluation of MTF was possible only for MELP (90% and 50% at 0.12 cm-1 and 0.36 cm-1), since for HE collimator the image was affected by evident artifacts. The sensitivity measured were of 2.30, 0.35 and 0.24 cps/kBq with LEHR, MELP and HE collimators respectively. Analysis on rods images showed that extending window width from 10% to 20% reduced contrast by 15% and increased counts by 79%. Adding peaks at 154 keV and 269 keV reduced contrast but increased sensitivity by 77%. Conclusions: Image quality obtained with Ra-223 is realtively poor, but sufficient to confirm the biodistribution of the radiopharmaceutical. According to our results, MELP collimators should be used; most of the information is acquired in the 82 keV window, the 154 and 269 keV contributing to total statistics but with a limited contrast modulation.

PW112

Comparison and evaluation of the effectiveness of α- [Ra-223 Dichloride] and β- particle emission treatments [combined Re-186 HEDP / Sr-89 Chloride and/or Sm-153 EDTMP/ Sr-89 Chloride] on Tc-99m-MDP scintigraphic series in pts with painful osseous metastases due to castration-resistant prostate adeno-carcinoma

G. S. Limouris[1], M. Paphiti[2], S. Synefia[1], M. Lyra[1], L. Moulopoulou[1], V. R. McCready[2]; [1]Nuclear Medicine Div - I Radiology Dept-, 'Aretaieion' Hosp, Athens Univ Medical Faculty, Athens, GREECE, [2]Nuclear Medicine Dept, Royal Sussex County Hosp, Brighton, UNITED KINGDOM.

Aim: We aimed, by the present to evaluate and highlight the efficacy of the therapeutic application of alpha radiation on follow-up [Tc-99m] MDP scintigrams and compare them with respective scans in patients after beta-emission treatments, using combined Sm-153 EDTMP / Sr-89 Chloride, since improvement in follow up [Tc-99m] MDP scintiscans after the use of beta-emission, rarely had been observed in the pastMaterial and Methods: In the last decade, approx 8000 whole-body [Tc-99m]MDP bone scintiscans have been performed on a follow up basis program. Forty-two (group A) pts with known history of hormone-resi-stant prostate adenocarcinoma were treated with combined Sm-153 EDTMP/ Sr-89 Chloride application, in a dosage of 37 MBq x kgr $^{-1}$ and 148 MBq respectively. Approx a year later, in 4(group B) out of 42 pts, Ra-223 Dichloride was additionally injected in a dosage of 50 x kgr $^{-1}$ in monthly sessions x 6, following the same MDP whole-body follow up basis program. The scintigraphic series of both groups were compared and evaluated by two independent Nuclear-Medicine-physicians. Dosimetry was performed in both cohorts from planar images on gamma energy windows of Sm-153 (27.9 %) and Ra-223 (1.1%). Absorbed doses calculations were performed using OLINDA 1.1 software. Blood samples were collected 0.30 min, 2, 4, 8 and 24hrs p.i. .Urine [24 hrs] collection was performed.Results: The visual (qualitative) comparison of the MDP follow up series [120 defects, before therapy] in the β-emission irradiated 42 pts depicted in only 2 cases an obvious reduction of the osseous defects [117/120, 32 mo post therapy, $p > 0.5$]. The comparison in the α-emission irradiated 4 pts [18 defects, before therapy] showed a marked reduction [12 defects, 8 mo post therapy, $p < 0.01$]. The dosimetric (quantitative) comparison for Sm-153/Sr-89 vs Ra-223 was

0.018 Gy/MBq and 1.16 Gy/MBq for osteogenic cells respectively, whereas for red marrow was 0,004 Gy/MBq and 0.14 Gy/MBq.Conclusion: The qualitative (visual) study of these two MDP follow up series assesses the efficacy and superiority of the effectiveness of a-particles due to marked LET differences between β- and α- treated cohorts. The use of Ra-223 Dichloride in castration-resistant prostate adeno-carcinomas in these preliminary results and the scintimaging follow-up, besides the clinical course of the disease, proved that reasonably by the use of α-emission the concept "palliative treatment" might be substituted by "curative treatment" according to the conceptual meaning of the Greek word for therapy, i.e. ίασις (iasis).

PW113

Clinical benefit of routine application of Rhenium-188-HEDP in patients with painful bone metastases from prostate or breast cancer

R. Lange[1], F. Overbeek[1], A. M. van den Berk[1], J. M. H. de Klerk[1], P. C. M. Pasker-de Jong[1], R. ter Heine[1,2], M. M. L. van der Westerlaken[1], C. J. Rodenburg[1], N. H. Hendrikse[3], H. J. Bloemendal[1]; [1]Meander Medical Center, Amersfoort, NETHERLANDS, [2]Radboud University Medical Center, Nijmegen, NETHERLANDS, [3]VU University Medical Center, Amsterdam, NETHERLANDS.

Introduction: At our hospital, the therapeutic radiopharmaceutical Re-188-HEDP has been developed for treatment of painful osteoblastic bone metastases. Since Re-188-HEDP is an unlicensed radiopharmaceutical, proper pharmacovigilance is of utmost importance. This prospective study evaluates the effect of Re-188-HEDP on pain palliation, quality of life and hematological toxicity when applied in routine clinical care. Methods: Patients were eligible for inclusion when they received Re-188-HEDP treatment for treatment of painful bone metastases of prostate or breast cancer as a part of routine clinical care in our hospital. Pain palliation was assessed using the visual analogue pain score (VAS) and measuring opioid intake before treatment and 4 and 8 weeks afterwards. A response in pain palliation was defined as a minimal decrease of two points in VAS after either 4 or 8 weeks and no increase in opioid intake. Quality of life was evaluated using the EORTC QLQ-C30 questionnaire before treatment and 4 and 8 weeks afterwards. Changes in each scale were assessed and response in quality of life was defined as a minimum increase of ten points on the global health status/QoL-scale after either 4 or 8 weeks.Nadirs from blood counts of thrombocytes and leukocytes were used to assess hematological toxicity, graded according to the CTCAE criteria. Results: Seventy-five patients with painful metastatic prostate (n=50) or breast (n=25) cancer were included in this study, of which 38 and 42 patients were evaluable for pain palliation and quality of life, respectively. Twenty-four patients received multiple injections. For this analysis only first treatments were evaluated. The response rate on pain reduction was 66%. VAS-scores decreased significantly at 4 weeks ($p<0.01$) and 8 weeks ($p=0.01$), with a mean(±SD) decrease of 2.9±3.1 and 2.3±3.6 points, respectively. For the overall quality of life the response rate was 69%. The mean(±SD) increase of the global health status/QoL was 16±21.9 ($p<0.01$) at 4 weeks and 8±25.1 ($p=0.06$) at 8 weeks, respectively. Significant improvement was seen in several symptom scales. No significant differences were observed between the responses in patients with prostate and breast cancer.The treatment was well tolerated. Hematological side effects were mild and transient. Grade III thrombocytopenia and leukopenia occurred in 2 (3.8%) and 1 (1.8%) patient(s), respectively. There were no grade IV hematological adverse effects. Conclusion: The clinically relevant response of Re-188-HEDP application on pain reduction and quality of life and the limited side effects support the use of Re-188-HEDP in routine clinical care.

PW114

Does cooling of the salivary glands reduce uptake of radiolabeled PSMA-ligands?

F. C. Gaertner, H. Ahmadzadehfar, R. A. Bundschuh, S. Kürpig, E. Eppard, M. Essler; University Hospital Bonn, Bonn, GERMANY.

Aim: One major concern of PSMA-targeted PRLT (peptide radionuclide ligand therapy, e.g. using Lu-177-labeled PSMA-binding constructs) in patients with advanced castration-resistant prostate cancer (CRPC) is xerostomia due to the high physiologic uptake of PSMA-ligands in the salivary glands. We evaluated if a physical intervention (cooling) has a significant impact on tracer uptake in the salivary glands using PET imaging with a Ga-68-labeled PSMA-ligand. Patients and Methods: 92 patients undergoing PET/CT with Ga-68-HBED-CC (PSMA-ligand) were evaluated. 44 patients started cooling the salivary glands using ice-packs (4°C) about 15 minutes before tracer injection until the start of the PET acquisition. The remaining 48 patients did not use cooling. Injected activity was approx. 2 MBq / kg body weight. SUVmean and SUVmax were measured in the salivary and lacrimal glands, as well as physiologic tracer uptake in the brain, mediastinum, liver, spleen, muscle, bone, kidneys and bladder contents. Results: 34 patients with high tumor load were excluded from analysis due to concerns of a possible tumor sink effect, reducing uptake in normal organs. Therefore, 25 patients with cooling and 33 patients without cooling could be analyzed. With cooling, SUVmean was reduced by 12% in the parotid glands (11.03 ± 2.59 vs 12.60 ± 3.06; $p <$

0.01) and by 15% in the submandibular glands (12.05 ± 2.98 vs 14.21 ± 4.24; $p < 0.01$). Regarding SUVmax, the values were 17.14 ± 4.04 vs 19.46 ± 4.36; $p < 0.01$ for the parotid glands and 18.36 ± 4.49 vs 22.42 ± 6.67; $p < 0.01$ for the submandibular glands. Also, the ratios SUVmax-to-liver-background showed significant differences for the parotid glands (4.16 ± 1.04 vs 5.01 ± 1.75; $p < 0.01$) and for the submandibular glands (4.54 ± 1.22 vs 5.33 ± 1.64; $p < 0.01$). On the other hand, no significant differences were observed for the lacrimal glands, sublingual glands, and the remaining normal organs mentioned above ($p > 0.05$). Conclusion: Cooling of the salivary glands resulted in a small, but nevertheless significant reduction of PSMA-ligand uptake in the parotid and submandibular glands. Therefore, cooling of the salivary glands seems to be a simple, non-invasive approach to achieve a slight reduction of radiation dose to the salivary glands when performing PRLT with radiolabeled PSMA-ligands.

PW115

The impact of imaging and dosimetry methodology on ^{18}F NaF PET-based molecular radiotherapy treatment planning

A. M. Denis-Bacelar[1], G. D. Flux[2]; [1]Institute of Cancer Research, London, UNITED KINGDOM, [2]Royal Marsden Hospital, London, UNITED KINGDOM.

Aim: ^{18}F NaF PET/CT scans are increasingly used for patients with bone involvement. Comparable mechanisms of uptake with radionuclide-labelled bisphosphonates and ^{223}Ra, make sodium fluoride scans suitable for dosimetry-based treatment planning in bone targeted therapies. The aims of this study were to investigate the influence of attenuation correction and dosimetry calculation methods upon the prediction of the absorbed doses to bone for typical bone-seeking radiopharmaceuticals (^{153}Sm-EDTMP, ^{177}Lu-EDTMP and ^{188}Re-HEDP).Materials and Methods: ^{18}F NaF PET/CT scans from 9 patients with prostate cancer and suspected or known bone involvement were obtained from the Cancer Imaging Archive [1]. The PET scans were reconstructed using a RAMLA iterative OSEM algorithm with 3 iterations and 33 subsets, with (CTAC) and without (NAC) CT attenuation correction. Voxel absorbed doses were predicted for the three radionuclides using convolution and full Monte Carlo (MC) methods from the NAC and CTAC scans. Decay spectra were obtained from the RADTABS/MIRD software. Dose-kernels for a uniform soft-tissue medium were generated using an in-house EGSnrc/EGS++ MC code and convolved with the PET scan normalised to 1 MBq·s. Full MC simulations were carried out in EGSnrc/EGS++ from the PET uptake distribution and the CT segmented into cortical bone, spongiosa, soft-tissue, adipose-tissue and air according to the Hounsfield units. The energy in each voxel was converted into absorbed dose assuming physical half-life and 1 GBq of activity for all radionuclides. Results: Full MC shows that 67%, 67% and 66% of the total energy was deposited in cortical bone for ^{153}Sm, ^{177}Lu and ^{188}Re respectively when the absorbed doses were predicted from attenuation-corrected scans. These were reduced to 56%, 58% and 55% when the non-attenuation-corrected scans were used. Preliminary comparisons show that the mean absorbed dose deposited in cortical bone obtained from the MC predicted distribution was underestimated by 84%, 47% and 45% for ^{153}Sm, ^{177}Lu and ^{188}Re respectively when the NAC scans were used. Ratio maps between the MC and convolution distributions show mean ratios in cortical bone of 1.04(1.4), 1.0(1.4) and 0.93(1.3) for ^{153}Sm, ^{177}Lu and ^{188}Re respectively.Conclusion: ^{18}F NaF PET/CT bone scans have the potential to be used for treatment planning in molecular radiotherapy of bone metastases. Therefore, accurate knowledge of the impact of imaging and dosimetry methods upon the prediction of absorbed doses is required. On-going work comprises the improvement of the CT segmentation to better define source and target volumes, including the metastatic lesions.[1] http://www.cancerimagingarchive.net/

PW116

Radiation Toxicity Concerning Salivary and Lachrymal Glands Caused by Peptide Radioligand Therapy Using a Lu-177 PSMA Inhibitor (I & T) in Patients with Metastasized Prostate Cancer: First in Human Studies

A. Özkan[1], C. Schuchardt[2], H. Kulkarni[2], M. Shahinfar[2], M. Sayeg[2], R. Baum[2]; [1]Yildiz Technical University, Physics Department, Istanbul, TURKEY, [2]Zentralklinik Bad Berka, Theranostics Center for Molecular Radiotherapy and Molecular Imaging (PET/CT), Bad Berka, GERMANY.

Aim: PRLT is a promising new therapy option in metastatic, castration resistant prostate cancer (mCRPC). The objective of this study was to determine the uptake, half-life (kinetics) and the mean absorbed dose in salivary and lachrymal glands during PRLT of patients with mCRPC using a Lu-177 labelled DOTAGA-PSMA inhibitor (I & T). Methods: 10 mCRPC patients (aged 74+/-8 years) were examined. The injected activity was 5.9+/-1.3 GBq Lu-177 PSMA I & T. Post-therapeutic dosimetric assessments of salivary glands and lachrymal were performed (MIRD scheme). Planar whole body scans at 0.5, 3, 24, 48 and 72 h p.i. were analyzed by region of interest (HERMES WHOLE BODY DISPLAY). Time-dependent tissue activities were determined with Microsoft EXCEL™. Half-life (based on fit to exponential function) and cumulated activity of the glands were calculated

with ORIGIN PRO 8.1G™, mean absorbed doses were estimated using the OLINDA EXM™. Uptakes were expressed as percent of injected activity (% IA). The mean target volumes were measured using a 64 slice CT scanner or taken from literature: 14 ml for the right, and 16 ml for the left parotid gland and 1.2 ml for lachrymal glands. Results: High uptake of the tracer was found in the salivary glands as well as significant uptake in the lachrymal glands in all 10 patients. The time-dependent tissue activities showed an exponential decline after 20 h p.i. Maximum uptake in the parotid glands was 1.2% IA (immediately after administration) and decreased with a mean half-life of 38+/-24 hours (11-118 hours). Based on CT volumes, the absorbed dose to parotid glands was 8+/-6 Gy (maximum 23 Gy). Lachrymal glands showed a maximum uptake of 0.2% IA and a fast wash-out with half-lives of 36+/-16 hours (12-71 hours). Assuming a mean volume of 1.2 ml, a mean absorbed dose of 9.5+/-4.9 Gy (5-25 Gy) was estimated. Clinically, no adverse effects were observed (follow-up up to 24 months) in any of the patients concerning salivary gland function (no dry-eye-dry-mouth syndrome). Conclusions: As no side effects occured, we conclude that PRLT using Lu-177 PSMA I & T exhibits no (or very low) toxicity to the salivary and lachrymal glands which is most probably due to the fast wash-out and the low beta energy of Lu-177. Further studies in a larger patient cohort as well as serial salivary gland scintigraphies are planned to confirm the safety of PRLT in mCRPC.

PW118

Response Evaluation Criteria in Solid Tumours (RECIST) in a group of patients submitted to Y-90 resin microspheres radioembolization

L. G. da Costa, J. A. M. Santos, B. Gonçalves, L. Violante, F. G. S. Lopes, O. Soares, J. P. Teixeira, I. S. Lucena, A. F. Costa, L. H. T. Duarte; Instituto Portugues de Oncologia do Porto Francisco Gentil, EPE, Porto, PORTUGAL.

Aim: One reports on eligibility, safety and response to treatment of a group of patients with primary tumours and metastatic hepatic disease treated with 90-Y resin microspheres (Sirtex Sir-Spheres). Matherial and Methods: All cases referred to our department for 90-Y resin microspheres treatment between December 2011 and January 2015 were retrospectively reviewed. All patients, except hepatocellular carcinomas, had previous 18-F:FDG PET/CT scans for disease stratification. The location of the primary tumour was accessed as well as a previous 99m-Tc:MAA distribution evaluation to envisage the possibility of gastric reflux, pulmonary shunt, and Y-90 microspheres distribution inside the liver. RECIST (Response Evaluation Criteria in Solid Tumours; version 1.1) response after 3 months was evaluated for all treated patients. Results: Thirty three (33) patients were referred for radioembolization: colorectal tumours (15 patients), hepatocellular carcinoma (12), breast cancer (3), cholangiocarcinoma (1), Hepatic Neuroendocrine Tumour (1), and medullar thyroid carcinoma (1). Eight (8) patients were excluded: metastatic disseminated disease accessed by PET/CT (2), Pulmonary shunt > 20% (2), absence of 99m-Tc:MAA in the tumour (3), and more localized disease than it was previously predicted (1). Twenty five patients were treated (18 to the two lobes and 7 to one lobe) with activities ranging from 0,7 GBq to 2,4 GBq. Pulmonary shunts were found to be between 2% and 15%. Patients were assessed by RECIST: partial response (8), stable disease (7), and disease progression (8). No patient presented a complete response. One patient had disease progression and died before evaluation could be completed. Some lateral effects were observed. Conclusion: These results showed a partial response or stable disease in two thirds of this group of patients. The evaluation result showed a reasonable agreement with those reported so far in the literature [1-3].

PW119

Optimising methodologies for comparison of ^{99m}Tc-MAA and ^{90}Y-microsphere distributions

A. J. Craig[1], I. Murray[1], A. M. Denis-Bacelar[2], N. Khan[3], A. Maenhout[3], B. Rojas-Fisher[4], L. Hossen[4], G. Flux[1]; [1]Royal Marsden NHSFT & The Institute of Cancer Research, Sutton, UNITED KINGDOM, [2]The Institute of Cancer Research, Sutton, UNITED KINGDOM, [3]Chelsea & Westminster NHSFT, London, UNITED KINGDOM, [4]Royal Brompton NHSFT, London, UNITED KINGDOM.

The aim of this work is to optimise a methodology to assess the extent to which ^{90}Y-microsphere distribution can be predicted by the ^{99m}Tc-MAA study for Selective Internal Radiation Therapy (SIRT). It is postulated that differences in the pre-therapy ^{99m}Tc-MAA SPECT and post-therapy ^{90}Y-bremsstrahlung SPECT scans will either be due to inherent differences in the respective imaging processes or due to differences in the underlying distribution of the MAA and microspheres.

Therefore any comparison methodology should be independent of the differences in the imaging processes. Method: ^{99m}Tc-MAA SPECT scans were convolved with a 20mm Gaussian point spread function in order to match them with the resolution of the ^{90}Y-bremsstrahlung scans. The blurred ^{99m}Tc-MAA SPECT scans were assumed to represent a dataset of bremsstrahlung scans known to have the same underlying distribution of activity as the original ^{99m}Tc-MAA SPECT scans. The original and blurred ^{99m}Tc-MAA SPECT scans were used as a control dataset to test comparison methodologies. Spearman rank correlation and histogram intersection were tested as comparison methodologies. 12 patients with either primary liver cancer or liver metastases underwent ^{90}Y-microsphere SIRT therapy. The ^{99m}Tc-MAA and ^{90}Y-bremsstrahlung SPECT scans from these patients were then compared. Results: Spearman rank values for the control dataset with matching distributions were in the range 0.88-0.94. Control values for the histogram intersection were in the range 0.48-0.72. Histogram intersection comparisons were not undertaken for ^{99m}Tc-MAA and ^{90}Y-bremsstrahlung SPECT scans as the control measured highlighted this measure as unreliable. Spearman rank coefficients for comparing ^{99m}Tc-MAA and ^{90}Y-bremsstrahlung scans were 0.32-0.82. Conclusion: Analysis of the control dataset validated the Spearman rank correlation coefficient as a test invariant to the differences in the imaging processes. However, the control dataset showed the histogram intersection not to be independent of the imaging process and thus not appropriate for this use. Spearman rank correlation coefficients of pre and post therapy SPECT scans showed a large range in the distribution differences.

PW120

Comparison of absorbed dose calculations for non-uniform activity distributions obtained via 90Y-PET/CT after liver radioembolization

M. D'Arienzo[1,2], M. Tapner[3], E. Spezi[4], N. Patterson[5], P. Chiaramida[6], L. Filippi[7], M. Ahrens[8], T. Paulus[9], O. Bagni[7]; [1]National Institute of Ionizing Radiation Metrology, Via Anguillarese 301, 00123 Roma, ITALY, [2]Department of Human Anatomy, Histology, Forensic Medicine and Orthopedics, Sapienza University of Rome, Via Borelli 50, 00161 Rome, ITALY, [3]Research & Development at Sirtex, North Sydney 2060, NSW, Australia, AUSTRALIA, [4]Cardiff University, Cardiff CF10 3XQ, UNITED KINGDOM, [5]Department of Medical Physics, Velindre Cancer Centre, Velindre Road, Whitchurch, Cardiff, CF14 2TL, UNITED KINGDOM, [6]GE Healthcare Medical Systems, Milano, ITALY, [7]Nuclear Medicine Department, Santa Maria Goretti Hospital, Latina, ITALY, [8]Philips GmbH Innovative Technologies, Research Laboratories, Pauwelsstr. 17, 52074 Aachen, GERMANY, [9]Philips Technologie GmbH Innovative Technologies, Research Laboratories, Pauwelsstr. 17, 52074 Aachen, GERMANY.

Hepatic selective internal radiation therapy (SIRT) using either resin or glass 90Y microspheres is an established catheter-based therapy for the treatment of unresectable primary and metastatic tumors with the potential of delivering a high radiation dose directly to tumor areas meanwhile sparing healthy tissues. In the last years 90Y PET/CT has been shown to provide a superior post-administration evaluation of the treatment due to its improved spatial resolution. Furthermore activity maps obtained from quantitative PET data can be converted into absorbed dose maps, thus predicting treatment efficacy. In recent years there has been an intensifying debate revolving around the most accurate dosimetric approach for three-dimensional dosimetry in molecular radiotherapy. The aim of the present work is to evaluate the absorbed dose to lesions from 90Y-PET images using different dose calculation algorithms including: I) Direct Monte Carlo radiation transport using Raydose II) Kernel-convolution using Philips Stratos III) Local deposition algorithm IV) Monte Carlo technique (MCNP) considering a uniform activity distribution V) MIRD approach. A body-shaped anthropomorphic phantom with lung, liver and spine inserts was used in the present study. A cylindrical home-made PMMA insert was manufactured and fixed into the liver insert to simulate a hepatic lesion (17 mL, approximately). Measurements in anthropomorphic geometry were performed using a GE Discovery ST PET/CT scanner with a 6:1 tumor to background activity concentration ratio. The first scan was performed with an activity concentration of 5.5 MBq/mL for the lesion insert and 0.89 MBq/mL for the liver background. The anthropomorphic phantom was then acquired at days 4, 5, 6 and 12 (according to the scanner availability) down to an activity concentration of 0.31 MBq/mL for the lesion insert and 50 kBq/mL for the liver background. Preliminary results indicate that despite 90Y-PET is likely to provide high-resolution images, the 90Y low branch ratio may produce non-uniform activity maps, possibly leading to activity and dose underestimations when a non optimised image reconstruction protocol for 90Y is used. All dose algorithms provided satisfactory results, the worst case scenario providing an agreement between absorbed dose evaluations within 20%. Additional work is needed towards the development of 90Y specific PET reconstruction protocols to allow proper image quantification for dosimetry. The research leading to these results has received funding from the European Commission, Grant Agreement N° 217257 between the EC and EURAMET under the Seventh Framework Programme

Quantitative Texture Analysis on a PET-CT… With Texture Standardization in Mind!

J. Cortes-Rodicio, G. Sanchez-Merino, R. Lope-Lope, J. Ruiz-Pomar, T. Martin-Gonzalez, M. Garcia-Fidalgo; Osakidetza, Vitoria-Gasteiz, SPAIN.

INTRODUCTION AND OBJECTIVES: Texture parameters are important features commonly used for pattern recognition, image classification and, more recently in the field of "radiomics", where more useful information might be extracted from medical images. Anyway, texture quantification is affected by many technical and physiological factors. The purpose of this work is to study the textural performance of a Philips Gemini TF PET as a function of the reconstruction protocol and FDG activity concentration to set a baseline for future clinical heterogeneity studies. METHODS AND MATERIALS: Nineteen series from a cylindrical phantom filled with different FDG activity concentration (max. 23,5kBq/mL, min. 0,66kBq/mL) have been acquired in a Philips GEMINI TF PET/CT. For each acquisition the raw PET data were reconstructed using three different protocols: WB-CTAC (BLOB-OS, TOF, 4mm), HN-CTAC (BLOB-OS, TOF, 2mm) and WB-CTAC-R3D (3DRAMLA, non-TOF, 4mm). Seventy-two texture features were extracted using Chang Gung Image Texture Analysis toolbox for MatLab. Fractal dimension and lacunarity features were calculated using the free plugin FracLac of ImageJ. On the one hand, for each texture feature and reconstruction protocol, the variability with FDG activity concentration was calculated as the ratio between the mean values divided by the standard deviation. On the other hand, a Pearson correlation analysis between the fractal features and activity concentration were performed using StatGraphics Centurion XVI software. RESULTS: Only nine of the seventy-two texture features analyzed show small variability (<5%) with activity concentration. These are entropy (Haralik-1973, Sun-1983, Horng-2002); short-run-emphasis and run-percentage (Loh-1988); the homogeneity, intensity, inverse-difference-moment and code-entropy (Horng-2002); and short-zone-emphasis and zone-percentage (Thibault-2009). These features seem to be suitable for textural quantification of tumors and further classification of them. Features presenting large variations are not recommended for heterogeneity quantification. With respect the fractal dimension and lacunarity features, we find a significant statistical quadratic and linear correlation, respectively ($p<0.05$) between them and the activity concentration for all the reconstruction protocols. CONCLUSIONS: This study shows that it is feasible to apply textural and fractal analysis methods to study the heterogeneity of tumors, but taken into account the technical factors that will lead to variations on the results, in our case activity concentration and reconstruction protocol. It is mandatory to establish a reference performance of different PET in order to allow comparison of multicenter studies. Anyway, further studies should be carried out to improve the statistical power of the analysis.

P002

Performance assessment of the Albira tri-modal pre-clinical PET system

A. Attarwala[1], Y. W. Karanja[1], C. Romanó[1], M. Roscher[2], C. Maaß[1], B. Wängler[2], G. Glatting[1]; [1]Medical Radiation Physics/Radiation Protection, Universitätsmedizin Mannheim, Medical Faculty Mannheim, Heidelberg University, Mannheim, GERMANY, [2]Molecular Imaging and Radiochemistry, Institute for Clinical Radiology and Nuclear Medicine, Medical Faculty Mannheim, Heidelberg University, Mannheim, GERMANY.

Aim: Quantitative molecular imaging with a pre-clinical positron emission tomograph (PET) is a prerequisite in treatment planning, monitoring and development of new diagnostic and therapeutic radiopharmaceuticals. This study analyzes the performance characteristics of the Albira PET sub-system and measures the response of the system for the commonly used radionuclides (18F and 68Ga) in small animal imaging. Materials and Methods: The Albira tri-modal system (Bruker BioSpin MRI GmbH, Ettlingen, Germany) is a pre-clinical device with a PET, SPECT and CT. The PET sub-system is made up of single continuous crystal detectors of lutetium yttrium orthosilicate (LYSO) coupled to position-sensitive photomultipliers (PSPMTs). The detector assembly consists of three rings with each ring having 8 detector modules. The trans-axial field of view (FOV) is 80mm and the axial FOV is 148mm.Imaging was performed with the NEMA NU-4 image quality phantom (Data Spectrum Corporation, USA) having five rods with diameters 1-5mm and a uniform central region. Measurements with 18F and 68Ga were performed with a starting activity concentration of 500kBq/ml and a list mode acquisition of 10h.An energy window of 358-664keV and a coincidence time window of 5ns were selected. The data were

reconstructed with a maximum likelihood expectation maximization (MLEM) algorithm; voxel size of 0.5mm with increasing iterations from 5 to 50 (step-size 5) and corrections for randoms/scatter was included within the system. System sensitivity, count rate linearity, algorithm convergence and recovery coefficients were analysed. Convergence was assessed based on region of interest (ROI) analysis of activity concentration within the rods and uniform region. All analyses were performed with PMOD software (PMOD Technologies Ltd., Switzerland).Results: The overall sensitivities for the entire FOV were 2.79%±0.01% and 3.21%±0.01% for 68Ga and 18F, respectively. The net true coincidences with dead-time correction were linear for ≤10MBq (68Ga, R2 = 0.9999) and ≤11.5MBq (18F, R2 = 0.9999). Above these activities, system performed an overcorrection for dead-time effects. The algorithm converged after 35 iterations for both 68Ga and 18F. The recovery coefficients for the 5, 4, 3 and 2mm rods with an activity concentration of 110kBq/ml were 0.50±0.13, 0.41 ±0.09, 0.25±0.06, 0.24±0.04 for 68Ga and 0.80±0.25, 0.72 ±0.21, 0.56±0.20, 0.34±0.10 for 18F, respectively.Conclusion: The Albira pre-clinical PET system has an acceptable sensitivity range and the system linearity is suitable for the range of activity used for pre-clinical imaging. The next step would be to test the system for additional radionuclides that could be used for pre-clinical imaging.

P004

Comparison of time-of-flight PET-CT results for micro hollow spheres from 31 microliter to 8 milliliter for Fluorine-18, Gallium-68 and Yttrium-90

S. Kerschbaumer[1], L. Hofbauer[2], H. Kvaternik[1], C. Gstettner[1], R. M. Aigner[1]; [1]Medical University, Division of Nuclear Medicine, Graz, AUSTRIA, [2]University of Applied Science, Division of Radiography, Graz, AUSTRIA.

The aim of this study was to examine the positron-range-effect simulating focal nodular lesions based on micro-hollow-spheres for Fluorine-18, Gallium-68, and Yttrium-90. The varied kinetic energy of the emitted positrons influences the reconstruction, the quantitative measurement and the visual impression of the resulting sectional images. The measurement procedure uses a target/background ratio of 10:1 and 30:1. A Jaszczak-phantom-body was equipped with micro-hollow-spheres from 31 microliter (4mm diameter) to 8 milliliter (25mm diameter). The images were acquired on a Siemens Biograph-40mCT PET-CT and reconstructed respecting the CT for attenuation-correction (780mm field-of-view, 120keV, 16mA-effective, 5mm slice-thickness, pitch 1.3). Osem-3D and point-spread-function-recovery (HD-PET) were used with and without time-of-flight (TOF) with matrices 256, 400 and 512 with 3 or 4 iterations and 21 (TOF) and 24 (non-TOF) subsets. The acquisition time was altered between 1min to 10min. The maximum and average activity concentration and the threshold-based volumes were evaluated on a Siemens Syngo MMWP. The blurring contribution for different nuclides is effected by the positron-range-effect due to the different maximum positron energy (Fluorine-18 635keV, Gallium-68 1899keV, Yttrium-90 800keV). The measured volume at high contrast, HD-PET and 256-matrix with a 50% threshold was 0,81 (81%) for the 8ml sphere down to 0,50 for the 2ml sphere within 5% deviation independent from the nuclide. For 125µl the measured volume-ratio for Fluorine, Gallium and Yttrium were 1.28, 0.80 and 0.96 measured. The evaluated volume for a threshold of 10% overestimates the lesion in general. Because of the similar positron-range the factor was in a rage of 1.6 for Fluorine and Yttrium. For Gallium-68, the factor was 1.71 for the 8mm sphere and rose continuously for smaller spheres to 3.18 for 500µl, which correlates with an underestimation of the concentration in smaller spheres. The decay corrected average and maximum concentration is widely independent of the acquisition time, where the maximum value raises slightly due to counting statistics for harder reconstruction kernel, smaller voxels and also for lower contrast. For a specific reconstruction algorithm, the measured volume and concentration is not affected by time-of flight. The HD-PET-algorithm compared to the OSEM-algorithm shows higher concentrations and smaller volumes. Image blurring is nonlinear affected by the acquisition system together with the reconstruction algorithm, the lesion and the patient, the nuclide, and the tracer. While some influences can be corrected, for clinical practice it is crucial to understand the effects and characteristics close the physical limits of quantitative functional PET imaging.

P005

Conflicting measures of uniformity on a Siemens Symbia gamma camera

M. J. Memmott, I. S. Armstrong, K. J. Saint, A. Bradley, R. S. Lawson, H. A. Williams, C. M. Tonge; Central Manchester University Hospitals NHS Foundation Trust, Manchester, UNITED KINGDOM.

Gradual worsening of the uniformity of two Siemens Symbia gamma cameras (one Symbia S and one Symbia T6, installed in 2009) has been observed when using the measurement method as described in IPEM Report 86. This method uses a

point source at 5xFOV and assesses the uniformity by pixel coefficient of variation, corrected for Poisson noise, and has been used throughout the department on a variety of camera systems with consistent results. The manufacturer's recommended procedure, using a 1.0 MBq Tc-99m point source at a distance of approximately 40 cm from the detector and calculating uniformity using the NEMA NU1 standard, has failed to demonstrate similar trends over the same time interval. The closeness of the source in the manufacturer's method requires the application of a curvature correction to the image. This does not apply to the IPEM method. Both gamma cameras have recently had new energy and linearity correction maps generated. Uniformity for each method was assessed before and after new correction map generation, and differences assessed using a Mann-Whitney U test for non-parametric data. The mean (SD) uniformity value using the IPEM method prior to new correction maps for the Symbia S was 1.10 (0.05) % and 1.48 (0.09) % for detector 1 and 2 respectively. Post correction map generation, the mean value was 0.58 (0.04) % and 0.62 (0.05) % for detector 1 and 2 respectively. The difference between uniformity values pre- and post-correction map generation was significantly different, $p < 0.001$. Conversely, for the manufacturer recommended method, the mean (SD) integral uniformity value in the CFOV prior to new correction map generation was 1.75 (0.20) % and 1.66 (0.13) % for detector 1 and 2 respectively. Post correction map generation, the values were measured to be 1.74 (0.13) % and 1.58 (0.06) % respectively. There was no significant difference ($p > 0.30$) for either detector. Results for the Symbia T6 followed a similar trend. Two methods for assessing the uniformity of a Siemens Symbia gamma camera show discrepant results over time and show significantly different responses after generation of new energy and linearity correction maps. Discrepancies between the two methods implemented in this work highlight the importance of independent assessment of gamma camera performance.

P006
A Novel Method for Krypton-81m Intrinsic Uniformity Measurement

H. A. Williams, M. J. Memmott, R. S. Lawson; Nuclear Medicine, Manchester, UNITED KINGDOM.

Background: Gamma camera behaviour varies with the energy of the detected photons. Therefore, uniformity assessments and corrections derived using Tc-99m (140keV photons) may not necessarily be applicable at the higher gamma emission energy of Kr-81m (190keV), widely used for lung ventilation imaging. Kr-81m SPECT is particularly sensitive to minor uniformity variations. The rise of V/Q SPECT heightens the need to evaluate uniformity with Kr-81m, although this is challenging due to its short half-life and gaseous nature. We have designed a simple phantom to provide a point-like source for Kr-81m intrinsic uniformity measurement. Methods: A balloon was connected to a commercial Rb-81/Kr-81m generator, with reference activity 300 MBq at 12:00 CET, housed in the shielded control room adjacent to a GE Optima NM/CT 640 gamma camera, with an exhaust tube feeding into a second, adjacent shielded gamma camera room. The generator and tubing were shielded using lead bricks and pots modified for the purpose. The balloon reached an average diameter of 2cm, and was positioned more than 2 metres (~5 gamma camera fields of view) from the uncollimated detector surface, and standard 15 Mct test image acquired. For comparison, a 30 MBq Tc-99m point source (0.1ml in an LP4 tube) was positioned at the same location and another 15 Mct test image acquired. The average count-rate per head was noted. Results: The Kr-81m balloon source resulted in a average count rate of 16.1 kcps, allowing the test image to be acquired in 15.5 minutes. The Tc-99m point source resulted in a count rate of 29.8 kcps, allowing a uniformity test image to be acquired in 8.6 minutes. Image uniformity for Kr-81m was found to be acceptable and comparable with that for Tc-99m, although a slight gradient was seen across both images which infers source positioning requires further optimisation. Conclusion: The phantom which we have developed has potential to provide a quick and simple means of collecting Kr-81m uniformity data. Accurate positioning of the balloon and shielding of the generator and tubing from the uncollimated gamma camera is non-trivial, and will depend on local department layout. A series of measurements are underway to refine source positioning, and assess reproducibility, stability and correlation of Kr-81m uniformity with results for Tc-99m using a Tc-99m source in a similar geometry. Provided that this can be achieved, Kr-81m floods could become a routine QC procedure.

P007
Metrology for ^{89}Zr in the clinic

A. J. Fenwick[1,2], L. Johansson[1], E. Spezi[3,2], W. Evans[4,2], C. Marshall[4,2]; [1]National Physical Laboratory, Teddington, UNITED KINGDOM, [2]Cardiff University School of Medicine, Cardiff, UNITED KINGDOM, [3]Velindre NHS Trust, Cardiff, UNITED KINGDOM, [4]Wales Research & Diagnostic Positron Emission Tomography (PET) Imaging Centre, Cardiff, UNITED KINGDOM.

Despite an increasing number of applications under investigation using the novel PET radionuclide ^{89}Zr, no efforts have so far been made to improve measurements of absolute activity or nuclear data that are required for accurate quantification of the activity in radionuclide calibrators and imaging modalities. The determination of activity by means of a radionuclide calibrators prior to injection is essential to safeguard patients and to enable comparison of results from potential clinical trials. In addition, the determination of activity distribution within patients using quantitative imaging techniques is needed to determine doses received and ensure clinical decisions such as staging of cancer are made correctly. ^{89}Zr decays by electron capture and positron emission to both the ground state and various excited states of ^{89}Y with a half-life of 78.42 (13) hours. The electron capture decay to a metastable state of 14ms at 909 keV presents challenges in the absolute standardisation and appropriate corrections must be considered. In this work, ^{89}Zr was standardised by several liquid scintillation methods including Triple-to-Double Coincidence Ratio (TDCR), CIEMAT/NIST efficiency tracing and 4πß-γ coincidence counting with efficiency extrapolation and results were shown to be in agreement within uncertainties. Secondary standards in the form of calibration factors and dial settings for both NPL maintained and commercially used systems have also been determined for clinically relevant geometries. A new half-life value of 78.366 (78) hours was also determined and shown to be in good agreement with the currently evaluated value. These are the first measurements of the absolute activity of ^{89}Zr and further work in this area is encouraged to give confidence in these results and ensure traceability of this novel and important radionuclide.

P008

Usefulness of Mean Standardized Uptake Value for Liver as a Reference Organ on F-18 FDG PET/CT: Comparison with Standardized Uptake Values Corrected by Various Imaging and Clinical Parameters.

J. Choi[1], S. Lee[1], J. Lee[2]; [1]Soonchunhyang University Hospital Cheonan, Cheonan, KOREA, REPUBLIC OF, [2]Catholic Kwandong University International St. Mary's Hospital, Incheon Metropolitan City, KOREA, REPUBLIC OF.

Introduction/purpose: The use of liver as a reference organ for extrahepatic fluorodeoxyglucose (FDG) uptake on F-18 FDG positron emission tomographic/computed tomographic (PET/CT) scan is well known. Previous studies about relations between hepatic FDG uptake and various parameters including hepatic fat and blood glucose have been contradictory. The aim of the study is to assess the valid standardized uptake values for liver as a comparator for extrahepatic FDG uptake on F-18 FDG PET/CT scan. Materials and Methods: Consecutive F-18 FDG PET/CT scan obtained in 186 healthy subjects from October 2012 to November 2014, were retrospectively reviewed. Mean standard uptake value (SUVmean) and maximum SUV (SUVmax) were measured for liver. Other SUVs were also obtained as followings: (1) SUVLBM; SUVs were normalized by lean body mass, (2) fat-adjusted SUVmean (SUVfat); SUVmean was adjusted for hepatic fat using a formula equating percentage fat to CT density, (3) normalized glucose corrected SUVmax and SUVmean (SUVglc); SUVs were normalized for blood glucose level assuming a normal blood glucose level of 5.55 mmol/L. CT densities (in Hounsfield units) were measured in liver and spleen with identical regions of interest used for the CT and PET examinations. Fatty liver was defined as CT density of liver was less than that of spleen. Patients were divided in 5 groups on the basis of blood glucose. The correlation between hepatic FDG uptake and various clinical factors including glucose, liver function test, total cholesterol, triglyceride, erythrocyte sedimentation rate(ESR), and high sensitive C-reactive protein (hs-CRP) were also assessed. Results: SUVfat and SUVglc of fatty liver were significantly higher than those of non-fatty liver but no difference in SUVmax, SUVmean, or SUVLBM. Liver CT density significantly correlated with SUVmax before and after correcting by normalized glucose, SUVLBM, and SUVfat. Blood glucose significantly correlated positively with liver SUVmax, SUVglc, SUVLBM but not with SUVfat. Liver SUVmax also significantly correlated with BMI, AST, ALT, GGT, and TG. Liver SUVmean correlated neither CT density nor blood glucose. Conclusion: Liver SUVmean correlated neither CT density nor blood glucose while liver SUVmax is influenced by blood glucose and fatty liver. On the basis of these data, liver SUVmean is valid as a comparator for extrahepatic foci of increased FDG uptake in patients with abnormal level of blood glucose or fatty liver.

P009

Evaluation of Qualitative Expressions in Bone Scan Reports

P. Martineau, E. Saidenberg, W. Zeng; The Ottawa Hospital, Ottawa, ON, CANADA.

Background Purpose: The diagnostic report serves as the primary means of communication between nuclear medicine physicians and referring clinicians. Little is known about the variability in clinicians' interpretation of nuclear medicine

physicians' reporting terminology relating diagnostic confidence. Bone scans are the most commonly performed imaging modality in nuclear medicine; however, reporting is poorly standardized because of non-quantitative visual assessment and frequent non-specific findings. Qualitative report text, such as "likely due to" or "suspicious for" may have substantially different meanings when used by different reporting physicians, and can be understood differently by different referring physicians. These differences in interpretation may have important impacts on patient's management. In this study we propose to survey nuclear medicine and referring physicians regarding their assessment of expressions of probability in bone scan reporting. Methods: A review of bone scan reports on Ottawa Hospital cancer patients identified 12 phrases commonly used to communicate likelihood of the presence of skeletal metastases: 'consistent with', 'possible', 'suspicious for', 'cannot rule out', 'suggestive of', 'compatible with', 'in keeping with', 'likely', 'no convincing evidence', 'probably', and 'could be'. A survey regarding qualitative expressions of diagnostic confidence in bone scan reporting was used to investigate referring and reporting physicians' interpretations of these phrases commonly used in bone scintigraphy reports. The survey asked respondents to indicate the probability of disease presence implied by each of the 12 expressions on a numerical scale divided into 0.05 wide bands centred from 0.0 to 1.0 with 0.0 indicating that the condition is definitely not present and 1.0 indicating complete certainty of disease presence.Results: The results of this survey show that there exists substantial heterogeneity in the perceived meaning of standard phrases amongst both referring and reporting physicians. We believe that the results of this study may help inform the process of standardization of bone scan report findings among nuclear medicine physicians.

P010

Semi-quantitative Evaluation of Image Quality in Low Dose 18F FDG PET/CT

S. C. Kapur, Arvind K Sinha,VP Sajjith,Donald Teh and Vijay Sharma; National University Hospital, Singapore, SINGAPORE.

Aim: Quantitative evaluation of tumor metabolism by SUV is increasingly used for evaluation of therapy response of a chemotherapy or radiation treatment. In view of clinical relevance of accuracy and reproducibility of SUV max, SUV peak in PET/CT imaging, it is important to look into these variables at low dose 18 F FDG / CT protocol. This study will evaluate 18 F FDG uptakes in liver, thigh and shoulder and correlate with parameters related to PET/CT image quality. Method and Material: Cumulative radiation dose measurements were made in 150 patients who underwent whole body PET/CT examination with a low dose CT protocol and an average 18F dose of (3.51+0.8MBq/kg), ensuring optimal image quality interpretable by physician. It was optimized by quantitative measurement of SUV max / SD, SUV peak and SNR in PET and CT images of the liver, shoulder and thigh in cases with nearly same BMI and normal blood glucose. Only patients with no observed cancerous lesions were chosen. A spheroid region of interest (ROI) was placed over five selected areas of liver parenchyma in orthogonal plane. The coefficient of variation (CV) for SUV max and SNR was measured in the liver. The Image quality was evaluated by two nuclear medicine physicians in a 5 point Likert Scale Score.- Result and Discussion: This study showed substantial variations in both SUV peak and SUV max for 18F FDG distribution in liver, thigh and shoulder. The image quality at baseline was compared with dose adjusted conditions. Secondly, as a measure of image quality, we evaluated only SUV max , SUV peak and SNR in above organs and SD of the pixel values inside the ROI was used for image noise. It was noted that SUV max was uniformly distributed in the liver, shoulder and thigh in the same scale as SUV peak. The uptake ratio between shoulder and liver, thigh and liver were within same narrow range. The image quality evaluated by the physicians had a score of 4.5/5.0. Patient-specific factors influenced the accuracy and reproducibility of SUV max and SUV peak. The scan quality and diagnostic accuracy was not affected, inspite of reduction in 18F FDG dose and low dose CT parameters. The average whole body effective dose was 9.81+ 2.8mSv, which is reasonable as compared to published data.

Shielding gamma-rays from nuclear medicine rooms: Monte Carlo simulations of ceiling scatter in the diagnostic and therapeutic use of ^{99m}Tc, ^{131}I and ^{18}F

R. S. Schnerr[1], A. de Jong[2], C. R. L. P. Jeukens[1], G. Landry[3], R. Wierts[1]; [1]Maastricht UMC+, Maastricht, NETHERLANDS, [2]Amphia, Breda, NETHERLANDS, [3]LMU, München, GERMANY.

Aim: In the design of diagnostic and therapeutic treatment rooms for Nuclear Medicine, an important consideration is the shielding required for blocking the ionizing radiation from the radioactive isotopes. The primary radiation, possibly with build-up correction, can be calculated analytically. However, little data is available to estimate the radiation dose contribution of ionizing radiation that travels over the (lead) shielding in the wall and scatters of the ceiling; so-called skyshine. We aim to determine the contribution of this skyshine to the radiation dose received by people outside Nuclear Medicine rooms. Materials and Methods: Monte-Carlo simulations were performed with Gate/Géant for different heights of the lead shielding in the wall, and different ceiling heights. A point source of Tc-99m (141keV), I-131 (365keV) or F-18 (511keV) was placed free in air, 1m above the floor, 3m from the wall. We used lead shielding of 2mm (Tc-99m) and 8mm (I-131 and F-18). In total 165 simulations were run; for each isotopes we varied the shielding height (1.8-5.0m) and ceiling height (3.0-5.0m). These simulations allow us to compare the contribution of the direct radiation (through the shielding), and skyshine (over the shielding). Results: We find that the skyshine contribution to the total radiation dose varies greatly (from <2% to ~100%), and strongly depends on photon energy. For low photon energies (e.g. Tc-99m) skyshine is often a dominant factor. For higher photon energies (e.g. F-18), shielding of the primary radiation is typically the most important concern.Conclusion: We have performed simulations that allow an estimation of the contribution of skyshine to the radiation dose outside a room, based on room use (occupancy, total radioactivity used for treatment), ceiling- and shielding height and the isotope used. For lower photon energies (e.g. Tc-99m) this can be a major contribution, which, if neglected, can result in insufficiently shielded rooms. This research will allow for safer and better optimized shielding designs in Nuclear Medicine departments , as the contribution of scattered radiation from the ceiling can be properly accounted for.

P012

Measurement of radioactivity in breast milk following maternal administration of ^{111}Indium-Pentetreotide

R. Bidder, C. Humphreys, S. Evans, A. Smakovs, P. Ali; ABMU Health Board, Swansea, UNITED KINGDOM.

Introduction and Aim: Radiopharmaceuticals administered to breast feeding patients may excrete into breast milk. The purpose of this study was to measure the radioactivity concentration of ^{111}Indium-Pentetreotide in breast milk and to estimate the potential effective dose to a breast feeding preterm infant. A breast feeding patient with a carcinoid tumour of the lung was referred for an ^{111}Indium-Pentetreotide investigation to assess disease extent. We report the results of measurements made on breast milk samples following ^{111}Indium-Pentetreotide administration. Methods: 101.6MBq ^{111}Indium-Pentetreotide was administered intravenously. Breast milk samples were collected on the day of ^{111}Indium-Pentetreotide administration and on days 1, 4, 5, 6, 7 and 8 days post-administration. 3ml aliquots were assayed using a 10 well automatic gamma counter (Perkin Elmer 2470 Wizard^2). Prior to counting, the responses of the 10 detectors were normalised using a standard sample of ^{111}Indium. Activity concentrations (Bq/ml) were corrected for decay between measurement and the time at which the breast milk sample was taken. The potential effective dose to our preterm infant was estimated by adjusting the ICRP value for effective dose per unit activity (mSv/MBq) by the ratio of the standard adult body weight (70kg) to the infants' body weight. Results and Discussion: Planar imaging taken at 24hrs post-injection showed that the ^{111}Indium-Pentetreotide was taken up by the carcinoid tumour of the left lung and there was increased activity within both breasts. The activity concentration in the samples measured 348Bq/ml and 3Bq/ml on day 1 and day 8 respectively. Assuming an ingestion of 180ml/kg/day of breast milk, the total potential effective dose to the preterm infant from breast milk ingestion would be 0.529mSv in the first 8 days. Three published articles have reported the level of ^{111}Indium in breast milk following intravenous administration of ^{111}Indium-labelled white cells and ^{111}Indium-Pentetreotide respectively. The range in the activity concentration (per administered activity (MBq)) in the first 24hours was 0.09-0.31Bq/ml for the ^{111}Indium-labelled white cells and 0.01-0.02Bq/ml for the ^{111}Indium-Pentetreotide. Our range was 2.03-3.42Bq/ml per administered activity (MBq). Our results are much higher than these previous studies. This difference may be related to several factors including chemical form, low numbers of patients involved in the study and the difference in breast milk intake.

P013

Patient Increase Doses From Hybrid Spect-Ct: Evaluation In Common Clinical Practice

T. Ben Ghachem, A. Mhiri; M. Ghezaiel; I. Slim; M. F. Ben Slimène; Nuclear Medicine department; Salah Azaiez Institute, Tunis, TUNISIA.

Introduction: The Single-photon emission tomography combined with computed tomography (SPECT-CT) is a hybrid imaging technique that integrates functional and anatomical data. It is a valuable complement to conventional scintigraphy. With these hybrid devices widely used, patient irradiation is not only related to the administered radiopharmaceuticals, but also to the CT component. That is why supporting physician and patient awareness in additional dosimetry is necessary.Purpose: The aim of this work is to estimate patient doses from hybrid single-photon emission computed tomography (SPECT) and computed tomography (CT) procedures.Methods: The study involved a dual-headed SPECT unit with an integrated 2-slice CT scanner (Symbia T E-Cam, Siemens Medical Systems, Erlangen, Germany) in the ISA (Salah Azaiez Institute) cancer center. Effective dose was estimated for about 146 patients. Data from 168 scans of common nuclear medicine procedures (123I-MIBG, 99mTc-MIBI parathyroid, 111 Inoctreotide,131I post therapy scan, 67 Gallium and 99mTc-MDP bone scan) were presented in this study. The CT parameters used were: tube current of 30 - 90 mAs, slice thickness of 3-5 mm, and tube voltage of 110-130 kV. For each patient the CT was acquired immediately after SPECT; the patient being kept in the same position to minimize offsets due to movement and allow proper registration on fused imaging.Results: One hundred and forty six consecutive patients and 168 SPECT/CT examinations were involved in this study. The average age of patients was 56 years (27-83), the sex ratio was 0.53. The total effective dose received by each patient for SPECT-CT examination was estimated in accordance with the recommendations of the ICRP 53 and 80.The average effective dose have ranged according to type of the exam: 1927,1 mSv for 131I-post therapeutic scans, 7,65 mSv for bone scans and 5.42 mSv for 123I-MIBG scans, and the anatomical region explored: 0.32 for Head and neck region and 4.78 for pelvis. The percentage increase of effective dose by the inclusion of the CT was about 125% for 123I-MIBG scans, 83 % for bone scans, whereas it was negligible in case of treatment with 131I (0.15%).Conclusion: In our study, the increased risk induced by the additional CT with low dose settings in line with SPECT examination, is not significant and does not exceed 0.026%. By weighing the diagnostic value of SPECT/CT examination with that of a stand-alone SPECT examination dosimetric incremental cost is justified because of its direct clinical benefit conveyed to the patient.

P014

A Different Methodology Concept For Measurements And Release Criteria In Thyroid Therapy Procedures

V. R. Mc Cready[1], M. PAPHITI[1], G. S. LIMOURIS[2]; [1]Nuclear Medicine Dept, Royal Sussex County Hosp, Brighton, UNITED KINGDOM, [2]"Aretaieion" Hospital, Athens University Medical Faculty, Athens,, GREECE.

Aim: Patients treated with I -131, are potentially a significant source of radiation hazard to their family members and public. It is aimed, by the present, to evaluate the hospital release parameters of these patients by employing a different (from the commonly adopted) methodology. Methods: Thirty five post-operative thyroid-cancer patients were included in the study and divided into two groups: Group A included patients with metastatic thyroid disease and Group B pts with no metastases. For both groups the range of administered I-131 activity was 2220-5550 MBq and dose rate levels were measured according to a 4-day basis program. Each group employed a different methodology of measurements: For those cases with metastatic disease, the exposure rate was carried out at the surface of the body, just under the mattresses at the side of the main metastases, whereas, in group B measurements were performed at a distance of 1 meter from them, in upright position. By employing the "inverse square law method" for the A group measurements, the results were in concordance with those of group B, and hence a reliable comparison could be obtained. Dose rates were plotted as a function of time and fitted using a bi-exponential model, so as to derive the teff. Since the first post uptake hours are crucial, the teff-fast part and the teff-slow one, have been tabulated. Additionally, the "retained activity" and the "isolation time" have been calculated, according to the specific data of each patient. Results: Both methods showed a difference of 0.6% between them. The variability of "isolation times" among patients indicates a strong relationship of teff on biological half-life and shows no relationship to the administered activity. In addition, the teff-fast ranges from 1 up to 11 hours and in order to avoid a possible radiation risk, thorough care of consequent measurements should be applied. Conclusion: Measurements performed at the surface of the body are reliable and suitable for metastatic disease cases, whereas for non-metastatic ones, thyroid is considered as point source and measurements should be applied at a distance of 1 meter from patient, in standing position. According to our experience, in order to ensure that the treated patient will not expose any individual or the environment to levels greater that the dose limit, a strict dose rate of < 10 μSv/hr at 1 meter and a retained activity <200 MBq should be adopted and established by the authorities.

P015

Hand Phantoms for Optimization of Radiation Protection of Nuclear Medicine Personnel

M. Fulop[1], J. Hudzietzová[2], J. Sabol[3], P. Ragan[4], P. Povinec[5]; [1]Slovak Medical University, Bratislava, SLOVAKIA, [2]Faculty of Biomedical Engineering of CTU, Kladno, CZECH REPUBLIC, [3]Faculty of Safetz management of PACR, Prague, CZECH REPUBLIC, [4]Slovak Centre of Scientific and Technical Information, Bratislava, SLOVAKIA, [5]Nuclear Medicine Clinic BIONT, Bratislava, SLOVAKIA.

AimWhen handling the radiopharmaceuticals, the skin exposure of hands is assessed based on results of routine monitoring using a ring dosimeter. However, the position of the ring dosimeter often does not correspond with the location where the exposure reaches its maximum. It is therefore necessary to determine the relationship between the response of the ring dosimeter reading in terms of the personal dose equivalent H_p (0,07) and the skin dose equivalent at the location with the maximum exposure $H_{p,max}$ (0,07). This relationship can be determined by using hand phantoms simulating specified effects of operations with radiopharmaceuticals which significantly contribute to hand exposure.**Materials and methods**-The position of $H_{p,max}$ (0,07) on hands is determined by mapping of the skin dose equivalent due to gammas and positrons using thermoluminescent dosimeters (TLDs) of type MCP-Ns placed at 11 locations on the surface of hands of workers handling the radiopharmaceuticals. The effects of radiopharmaceutical handling that significantly contribute to the hand exposure have been specified by deconvolution of integral dose equivalent map across all single operations performed during the FDG preparation and administration.The five single procedures that contributed to the dominant values $H_{p,max}$(0,07) during the preparation and administration of FDG to patients have been selected: the application by a shielded and unshielded syringe, hand holding a vial with forceps, holding a container, and hand holding an infusion tube. Physical, voxel and mathematical hand phantoms for all 5 selected operations were constructed.**Results and conclusion**The use of hand phantoms reduces personnel constraints during dose equivalent H_p(0,07) mapping on their hands. Measurement of the dose equivalent distribution for the physical, voxel and mathematical hand phantom proved good agreement with uncertainty lower than 20%. The relationship between the ring dosimeter response and the results of skin dose equivalent monitored at specific locations can be assessed by means of hand phantoms, which simulate single acts that significantly contribute to $H_{p,\ max}$ (0,07). By comparing the physical, mathematical and voxel phantoms hand, it was demonstrated the significance of physical phantoms for the determination of relationship of the ring dosimeters response and $H_{p,max}$(0,07). The results have shown advantages of the use of mathematical phantoms for optimization of radiation protection in nuclear medicine departments.Acknowledgements: This work has been carried out and support by the projects SGS15/114/OHK4/1T/17 and APVV-0241-011.

P016

Estimation of likely Radium-223 releases into the environment from filtration based sewage systems.

D. G. Morgan, A. Hallam; Oxford University Hospitals NHS Trust, OXFORD, UNITED KINGDOM.

This work developed a calculation method for estimating the activity of ^{223}Radium Chloride in a filtration based sewage system, and the likely activity that may be released into the environment from these systems. A patient was referred to our hospital for 6 treatments of ^{223}Ra Chloride as a treatment for bone metastases (from castration resistant prostate cancer). The treatment schedule was monthly injections of 3.5 MBq of ^{223}Ra. The patient had a sewage filtration system at their property with waste water leaving the system and flowing into a network of pipes under the garden of the property, where the waste water disperses into the soil. Our calculations modelled the activity entering and leaving the system during the scheduled treatments and for 3 months after. The activity entering the system was by direct excretion from the patient, in faecal matter, during the first 7 days after intravenous administration. The calculations showed that for an administered activity of 3.5 MBq (for a typical patient weighing 70 kg), the maximum concentration within the sewage tank of 0.33 kBq/l. After calculating the rate that the radioactivity enters and leaves the system per day during the week after administration, it was estimated that the waste removed from the system would lead to a maximum activity of 0.9 MBq in the soil in the patients' garden. We modelled the activity dispersed in the soil and estimated that the concentration of activity in the soil is of the order of 0.6 kBq/l. The conclusion from this calculation model is that due to the relatively long physical half-life, moderate activities of ^{223}Ra may be released into the environment from filtration based sewage systems. This will require consideration of patients' home circumstances, and specific advice must be given to ensure safety of members of the public and the patient's family, particularly if food is consumed from garden produce.

Preclinical small animal PET/MRI for radiopharmaceutical dosimetry

M. Kranz[1], B. Sattler[2], M. Patt[2], W. Deuther-Conrad[1], S. Fischer[1], R. Smits[3], A. Hoepping[3], O. Sabri[2], P. Brust[1]; [1]Helmholz-Zentrum Dresden-Rossendorf, Institute of

Radiopharmaceutical Cancer Research, Leipzig, GERMANY, [2]Dept. Nuclear Medicine, University Hospital Leipzig, Leipzig, GERMANY, [3]ABX advanced biochemical compounds, Radeberg, GERMANY.

Aim:To assess the radiation risk after injection of new PET radiotracers small animal PET/MRI provides the essential whole body biodistribution data for image based dosimetry (ibD). In this study, we investigate ((S)-(-)# and (R)-(+)##-[18F]fluspidine, a PET radioligand for neuroimaging of σ1 receptors in mice. Organ doses (OD) and the effective dose (ED) were determined using PET/MR ibD to assess the radiation risk to humans. The results will be compared to those previously acquired for (-)-*and (+)-** [18F]flubatine, to proof the concept of small animal PET/MRI for incorporation dosimetry to assess the radiation exposure to humans by radiopharmaceuticals.Materials and methods: Six female CD1 mice (weight: 30.9±1.3 g) were injected i.v. with 13.2 ±3.0 MBq (#, n=3) or 12.6±1.4 MBq (##, n=3), respectively. A dynamic 2 h animal PET/MRI protocol was performed (MEDISO nanoScan®, Hungary). All relevant organs were defined by volumes of interest. Time- and mass-scales were adapted to the human anatomy; exponential curves were fitted to the time-activity-data (%ID/organ). The ODs were computed using the adult male model with OLINDA and the ED using tissue weighting factors (ICRP103). The results were compared to previously acquired data of post mortem biodistribution (PMB) studies in mice for (-)-[18F]flubatine (n=27, ∅28.2 g) and [18F]fluspidine (n=28#/n=22##, ∅29.6 g).Results:The excreting organs (kidneys, liver and urinary bladder) received the highest ODs. Subsequently, these organs provide the largest contribution to the ED. The overall radiation risk to humans based on animal biodistribution data acquired with ibD would be 12.9# and 14.0## as compared to 16.7#; 18.4## based on PMB. Comparable results were estimated for [18F]flubatine: 12.5*(PMB), 12.1**(ibD). All conversion factors in μSv/MBq.Conclusion: ibD of [18F]fluspidine reveals significant differences between the two enantiomers. Both in ibD and PMB the tracer with higher affinity and slower kinetics (##) causes a higher radiation exposure than its enantiomeric counterpart (#). Furthermore, the ibD shows lower ED values compared to the PMB due to the intrinsic methodological differences. Small animal ibB is feasible and its reliability needs to be further investigated and confirmed.

P018

Beta+ emitters: workers absorbed doses

G. Tosi[1], F. Provenzano[1], G. Testanera[1], A. Chiti[2]; [1]Istituto Clinico Humanitas, Rozzano, ITALY, [2]Humanitas University, Milano, ITALY.

Aim of this study was to measure and analyze absorbed doses for different workers operating in a nuclear medicine department starting from patient administered activity for PET examinations. In our department, radiopharmacists are in charge of synthesis and quality control of radiopharmaceuticals; nurses are in charge of collecting histories, preparing patients and administering radiopharmaceuticals; technicians are in charge of position patients, acquiring images and discharging patients. Radiation therapy technicians are involved when PET-CT is used for radiation treatment planning, where they help in positioning the patients.Material and MethodWe collected data for 3 beta+ emitters: 11C, 18F and 68Ga and we registered administered activity for 50 patients per radioisotope.For absorbed dose measurements we used an electronic dosimeters (Thermo EPD mk2) that measures equivalent doses in term of Hp(10) and Hp(0.07) and has an energy range between 15 keV and 10 MeV.ResultTable below shows data of mean administered activity for different radioisotopes.RadioisotopeMean administered activity (MBq)11C 332.618F 349.468Ga 129.2In the second table data of equivalent doses per unit of activity are shown (nSv/MBq).11C 18F 68GaHp(10)Nuclear medicine technician 2.4 6 5.8Radiotherapy technician / 5.4 /Nurse / 8.6 / Radiopharmacists 9.6 15.5 73.5Hp(0.07)Nuclear medicine technician 2.3 6.3 9.7Radiotherapy technician / 5.7 /Nurse / 5.7 /Radiopharmacists 10.819.5 439.6ConclusionDosimetric data shows that higher doses are absorbed from radiopharmacists, expecially for 68Ga manually synthesis. Moreover, for all workers, measured doses give a confortable result from radioprotection point of view as bring annual absorbed doses within law limits.

P019

Radiation protection in a veterinary nuclear medicine facility.

C. Pettinato[1], D. De Zani[2], M. Longo[2], G. Ravasio[2], M. Di Giancamillo[2], D. Zani[2]; [1]Medical Physics Unit, Bologna, ITALY, [2]DIVET, University of Milano, Milano, ITALY.

Nuclear Medicine is becoming an important imaging modality in veterinary medicine. The setup of a Veterinary Nuclear Medicine facility is quite simple but requires specific attention to radiation protection of staff and environment. The aim of this work was to describe the radiation protection issues related to a nuclear medicine facility in a veterinary hospital.The nuclear medicine facility is located in a veterinary hospital inside the Radiology Unit. A dual headed gammacamera has been refurbished as follow: one detector head was removed from the gantry and attached on a pensile on the room ceiling, the second detector head was left on the gantry and used as a single headed gammacamera. The pensile camera is used for

big animals standing in front of the detector (primarly horses), while the single head camera is used as a conventional planar and SPECT system for small animals (dogs, cats, felines, rabbits and pigs). An hot room is used for radiopharmaceutical labeling.The floor under the pensile area is equipped with a grid able to collect urine from the animals. Ionization chambers and contaminameters are used to detect surface contamination.From a radiation protection point of view there are the following majors concerns:1) Activity injected to horses is about 6-7 GBq/animal;2) Urine produced by horses can seriously contaminate surfaces and staff members;3) Horses are usually sedated but need the care of staff people that use to stay very close to the animals during scans (bone scintigraphy: 2 hours/scan);4) Small animals need general anesthesia and continuous monitoring during the scans;Staff members, usually veterinary physicians, use to wear lead aprons during scans and their personal monitoring is performed using TLD detectors for whole body and extremity dosimetry.Mobile barriers are used to monitor small animals under anesthesia during all scans.The major risks are related to horses care because of the high radiation exposure rate that they emit. Actually we measured about 25 microGy/hour, 20 microGy/hour and 18 microGy/hour respectively at one meter from the head, the thorax and the animal abdomen. A person standing very close to the animal, holding its head could receive more than 200 microGy per scan.A veterinary nuclear medicine facility is feasible and major concerns in terms of radiation protection are related to irradiation but also to possible contamination. Workers have to be very well trained on radiation protection issues.

P020

Recommended Administered Activity for Ga-68 labelled peptides in Pediatric Nuclear Medicine

J. S. Machado, **Jr**., S. Beykan, M. Lassmann; Department of Nuclear Medicine, University of Würzburg, Würzburg, GERMANY.

Aim: The aim of this study is to suggest values for calculating administered activities for Ga-68 labelled peptides based on the weight-independent effective dose model proposed by the EANM Pediatric Dosage Card for application in pediatric nuclear medicine. Methods: Time-integrated activity coefficients ("residence time") for Ga-68-DOTATATE and Ga-68-DOTATOC were taken from Sandström et al. (JNM 2013), for Ga-68-DOTATOC and Ga-68-Pentixafor from Hartmann et al. (Nuklearmedizin 2009) and Herrmann et al. (JNM 2015), respectively. With these values, the effective doses were calculated by using OLINDA/EXM for the standard series of phantoms (Adult, 15y, 10y, 5y, 1y, newborn). The weight-dependent effective dose coefficients based on these results were rescaled according to the formalism described by Jacobs et al. (EJNMMI 2004), to determine the radiopharmaceutical class of Ga-68 labelled peptides ("multiples" as defined in the EANM dosage card) and to calculate the baseline activities based on an upper limit of the administered activity (185 MBq) for an adult. With the baseline activity value and the corresponding class, the administered activity for Ga-68 peptides related to pediatric diagnostic scans can be calculated by using the EANM Pediatric Dosage Card formalism: A administered [MBq] = Baseline Activity x Multiple. Results: All calculated normalization factors of the effective doses results in the range of -0.9176 and -1.0339. These values suggest that the 68Ga labeled peptides belong to class "B" of radiopharmaceuticals. According to our analysis, the baseline activity for all compounds is 12.8 MBq. As a minimum activity, we recommend 14MBq in analogy to F-18-fluoride. For illustration, we provide the activities and the corresponding weight-dependent effective doses for Ga-68-DOTATATE for a child with 60kg (163MBq, 3.8mSv), 40kg (114MBq, 3.9mSv), 20kg (62MBq, 4.1mSv), 10kg (35MBq, 4.4mSv) and 3kg (13MBq 5.06mSv). Conclusion: For pediatric nuclear medicine with Ga-68 labelled peptides, we suggest determining the activities to administer based on the formalism proposed in this work, so that the effective dose for these procedures can be considered as almost age-independent.

P021

Whole-body Biodistribution, Dosimetry and Metabolite Correction of 11C-palmitate: A PET Tracer for Imaging of Fatty Acid Metabolism

N. L. Christensen, S. Jakobsen, O. L. Munk, S. Nielsen, L. C. Gormsen; Aarhus University Hospital, Aarhus C, DENMARK.

Aim: Positron emission tomography (PET) with fatty acid (FA) or FA analogue tracers has been used extensively to study metabolic processes. For example, 11C-palmitate is used to image FA metabolism in the myocardium, brain and liver, but despite its widespread use in human studies, no published dosimetry, biodistribution or metabolite correction data exist. Dosimetry estimates for 11C-palmitate are based on ICRP 106, where estimates for 11C tracers are listed. These estimates assume that a large proportion of the radiotracer is excreted via urine and that the bladder receives significant radiation resulting in high dosimetry estimates. Typical radiation burden often exceeds 1 mSv per injection in human experimental studies, which limits the use of 11C-palmitate for younger and healthy individuals. However, FAs are rapidly taken up by most tissues, are evenly distributed in the body and not excreted in urine. Hence, the actual radiation burden is probably of a magnitude that enables serial human studies. Our aim

was to correctly calculate 11C-palmitate dosimetry, with a secondary aim to publish population based metabolite correction data. Methods: For dosimetry and biodistribution studies, two pigs and two healthy volunteers underwent a low-dose CT scan and immediately thereafter serial whole-body PET scans (~300 MBq 11C-palmitate) with frame durations 1, 1.5, 2, 2.5 and 3 minutes per bed position. Mean effective dose and standard internal dose exposure in each organ was calculated using OLINDA/EXM software. In the human subjects, a bolus injection of 9,10-3H-palmitate was used to measure the fraction of labelled palmitate incorporated into complex lipids during a typical dynamic study. This fraction was compared to a larger patient cohort, where the fraction of 11C-palmitate in complex lipids was estimated by Sep-Pak. Results: In the pig study, mean effective dose was 3.0 μSv/MBq, with the liver (19.1 μSv/MBq) and kidneys (7.42 μSv/MBq) receiving the highest absorbed doses. In the human study, mean effective dose was 3.2 μSv/MBq, with the liver (27.5 μSv/MBq) and heart wall (10.6 μSv/MBq) receiving the highest absorbed doses. Incorporation of 9,10-3H-palmitate into complex lipids was comparable to estimates obtained by 11C-palmitate with approximate fractions at 10, 20, 30, 40 and 50 minutes reaching 92, 64, 30, 17 and 12%. Conclusion: Mean effective dose of 11C-palmitate was ~3.0 μSv/MBq, resulting in a total dose of ~1 mSv per human study, allowing multiple FA scans. In addition, little variation in free tracer was observed in the human studies allowing population based metabolite correction.

P022

Dosage in Pediatric Nuclear Medicine Diagnostics in Daily Practice

J. S. Machado, S. Beykan, M. Lassmann; Department of Nuclear Medicine, University of Würzburg, Würzburg, GERMANY.

Aim: In pediatric nuclear medicine in daily practice, it is highly recommended to review retrospectively the activities administered to patients for further optimization of the diagnostic procedures. The aim of this study, therefore, was to analyze retrospectively the administered activities and effective doses in pediatric patients undergoing nuclear medicine examinations in our department and compare the results to national and international recommendations. Methods: We collected demographic data and administered activities for the last three years and the two most frequent types of pediatric diagnostic scans in our department (F-18-FDG PET/CT scans and kidney scans with either 99mTc-MAG3 or 99mTc-DMSA). The results were compared to the weight-dependent administered activities calculated from national and international recommendations (EANM 2008 Dosage Card [EANM2008], North America Consensus Guideline [NACG], EANM/SNMMI 2014 Harmonization Document [EANM2014], and German National Recommendation [BfS2012]). In addition, we analyzed the patients' age-weight-dependent resulting effective doses taken from the corresponding ICRP data tables. Results: For F-18-FDG PET/CT scans we performed 88 exams in 44 patients (21 younger than 10 years old). The administered activity ranged from 29MBq to 345MBq; the corresponding effective doses were between 3mSv and 7.1mSv. The mean deviation of the administered activities from the values suggested by EANM2008 was +12.9%, for NACG -33%, for EANM2014 -39%, and for BfS2012 +11.4%. Related to renal scans, there were 242 exams, 216 of 99mTc-MAG3 scans (177 patients) and 26 of 99mTc-DMSA scans (24 patients). A total of 179 patients were younger than 10 years and 129 patients younger than 2 years. The administered activities ranged from 11MBq to 146MBq, the corresponding effective doses between 0.16mSv and 1.62mSv. The mean deviation of the administered activities for 99mTc-MAG3 were +6.3% (EANM2008), -51.4% (NACG), +3.7% (EANM2014), and +16.6% (BfS2012). The corresponding values for 99mTc-DSMA were -24% (EANM2008), -7% (NACG), and +3.2% (EANM2014). No values for 99mTc-DMSA are recommended in BFS2012. Conclusion: The administered activities showed good agreement with EANM2008 and BfS2012, larger differences were observed for NACG and EANM2014 for F-18-FDG PET-CT scans, because of the slightly higher recommended activities. For renal scans (99mTc-MAG3 and 99mTc-DMSA) the results show a good agreement with the EANM recommendations. The effective corresponding effective doses are low. The results of this study show that no change in daily practice is needed.

P023

Automated Dispensing and Injection of ^{18}F-FDG Decreases Personnel Radiation Burden

L. Beels, F. Lavent, D. Nicolaij, O. Gheysens, C. Van de Wiele, A. Maes; AZ Groeninge, Kortrijk, BELGIUM.

Aim: In nuclear medicine departments with a positron emission tomography (PET) system, the personnel doses have increased over the last decade due to an increasing number of PET procedures. In AZ Groeninge, the increasing personnel dose emphasized the need for optimizing the individual workload in order to keep the radiation exposure as low as possible. Therefore, an automated dispensing and injection system was

installed and an additional PET shift was implemented. The aim of our study was to evaluate the personnel whole-body and extremity doses after implementation of the extra shift and automated infusion system in comparison to historical data. *Materials and methods*: A Medrad Intego^{TM} automated dispensing and injection system was used to administer ^{18}F-fluoro-deoxy-glucose (FDG) to the patients. Personnel doses were evaluated using a breast dosimeter provided by SCK-CEN and an extremity dosimeter provided by AIB Vinçotte Controlatom. Both types of dosimeters are thermo luminescence dosimeters (TLD's), that were read out monthly. The radiation dose per PET shift was calculated because not everybody had the same number of PET shifts every month. *Results*: The reference value of the whole-body and extremity dose is respectively 38.48 μSv and 377.48 μSv per PET shift. After implementation of the extra PET shift (in casu 3 PET shifts instead of 2 shifts per day) the extremity dose decreased to 254.85 μSv per PET shift (32.5% reduction), whereas the whole-body dose remained constant (40.90 μSv per PET shift). The second optimisation consisted of using the automated dispensing and injection system. The whole-body dose decreased from 38.48 to 27.27 μSv per PET shift (29.11% reduction) and the extremity dose decreased from 377.48 to 154.66 μSv per PET shift (59.03% reduction). *Conclusion*: In AZ Groeninge, the personnel radiation burden has decreased by adding an extra shift for PET examinations and by using an automated dispensing and injection system. Optimizing radiation burden is an on-going process and further analyses are necessary to keep decreasing the personnel whole-body and extremity dose.

Proposal of correction factors for the assessment of the maximum exposure to hands of workers handling radiopharmaceuticals labelled with F-18: Based on studies in CR and SR

J. Hudzietzova[1], M. Fülöp[2], J. Sabol[3], J. Doležal[4], J. Kubinyi[5], P. Povinec[6], I. Makaiová[7], A. Vondrák[8]; [1]Faculty of Biomedical Engineering, CTU Prague, Kladno, CZECH REPUBLIC, [2]Slovak Medical University, Bratislava, SLOVAKIA, [3]Faculty of Safety Management of PACR, Prague, CZECH REPUBLIC, [4]Department of Nuclear Medicine,University Hospital, Hradec Králové, CZECH REPUBLIC, [5]Institute of Nuclear Medicine of GUH, Prague, CZECH REPUBLIC, [6]Nuclear Medicine Clinic, BIONT, Bratislava, SLOVAKIA, [7]Oncology Clinic of St. Elizabeth, Bratislava, SLOVAKIA, [8]Isotope Centre, Nitra, SLOVAKIA.

Aim: The local exposure of the skin on hands averaged over 1 cm^2 constitutes a limiting factor in handling radiopharmaceuticals. In most cases, the maximum local exposure is at the tip of the index finger. The aim of this paper is to determine the correction factors (CFs) to modify the value of the personal dose equivalent $H_p(0.07)$ measured in places where finger dosimeters are worn (root index, middle or ring finger) in order to assess realistically the maximum local exposure of workers at selected PET nuclear medicine clinics in the Czech Republic (CR) and Slovak Republic (SR).**Materials and methods**: The group under investigation included the workers which were preparing or applying radiopharmaceuticals labeled with F-18 (three PET clinics in CR and SR). The quantity $H_p(0.07)$ was determined based on TLDs where altogether 12 pairs of TLDs (MCP-Ns and MCP-7) on each operator's hands were used. The results were related to the activity manipulated by the worker (about 10 GBq). Up to now, 164 measurements on 27 persons (CR) and 80 measurements on 8 persons (SR), were completed, respectively. The CFs, the ratio of maximum exposure to the result obtained from finger dosimeter monitoring (root of the index finger), were determined for each PET clinic, as well as for individual professional groups. **Results**: Based on measurements using TLDs, the maximum exposure was found on top of index fingers in about 63% of workers in CR and in 47% workers in SR. The CFs were determined taking into account not only procedure (preparation, application) but also technological equipment at the clinic (semiautomatic dispensing stations, semiautomatic applicators). The values of the CFs also differ in various groups in each clinic for right and left hand. In some cases, the CFs reached values up to 13 (CR) and 16 (SR) while average CFs were 3.2 in CR and 2.5 in SR.**Conclusion**: The experimentally obtained values of $H_p(0.07)$ have shown that the maximum local exposure was usually found in the place where finger dosimeters are not routinely worn (the tip of the index finger). Underestimation of local exposure may amount in some cases up to a factor of 13 in CR and factor 16 in SR. Therefore, it is recommended to consider the introduction of appropriate correction factors for various categories of workers who may not all handled radiopharmaceuticals the same way.Acknowledgements: This work was partially supported by the projects SGS15/114/OHK4/1T/17 and APVV-0241-011.

Assessing the effect of the amount of injected 99mTC-MIBI on the calculated cardiac volume in the myocardial Gated-SPECT, A clinical survey

S. Entezarmahdi[1], A. Kamali-asl[1], M. Haghighatafshar[2], F. Gheisari[2], M. Hemmatpour[2], F. Khajerahimi[2]; [1]Radiation Medicine Engineering Department, Shahid Beheshti

University, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Nuclear Medicine Department, Shiraz University of Medical Science, Shiraz, IRAN, ISLAMIC REPUBLIC OF.

In recent years nuclear cardiology has been rapidly extended and so many myocardial scanning perform daily. In this manner the public awareness and public concern with regard to radiation exposure in relation to this popular scanning protocol has been raised in the last decade. Accordingly with the implementation of new imaging techniques and systems, the needed dose per examining could be reduced. In this work we tried to find whether the reduction in injected dose can affect on calculated cardiac volume.Seventy five patients with the known probability of coronary artery disease who was referred to our ward enrolled in this study. To make different amount of radioactive deposited in a same myocardium, we repeated each patients' scan twice after one injection. The second Gated-SPECT scan was performed when the deposited 99mTc in the myocardium decayed up to 30 percent. Assuming that MIBI has not any significant redistribution in this time, the only parameter which has been changed is the amount of radioactivity within the myocardium. In this way we have two different images with different deposited dose in the myocardium from each patient. All the images reconstructed and processed similarly. End diastolic and end systolic volumes (EDV, ESV) was calculated by Corridor-4DM software.With reduction of radioactivity within the myocardium, as the images declare, because of partial volume effect the mid-myocardium points do not change substantially. On the other side the standard deviation of count profile decreases meaningful. Consequently, the calculated cavity volumes increased as the radioactivity decreased in the myocardium. Our results show that, with 30 percentages reduction of radioactivity within the myocardium can lead to up to 39.00 ml growth in calculated EDV (mean difference 2.84 ml, p-value=0.010) and up to 24.00 ml growth in calculated ESV (mean difference 2.35 ml, p-value=0.007).In summary we showed that, reduction in used radioactivity for myocardial perfusion scan with Gated-SPECT, could lead to statistically significant growth in calculated cavity volume both in end diastole and end systole phase.Key Words: Myocardial Perfusion Image, Gated-SPECT, Injected dose, Cavity Volume

Transportation of radioactive material for Nuclear Medicine: risk assessment in the area of Bologna

S. Vichi[1], G. Cicoria[2], D. Pancaldi[2], A. Infantino[1], C. Po[3], D. Mostacci[1], M. Marengo[2]; [1]Montecuccolino Nuclear Engineering Laboratory, Department of Industrial Engineering, University of Bologna, Bologna, ITALY, [2]Medical Physics Department, "S. Orsola-Malpighi" Hospital, Bologna, ITALY, [3]Servizio Sanità Pubblica, Regione Emilia Romagna, ITALY.

IntroductionTransportation of radioactive material is regulated at International level by specific standards and procedures to ensure an adequate level of safety of people and the environment. However, no widely applicable guidelines about emergency procedures in case of accident have been approved and published by international organisms. The aim of this work is to collect statistical information on transportation of radioactive materials in the area of Bologna (Italy) and to evaluate the potential radiological risk for the population and first responders in case of accident; data were used to create a model for risk assessment as a support for the definition of an emergency protocol.**Materials & methods**An investigation of transportation of radioactive materials in the area of Bologna was conducted collecting data on authorized carriers, consignees, itineraries, type of package transported (excepted, type A / B), radioactive content of each package (radionuclide, physical form, activity), population density, vehicle traffic density and accident rate. Risk was assessed using INTERTRAN2 package, a computer code system developed by AMC Konsult AB (Bromma, Svezia) in the scope of an IAEA Coordinated Research Program. An event tree analysis was conducted to identify the most representative cases to be simulated by INTERTRAN2. To take into account the different levels of danger of an accident, severity categories were defined; the probability that an accident belonged to a defined severity category was assessed and, for each severity category, the package response was defined in terms of the release of radioactive material.**Results**More than 200 different scenarios were studied. As an example of a typical situation, we evaluated an accident involving a vehicle carrying 5 packages of ^{123}I (activity per package (a.p.p) 8.91E+08 Bq), 10 packages of ^{131}I (a.p.p. 2.92E+10 Bq), 5 packages of ^{125}I (a.p.p. 9.25E+08 Bq) and 1 package of ^{99}Mo (a.p.p. 2.25E+11 Bq). The evaluated population risk in terms of collective dose was 5.05E-10 person*Sv. On the basis of the studied cases, the average risk in transportation associate with each consignee for the S. Orsola-Malpighi Hospital was evaluated as 3.41E-10 person*Sv.**Conclusions**As a general result, risk assessment analysis of radionuclide sources in the area of Bologna showed a low risk for the population in case of accident. All information collected and results led to the implementation of a database for risk assessment, with reasonable and realistic assumptions. Moreover, this framework can be also applied to different scenarios and environment.

Promotion of measures to counter radiation health concerns using the comic (manga)

k. ohno[1], T. Higashi[2], C. Okuyama[3], Y. Nakamoto[4], K. Endo[1]; [1]Kyoto Collage of Medical Science, Nantan, JAPAN, [2]Shiga Medical Center Research Institute, Moriyama, JAPAN,

[3]Image Communiation Corporation, kyoto, JAPAN, [4]Graduate School of Medicine Kyoto University, kyoto, JAPAN.

[Aim]Since the Fukushima Daiichi Nuclear Power Plant accident, four years have passed. However, Japanese people do not have most of enough opportunity to study the basic information about the radiation effect. Nuclear physicians created informative comic (manga) to promote measures to counter radiation health concerns.[Materials and Methods] All questions and answers were collected related to inquiries from the general public that were posted to reliable websites from March 2011 to November 2012.More than sixty classes and dialogs had been held at eight prefectures from October 2012 to January 2014. All the questions from participants were collected.[Results and Conclusion]The questions could be broadly classified into health effects, food safety and radiation-related knowledge. To put out accurate information about these questions, informative manga were produced, taking ideas from educational activities implemented at junior high school in Fukushima. This comic (manga) will be presented in this meeting. This comic (manga) will be useful to help people think about the issue of radiation effect.

Radiation Protection Recommendations for Releasing Patients Treated with 131I for Thyroid Cancer

E. Mora Ramirez; Caja Costarricense del Seguro Social / Universidad de Costa Rica, San Jose, COSTA RICA.

The Nuclear Medicine Department at the San Juan de Dios Hospital has considered radiation protection guidelines given by the IAEA for releasing patients after 131I treatments for thyroid cancer, in the Safety Report Series No. 63, “Release of patients after radionuclide therapy”, published in 2009. However, IAEA guidelines are based on the administrated activity and it does not take into account bio-kinetics of the 131I into patient body, distance between patients and its relatives, etc. Our goal is to establish patient specific recommendations considering dose limits to relatives and caregivers, also bio-kinetics of thyroid and extra - thyroid compartments, taking into account NUREG-1556, Vol 9, Rev. 2 from USNRC considerations. For 47 patients (female 44), age range from 79 - 20 years old; effective half - life for thyroid and extra - thyroid compartments have been estimated, occupation factor, distance and effective dose have been set. Preliminary results, for average data, showed good agreement with IAEA guidelines for ablation patients in restrictions for children under 2 years old, time off work and sleep apart, however, restrictions for children from 2 to 11 years old and are not similar; on the other hand, for follow-up patients, in our case this means patients with recurrence or metastatic diseases, results are very different from the IAEA guidelines for all restrictions, our results showed that restriction times have to be increased, this means that patients specific bio-kinetics have to be take it into account. Therefore a method to establish patient specific radiation protection recommendations can be applied in a Nuclear Medicine Department taking into account bio-kinetics of 131I.

Standard OSEM vs. Regularized PET Image Reconstruction: Qualitative and Semi-Quantitative Comparison

A. Iagaru, J. Lantos, E. Mittra, C. Levin; Stanford University School of Medicine, STANFORD, CA, UNITED STATES.

Introduction: A PET image reconstruction tool (Q.Clear®) has been recently introduced that allows more iterations of the raw PET data than the standard OSEM image reconstruction, to enable contrast recovery without amplifying noise. Here we qualitatively and semi-quantitatively compared Q.Clear® with the standard OSEM image reconstruction available on our clinical PET/CT scanners (GE Discovery 600 and 690) using patient data. Materials and methods: PET datasets from 30 previously acquired clinical research scans (16 68Ga-DOTA TATE, 11 18F-FPPRGD2, 1 18F-FLT, 2 18F-FSPG) were reconstructed using Q.Clear® (25 iterations with 3 different regularization strength or "beta" values) and compared to standard reconstruction for Discovery 600 (2 iterations and 32 subsets; with PSF modeling) and 690 (2 iterations and 24 subsets; with PSF modeling) scanners. Each of the 4 reconstructions/scan were reviewed blindly by 2 experienced nuclear medicine physicians and scored 1-5 (1 poor, 5 excellent quality). The SUVmax of the smallest lesion detected in each patient was also measured for comparison. The paired Welch t-test was used for statistical analysis. Results: Significant differences ($P < 0.01$) were noted on visual analysis for 2 beta values (350 and 450) vs. OSEM (the mean visual scores were 3.59±0.65, 3.88±0.42, 3.89 ±0.28 and 3.36±0.56 for Q.Clear® with the 3 beta values and the OSEM, respectively). SUVmax values were significantly higher ($P < 0.01$) on Q.Clear® reconstructions, resulting in increased conspicuity for some small lesions. In 2 cases, lesions were only identified on Q.Clear® reconstructions and confirmed on follow-up MRI. Conclusion: Q.Clear® with a higher number of iterations maintains image quality. Visual analysis confirmed that overall image quality is improved and may allow for improved detection of small lesions as compared to the image quality from the standard OSEM algorithm.

How Does Increasing the Matrix Size / Reducing Voxel Volume Impact Quantification in FDG PET? A Detailed Analysis for Optimizing the Clinical Utility of Next Generation Digital PET/CT

K. Binzel[1], J. Zhang[1], B. Zhang[2], Z. Hu[2], P. Bardos[1], M. V. Knopp[1]; [1]The Ohio State University Wexner Medical Center, Columbus, OH, UNITED STATES, [2]Philips Healthcare, Cleveland, OH, UNITED STATES.

The introduction of solid-state PET detectors with improved count rates as well as spatial resolution facilitates the use of a larger reconstruction matrix and smaller voxel volumes. This study analyzes the impact of reduced voxel volumes on lesion quantification in whole body oncologic PET/CT independent of the visual appearance and the impact of iterative reconstruction parameters.Philips Vereos TF 64 PET/CT (Cleveland, OH) listmode data of 15 clinical patients were acquired after average injection of 480 MBq 18F-fluorodeoxyglucose (FDG). Patients were imaged from the skull to mid-thighs with 90 seconds per emission volume. Default image reconstruction used a 4 x 4 x 4 (64) mm3 voxel volume, 144x144 matrix. Additionally, data were reconstructed using a 2 x 2 x 2 (8) mm3 voxel volume, 288x288 matrix, and a 1 x 1 x 1 (1) mm3 voxel volume, 576x576 matrix. Image sets were also reconstructed using different iterative parameters. Using the 4mm images as reference, target lesions as well as physiologic uptake in background tissues were assessed by region of interest SUVmax on each image set by multiple independent readers.Utilization of a larger reconstruction matrix leads to substantially increased SUVmax's in smaller metabolically active tissues. For 8 mm3 voxel images, the average percent difference from default SUVmax was a 16% increase, with a range for target lesions from 0.2% to 48%. For 1 mm3 voxel images, the average percent difference from default SUVmax was an 86% increase, with a range for target lesions from 25% to 186%. There is an observable trend that the increase in SUVmax is most pronounced in smaller or more heterogeneous lesions. This observation concurs with a prior phantom assessment. The quantitative impact of the range of variable number of subsets per iterative reconstruction was minimal. We determined the following to be preferential: 144x144 matrix 3 iterations 15 subsets, 288x288 matrix 3 iterations 13 subsets and 576x576 matrix 3 iterations 11 subsets.Digital PET/CT appears to enable larger matrix size / reduced voxel volume reconstruction that impacts quantification especially in smaller, metabolically active lesions. This observation is consistent with improved recovery coefficients in phantom data. Larger matrix reconstruction appears to be promising in digital PET by reducing partial volume effects and thus not only improving detectability but also quantitative accuracy.

P031

Optimisation of ventilation/perfusion (V/Q) SPECT reconstruction utilising advanced reconstruction methods: a phantom study

M. J. Memmott; Central Manchester University Hospitals NHS Foundation Trust, Manchester, UNITED KINGDOM.

Introduction: Advanced image reconstruction methods implementing resolution recovery (RR) and regularisation (REG) have been exploited in various areas of nuclear medicine with the aims of improving image quality and reducing administered activity and/or acquisition time. This phantom study aimed to investigate their potential use in ventilation/perfusion (V/Q) lung SPECT. Methods: The background volume and spheres of a NEMA image quality phantom were filled with an equal Tc-99m activity concentration, equivalent to clinical ventilation SPECT. After acquisition on a GE Optima 640, using ELEGP collimators, the background activity concentration was increased by a factor of 5 to mimic perfusion SPECT, with the spheres representing mismatched defects. Reduced count SPECT datasets were also simulated via Poisson sampling to give 25 - 100% of the clinical count rate. Attenuation-corrected reconstructions were performed using variants of the GE Evolution Toolkit; implementing ordered-subset expectation-maximisation (OSEM), OSEM with RR and OSEM with RR and REG (currently reserved only for cardiac studies). The contrast for each sphere was derived from the mean voxel count in a spherical volume of interest (VOI) and mean background voxel value from 12 additional spherical VOIs. Background noise was measured using the mean coefficient of variation in background VOIs. The ratio between contrast and background noise (CNR) was calculated for each sphere. The optimal reconstruction parameters were derived through blinded interpretation of a subset of clinical reconstructions by a Consultant Nuclear Medicine Physician. Results: Reconstruction implementing OSEM with RR and REG gave highest CNR in all spheres when compared with OSEM alone, due to the noise limiting effect of regularisation. Reconstruction using OSEM with RR however gave the greater contrast overall. Optimal reconstruction parameters were found to be with 5 iterations and 10 subsets. When compared to the optimal OSEM derived data, equivalent quantitative image quality was achieved when implementing RR and RR with REG using approximately 50% of the acquired data. Conclusions: Image quality of reconstructed data acquired from a phantom mimicking a V/Q SPECT acquisition was found to be enhanced when implementing both RR and RR with REG, giving increased contrast or reduced noise respectively. Half of the clinical count-rate was required to give an equivalent image quality to OSEM, indicating that either acquisition times and/or administered activity have the potential to be reduced in clinical practice when implementing advanced reconstruction methods.

P032

Q. Freeze Software for Respiratory Motion Correction in PET/CT: A Preliminary Investigation with a Respiratory Motion Phantom

G. Havariyoun, D. Ruiz, E. Kalogianni, B. Corcoran, A. Eccles, N. Mulholland, G. Vivian; King's College Hospital, LONDON, UNITED KINGDOM.

Aim: PET/CT imaging of the lung and abdominal region can often lead to apparent increase in tumour volume, underestimation of measured standardized uptake value (SUV), and mismatched PET and CT images due to respiratory motion. GE Healthcare Q.Freeze software uses 100% of the detected events and can perform respiratory phase matching of gated PET and low-dose 4D-CT data to minimize respiratory motion artefacts. This investigation aimed to assess the effectiveness of the Q.Freeze software. **Material and methods**: The GE Discovery 710 PET/CT scanner was used to scan the Quasar® Respiratory Motion Phantom (QRMP) with two in-house constructed inserts. The QRMP inserts consisted of 4ml and 1ml ^{18}F-FDG filled spheres in air and water to model spherical lesions in lung and liver respectively. Scans were performed with a sinusoidal respiratory waveform of 20 breaths per minute (bpm) with 20mm amplitude and a single patient specific respiratory cycle pattern. Varian's Real-Time Position Management System was used to monitor the phantom's motion. Images acquired when the QRMP was motionless were used as benchmark. For each motion experiment three sets of images were reconstructed; ungated PET (UG-PET), Q.Freeze PET only gated (4D-PET) and finally Q.Freeze PET with cine CT (4D-PET/CT). Images obtained were quantitatively assessed for background variability (BV), sphere volume and SUVs. All analysis was performed on a Hermes® nuclear medicine workstation. **Results**: UG-PET images had the largest increase in volume and reduction in SUV when compared to benchmark in all images. 4D-PET and 4D-PET/CT improved accuracy by increasing SUV_{max} by a mean of 33% and 31% and decreasing volume by a mean of 216% and 211% when compared to UG-PET respectively. The improvement was greater in all cases for 4D-PET compared to 4D-PET/CT, apart from in air where 4D-PET/CT showed marginal enhancement by increasing SUV_{max} by 5% and decreasing volume by 14% compared to UG-PET. BV was largest for the 4D-PET/CT in all acquired images. **Conclusion**: Preliminary results clearly indicate that Q.Freeze largely improves SUV and volume figures when compared to UG-PET images. These results do not justify the extra radiation exposure to patients if 4D PET/CT was performed. The next step of this study will involve the construction of an insert that will replicate lesions on the liver-lung boundary.

P033

Reproducibility of quantification in F-18 FDG PET clinical application varying protocols parameters and lesions dimension

A. Zorz[1], E. De Ponti[1], L. Guerra[2], S. Morzenti[1], M. Cuzzocrea[3], C. Crivellaro[3], A. Crespi[1], M. Arosio[2], C. Landoni[3]; [1]Medical Physics, A.O. San Gerardo, Monza, ITALY, [2]Nuclear Medicine, A.O. San Gerardo, Monza, ITALY, [3]Nuclear Medicine, University of Milano Bicocca, Milano, ITALY.

Aim: Measurements of tumor metabolism is used to evaluate response to treatments using quantitative parameters as SUVmax and SUVpeak. However, they are strongly influenced by various technical features of the the scanner system, injected activity, acquisition time, reconstruction parameters and lesion's characteristics as dimension. Aim of the study was to investigate SUV variability between different size lesions and reconstructed images with a newest high sensitivity PET/CT scanner (Discovery IQ from GE Helthcare) equipped with the new Q-Clear regularised reconstruction algorithm. Q-Clear algorithm incorporates a factor (i.e. Beta parameter) able to modulate the noise allowing the algorithm to reach the full convergence of the data without excessively increasing the noise, as usually found with standard OSEM reconstruction (VPHD). Material and Methods: GE Discovery IQ scanner was used for acquisition of list data and regularised reconstruction (Q.Clear) was used with different regularization beta parameter (from 500 to 200 units). SUVmax and SUVpeak of both Q-Clear and VPHD were calculated and compared in 60 lesions. Lesions were stratified according to injected activity (standard dose 3.7 or half dose 1.8 MBq/kg) and lesion dimension (range 6-50mm, cut-off 15mm). SUVmax and SUVpeak variability was analysed as a function of the acquisition time (from 45s to 2min/FOV for standard dose and from 2min to 4min/FOV for half dose) and different beta parameters. Patients' height, weight and BMI were also balanced between compared datasets. Results: SUVmax and SUVpeak showed a complete overlap between measurements with decreasing acquisition time/FOV in both VPHD and Q-Clear reconstructions (maximum difference below 5% and linear regression model $p<0.0001$). Quantification was not affected by time of acquisition/FOV both in small and larger lesions, whereas SUVmax and SUVpeak were significantly influenced by variation of beta values and differences were higher in small lesions (37% and 15% for SUVmax and SUV peak, respectively) with respect to larger ones (14% and 6%). A maximum difference of 38.5% between VPHD and Q-Clear was measured for SUVmax quantification in smaller lesions group. Conclusion: Our data showed that SUVs were not affected by acquisition time/FOV with this new high sensitivity PET/CT system, both for small and large lesions. According to our results, quantification stability could allow the therapy response assessment with different acquisition time, condition sometime requested by patient compliance or clinical workflow.

P034

Impact of a new Bayesan penalised likelihood reconstruction algorithm on ^{68}Ga-DOTA-TOC PET/CT imaging

M. Scarlattei[1], G. Baldari[1], S. Migliari[1], C. Ghetti[2], C. Cidda[1], G. Serreli[2], L. Ruffini[1]; [1]Nuclear Medicine Dept, University Hospital of Parma, Parma, ITALY, [2]Medical Physics, University Hospital of Parma, Parma, ITALY.

In PET reconstruction standard iterative algorithms have different numbers of iterations, subsets and filters. It is now available a new Bayesian penalised likelihood reconstruction algorithm (QC, GE Healthcare, Milwaukee, USA) that requires only one input the penalisation factor (named beta).Aim of our study was to investigate clinical impact of QC algorithm compared to standard reconstruction approach (VP) in PET/CT study with ^{68}Ga-DOTA-TOC.Nineteen patients (7 men, 12 women; 13-80 years) with known or suspected NETs and tumours other than NETs underwent ^{68}Ga-DOTA-TOC PET/CT. All studies were performed on a Discovery IQ scanner (GE healthcare, Milwaukee, USA). Patients did not receive medical treatment before exam. Main indications for NETs were staging, follow-up and recurrence; for the suspected NETs increased tumor markers, clinical symptoms, and findings in conventional imaging; for non-NETs lesions indication was the SST receptor status for receptor radiotherapy with labeled SST analogues.Whole body PET/CT was performed according to the standard protocol (head-to-mid-thighs) 60 minutes after 68Ga-DOTA-TOC injection (130-220 MBq). Images were processed using QC for a range of different beta values (100-1000) and standard VP reconstruction (2 iterations, 24 subsets, 6.4mm filter).We analyzed images in a qualitative and semiquantitative way. Lesion and liver SUVmax, and liver SUV mean were measured on VP and QC images, using a VOI drawn on the PET transaxial slice presenting the highest uptake value. The maximum diameter of each lesion was measured on transaxial CT images.^{68}Ga-DOTA-TOC PET/CT was positive in 6/19 patients (31.6%). Lesions were visually localized in the meninges, lung, small bowel, lymph nodes, bone and sympathoadrenal system.A lesion-by-lesion analysis was performed and in patients with multiple foci lesion with the highest uptake was assessed. Mean lesion SUVmax was 26.3 and 32.4 in VP and QC images, respectively, Mean liver SUVmax and SUVmean were 11.03 and 11.3, 7.7 and 7.8 in VP and QC images. Mean lesion diameter was 24 mm (9-70). Micrometastases of the bone were not

completely visualized by VP images (1 patient with two bone lesions on QC images and uncertain VP; SUVmax 1.8 and 3.5 in VP and QC images)**Conclusion**: the Bayesian penalised likelihood reconstruction algorithm (QC) achieves a significant increase of SUVmax values measured in the lesions compared to the VP (32.4 vs 26.3) on 68Ga-DOTA-TOC PET/CT images. QC shows higher sensitivity in the detection of bone lesions. This new algorithm is likely to improve global cancer detection, especially for small lesions.

P035

Quantification with the new regularized reconstruction algorithm QClear in 4D and QFreeze acquisition

A. Zorz[1], S. Morzenti[1], L. Guerra[2], M. Cuzzocrea[3], E. De Ponti[1], A. Crespi[1], M. Arosio[2], C. Landoni[3]; [1]Medical Physics, A.O. San Gerardo, Monza, ITALY, [2]Nuclear Medicine, A.O. San Gerardo, Monza, ITALY, [3]Nuclear Medicine, University of Milano Bicocca, Milano, ITALY.

Aim: The aim of this study is to evaluate how the quantification of lung and hepatic lesions changes when the new regularized reconstruction algorithm QClear in different motion management protocols and 3D standard acquisition is applied. Material and Methods: The latest generation of the Discovery PET/CT family (GE Healthcare - Milwaukee; WI-US) is equipped with the new regularized reconstruction algorithm QClear, an iterative algorithm that performs 25 iterations to reach full convergence. Image noise could be optimized setting the beta parameters according to the data statistics. This preliminary evaluation is performed on 13 patients submitted to a 3D scan of 1.5minutes/FOV with a 9 minutes 4D FOV integrated into the WB scan. Data are acquired in list mode in order to perform different reconstruction: a standard 3D image of 1.5 minutes with beta 350 (WB), a 4D image of 6 phases each of 1.5 minutes with beta 350 (4D-QC350) and a 4D image of 6 phases each of 30 seconds with beta 450 (4D-QC450). These last data are also processed with the QFreeze algorithm, that performs a non rigid coregistration of all the 4D bins to obtain motion corrected static images (QFreeze). Values of SUVmax and SUVmean of 13 lesions are collected. Results: The mean values of SUVmax of WB, 4D-QC350, 4D-QC450 and QFreeze are respectively 7.30, 9.39, 9.41, 7.24. The same values for the SUV mean are 4.44, 5.80, 5.79, 4.68. For the 4D reconstructions, the highest SUV values among all bins are reported. For both parameters, the comparison of QFreeze versus 4D-QC350 is statistically significant ($p<0.0001$ for SUVmax and $p=0.0001$ for SUVmean respectively), while the differences between QFreeze and WB and between 4D-QC350 and 4D-QC450 are not statistically significant. Conclusion: Using the QClear algorithm, the same quantification is obtained both in a standard WB protocol and in a motion management protocol based on a non rigid coregistration (QFreeze). However, 4D protocol permits to measure the highest SUVmax and SUVmean values. Furthermore, no changes in quantification are observed in 4D reconstructions reducing the acquisition time from 9 minutes/bed to 3 minutes/bed and optimizing the beta parameters.

P036

Quantitative SPECT/CT imaging using a commercial software

L. D'Ambrosio[1,2], L. Aloj[1], P. Chiaramida[3], V. Cerciello[2], P. Gaballo[1], A. Prisco[1], S. Lastoria[1]; [1]SC Medicina Nucleare, Istituto Nazionale Tumori Fondazione G. Pascale - IRCCS, Napoli, ITALY, [2]UOSD Fisica Sanitaria, Istituto Nazionale Tumori Fondazione G. Pascale - IRCCS, Napoli, Italy, Napoli, ITALY, [3]GE Healthcare, Rome, ITALY.

Aim Routine SPECT imaging lacks quantitative information. The use of CT attenuation correction and lesion localization based on the fusion of diagnostic CT and SPECT datasets can improve accuracy. This work aims to validate commercially available software (Q.Metrix, GE Healthcare) that provides absolute quantification (SUV) and investigates the feasibility of applying this software in clinical practice. Materials and methods For absolute quantification Q.Metrix needs data of patients, injected activity information and camera sensitivity. This software includes tools for performing reconstruction of SPECT/CT data with attenuation, scatter and collimator depth-dependent three-dimensional resolution recovery correction. Furthermore it includes also segmentation tools both on CT and NM images. All acquisitions were performed using hybrid dual-head SPECT-CT camera (Discovery 670, GE Healthcare). Camera sensitivity was evaluated for Tc99m and I131. Accuracy of activity quantification was performed on a large homogeneous source with addition of attenuating/scattering medium. A NEMA/IEC body phantom was utilized to measure recovery coefficients. Studies of patients undergoing Tc99m MAA lung perfusion scans and I131 in post-therapy scans were analyzed. Results Tc99m (I131) sensitivity factor was 71.4 (26.1) counts/MBq*s using a source in a petri dish and planar acquisitions as recommended by the manufacturer. A simulation utilizing homogeneous phantoms containing activities yielding SUV values of 1 for the two nuclides provided measured SUVmean values of 1.08 for Tc99m and of 0.75 for I131. Recovery coefficient varied from 0.88 (26.5 ml) to 0.27 (1.15 ml) for Tc99m and from 0.53 (26.5 ml) to 0.10 (1, 15 ml) for I131. Preliminary patient studies performed show the feasibility of quantitatively assessing lobar distribution of Tc99mMAA in the lungs and absolute quantitation of lesion uptake in post-therapeutic I131 scans. Conclusions Although inferior in accuracy to PET/CT this method can be applied on

clinical SPECT-CT systems and can yield reproducible results. The possibility of performing absolute quantitation of tracer uptake in Bq/ml opens the way for novel clinical and research applications using single photon labeled radiopharmaceuticals.

P037

Optimization of acquisition time of 68Ga-PSMA-ligand PET/MRI in patients with local and metastatic prostate cancer

S. Lütje[1], S. Blex[2], B. M. Schaarschmidt[3], A. Bockisch[1], T. D. Poeppel[1], A. Wetter[2]; [1]Clinic for Nuclear Medicine, University Hospital Essen, Essen, GERMANY, [2]Department of Diagnostic and Interventional Radiology and Neuroradiology, University Hospital Essen, Essen, GERMANY, [3]Department of Diagnostic and Interventional Radiology, Medical Faculty, University Düsseldorf, Düsseldorf, GERMANY.

Aim: Prostate cancer (PCa) causes significant morbidity and still is the second leading cause of cancer-related deaths in men in the Western world. ^{68}Ga-labeled HBED-CC-PSMA is a highly promising new tracer for imaging of PCa. The aim of this study was to optimize the acquisition time of ^{68}Ga-PSMA positron emission tomography/magnetic resonance imaging (PET/MRI) in patients with local and metastatic prostate cancer. **Materials and methods**: Eleven patients were administered intravenously with the ^{68}Ga-HBED-CC-PSMA ligand (116 ± 25 MBq) and subsequently underwent PET/MRI at 159 ± 57 min after injection. PET and MR imaging data were acquired simultaneously. PET acquisition was performed in list mode and PET images were reconstructed at different time intervals (1, 2, 4, 6, 8, and 10 min). Data were analyzed at these time intervals regarding PET image quality and radiotracer uptake in tumor lesions and muscle tissue. Uptake was quantified in terms of the maximum and mean standardized uptake value (SUV_{max}, SUV_{mean}) within a spherical volume of interest (VOI). Reference VOIs were drawn in the gluteus maximus muscle on the right side. PET image quality was evaluated visually by experienced nuclear physicians/radiologists based on a 1 - 5 (excellent - insufficient) scale. **Results**: Both SUV_{max} and SUV_{mean} correlated inversely with acquisition time and reached a plateau at acquisition times of 4 min and longer. PET image quality showed a linear correlation with increasing acquisition time, reaching a plateau at 4-6 min of image acquisition. **Conclusion**: The optimal acquisition time of ^{68}Ga-PSMA-ligand PET/MRI in patients with local and metastatic PCa appears to be 4 min per bed position. At this acquisition time, PET image quality reaches its maximum while SUVs do not change significantly beyond this time point.

P038

Development of advanced data acquisition methods for quantitative single photon emission computed tomography

K. MATSUMOTO[1,2,3], Y. Takahashi[4,2], A. Takaki[5], K. Murase[2], Y. Wada[3], Y. Watanabe[3], K. Endo[1]; [1]Kyoto College of Medical Science, Kyoto, JAPAN, [2]Osaka University Graduate School of Medicine, Suita, JAPAN, [3]Center for Life Science Technologies, RIKEN, Kobe, JAPAN, [4]Gunma Prefectural College of Health Sciences, Maebashi, JAPAN, [5]Fujifilm RI Pharma Co., Ltd., Tokyo, JAPAN.

Aim: The cerebral blood flow and metabolism SPECT images require high signal to noise ratio and spatial resolution for precise evaluation of the abnormal radioactive tracer distribution in the brain. The asymmetric SPECT acquisition such as an odd number of projections is significantly improved reconstructed image quality, because for an odd number of projections the sampling interval is half of the angular step of the detector and the number of angular sampling points is doubled. The interpolated projection data estimation (IPDE) method also improve the image quality, but the spatial resolution is degraded. On the other hand, the DRAMA (Dynamic RAMLA) is an iterative algorithm similar to the RAMLA, provides fast convergence with a reasonable signal to noise ratio by updating the image with row-action by applying the subset-dependent relaxation parameter. The purpose of this study was to develop a Hybrid SPECT reconstruction method by a combination of the asymmetric SPECT acquisition, IPDE method and modified DRAMA reconstruction algorithm. Methods:A Hybrid SPECT reconstruction method was evaluated to a two-dimensional Shepp-Logan head numerical phantom with statistical noise and a Hoffman 3-D brain phantom. A gamma camera, GE Healthcare Millennium MG, were used to scan images of a Hoffman 3-D brain phantom. For 360° SPECT, we simulated 16, 32 and 64 projections with an array 128 pixel per projection. Attenuation and scatter corrections of the Hoffman 3-D brain phantom SPECT image were performed using Chang's method and a modified triple energy window, respectively. Quality of the reconstructed images was evaluated in terms of mean structural similarity (MSSIM) values and a two dimensional power spectrum analysis. Results:As for the numerical phantom, the MSSIM values of each projections were 0.9584±0.0151 (16 projections), 0.9595±0.0308 (32 projections) and 0.9511±0.0433 in the 64 projections, respectively. In the radial distribution function of a two dimensional power spectrum analysis, each phantom SPECT images quality using Hybrid SPECT reconstruction method were approximately 1.5 times better than conventional method. Conclusions:The Hybrid SPECT reconstruction method showed faster resolution

recovery with lower noise than the asymmetric SPECT acquisition and IPDE method and yielded acceptable images in 2 or 3 iteration.

P039

Effects of mis-registration of CT attenuation-corrected on myocardial perfusion images acquired using multi-focus fan beam collimator SPECT/CT and conventional SPECT

H. ONISHI[1], K. Nakamoto[2], S. Kenda[3], Y. Kangai[1], N. Yada[1], T. Saho[1], T. Sakai[3], D. Hasegawa[3], M. Fukunaga[3], H. Amijima[4]; [1]Program in Biological System Sciences, Graduate School of Comprehensive Scientific Research, Prefectural University of Hiroshima, SHOBARA, HIROSHIMA, JAPAN, [2]Department of Radiology, Hiroshima prefectural Hospital, HIROSHIMA, HIROSHIMA, JAPAN, [3]Program in Health and Welfare Sciences, Graduate School of Comprehensive Scientific Research, Prefectural University of Hiroshima, MIHARA, HIROSHIMA, JAPAN, [4]Graduate school of nursing,Hyogo University of Health Sciences, KOBE, HYOGO, JAPAN.

Aims: Algorithms for attenuation correction in SPECT/CT systems have potential for mis-registration. The present study compares mis-registration of computed tomography attenuation correction (CTAC) in IQ-SPECT and conventional (180° apart: C-mode) myocardial perfusion images (MPI). Methods: Images were acquired from seven healthy volunteers who independently underwent SPECT/CT using 740 MBq of 99m-Tc-tetrofosmin, a parallel-hole collimator (LEHR) and the same system with IQ-SPECT (IQ-mode) modification using SMARTZOOM. C-mode images were acquired over 180°-contoured orbits with 30 views/detector for 12.5 s into 64 x 64 matrices and 4.8-mm pixels. We acquired IQ-SPECT images over 208°-cardiocentric orbits with 17 views/detector for 6.25 s/view into 128 x 128 matrices and 4.8-mm pixels. Both images were attenuation-corrected using CT images. The reconstruction software was Flash3D and specific Flash3D (OSCGM) for IQ-mode. The MPI SPECT/CT registration shifted the CT data by ±1, ±2, ±3 pixels along the cephalad/caudal, dorsal/ventral and left/right axes. The % uptake in 5-wall AC-MPI polar maps was scored for each region and the direction of the shift along each axis was statistically analyzed using Student's t test. We compared regions of mismatch on non-shifted images in C- and IQ-modes. Results: The % uptake did not significantly differ between shifted and non-shifted images when mis-registration affected only 1 or 2 pixels. The most significant effects on % uptake on AC polar maps were 16.6% and 5.2% changes in the lateral wall caused by a 3-pixel ventral shift in C ($p = 0.002$) and IQ ($p = 0.29$) modes, respectively. A 3-pixel dorsal shift resulted in statistically significant 13% ($p = 0.0001$) and 3.6% ($p = 0.43$) septal changes in C and IQ-modes, respectively. The significant change in IQ-mode was caused by three ($p = 0.009$) and two-pixel ($p = 0.04$) cephalad shifts. The mismatch in IQ-mode was increased by 10% - 20% compared with that in C-mode without changes in the septum and inferior wall caused by a right shift. A 3-pixel right shift increased the mismatch of the septum and inferior wall to 49.5% in IQ-mode. However, the mismatch in IQ-mode was improved by 52.2% compared with a 3-pixel ventral shift in the lateral and inferior wall in C-mode. Conclusion: Excessive mis-registration along the dorsal/ventral axis affected the quality of AC myocardial perfusion images most significantly. These findings suggested that mis-registration affects IQ-mode less than C-mode in MPI SPECT/CT images.

P040

Optimisation and clinical impact of PSF modelling reconstruction in PET-CT

B. J. Corcoran, C. Scott, D. RUIZ, E. Kalogianni, A. Eccles; King's College Hospital, London, UNITED KINGDOM.

Aims: To quantify the impact on PET image quality of PSF modelling in the reconstruction of time-of-flight PET/CT. Method: Images of a NEMA Image Quality phantom containing 6 spherical inserts, activity ratio of 4:1 hot spheres to background, were acquired on a GE Discovery 710 PET/CT scanner. The data was reconstructed with the existing clinical protocol: VPFX (VUE point FX, 2 iterations, 24 subsets). Further reconstructions then included the SharpIR (GE Healthcare) PSF modelling: VPFX+PSF (VUE point FX + SharpIR, 1/2/3/4/5 iterations and 24 subsets). Image quality parameters were calculated: coefficient of variation (CoV), signal to noise ratio (SNR) and contrast recovery (CR). Following the phantom study 19 patients were retrospectively reconstructed using VUE point FX (2 iterations, 24 subsets) with and without SharpIR correction. SUVmax and CoV were assessed in the liver. A 60mm diameter circular region was drawn on 3 different slices in the liver for each patient and the average calculated. Changes in SUVmax were calculated for all identified lesions. Results: Visual analysis of the phantom data, contrast recovery curves and SNR curves for the 6 inserts identified the optimum image quality for the reconstruction with VPFX+PSF (2 iterations, 24 subsets). In the patient study; for the VPFX+PSF reconstruction compared to the VPFX reconstruction, the mean difference in the CoV of liver regions was -9.2% and the SUVmax was -0.7%. For the lesions identified (n=56) the measured changes in SUVmax: increased (41), no change (6), decreased (9). Conclusion: We have optimised our reconstruction for time-of-flight plus PSF corrected acquisition. As shown by other authors the signal to noise is reduced in the

image by the application of PSF correction. The uncertainty in the effect on the SUVmax presents a challenge for its routine clinical use in quantitative analysis. Further work will investigate the effect of the PSF correction on tumour detectability.

P041

Influence of SPECT reconstruction algorithm on diagnostic accuracy of parathyroid scintigraphy: comparison of iterative reconstruction with filtered backprojection

G. Kara Gedik, O. Sari; Selcuk University Faculty of Medicine, Department of Nuclear Medicine, Konya, TURKEY.

Aim:The purpose of this study was to evaluate retrospectively the value of technetium-99m (Tc-99m) methoxyisobutylisonitrile (MIBI) single photon emission computed tomography (SPECT) and to compare the diagnostic accuracy of iterative reconstruction (IR) and filtered backprojection (FBP) reconstruction algorithms about localization of parathyroid lesions. Materials and methods:Forty-four patients with primary hyperparathyroidism (37 women and 7 men, age range: 26-76 years, mean age: 53.75±12.39 years), in whom histopathological correlation could be performed and who were cured after resection of abnormal parathyroid glands were included into the study. Mean serum PTH and calcium levels were 241.97±210.7 (range: 65-940 pg/ml, reference value: 12-65 pg/ml,) and 11.30±0,88mg/dl (range: 10-14.4 mg/dl, reference value: 8.4-10.2 mg/dl), respectively. Dual phase Tc-99m parathyroid scintigraphy, in which planar views were obtained 20 and 120 minutes after injection of 740 megabecquerel(MBq) Tc-99m MIBI, was performed with a dual-headed gamma camera (Siemens, Ecam signature) in all patients. Tomographic images were acquired 120 minutes after the administration of radiopharmaceutical. The SPECT datas were evaluated using an IR (ordered subsets expectation maximation) as well as a FBP algorithm. In 23 of 44 patients SPECT acquisitions were performed in 64x64 matrix, in the remaining 21 patients, tomographic datas were collected in 128x128 matrix. The imaging results were compared to pathological findings and sensitivities of both reconstruction algorithms and planar views were calculated. Results:Using planar MIBI scans, abnormal parathyroid glands were correctly localized in 75% of the cases. Sensitivity increased to 77% using SPECT with FBP and rose to 84% with IR. When the sensitivities were further calculated according to the acquisition matrix, it is found that in patients in whom 128x128 matrix was used, the sensitivities were 95% (20/21) and 85% (18/21) for IR and FBP, respectively. The sensitivities were lower in patients who were imaged with 64x64 matrix; with IR it was calculated as 74% (17/23) whereas with FBP, the sensitivity was 70% (16/23). Conclusion:In conclusion, compared to planar scintigraphy, Tc-99m MIBI SPECT is a more sensitive diagnostic modality in the detection of abnormal parathyroid tissues. Image quality and sensitivity further improves when larger matrices with IR are used instead of FBP algorithm.

P042

Optimization of image processing for better anatomical analysis of the striatum for SPECT scans of [99mTc] TRODAT-1

A. C. Trevisan[1], L. A. Santos[2], F. A. Pitella[2], E. N. Itikawa[1], M. Kato[2], V. Tumas[2], M. M. C. M. Brito[2], L. Wichert-Ana[2]; [1]Universidade de São Paulo, São Carlos, BRAZIL, [2]Universidade de São Paulo, Ribeirão Preto, BRAZIL.

AIM: Parkinson's disease (PD) is characterized by chronic, progressive and degenerative disorder. Brain SPECT scans using 99mTc-TRODAT-1 radiotracer evidence the striatal density of Dopamine Transporters (DAT). This is particularly important in the evaluation of PD. However, there was a need for standardized protocols for image reconstruction and processing, looking for a high image quality, and the reliability of medical reports. Particularly important are the identification of striatal morphology and the use of appropriated spatial resolution, contrast and noise. This study aimed to investigate the better image processing parameters associated with high morphological identification of striatal body. MATERIALS AND METHOD: Data were acquired in the BrightView XCT - PHILIPS using an anthropomorphic striatal phantom RS-900T, and the reconstruction algorithm was the iterative algorithm OSEM (Ordered Subsets Expectation Maximization). By choosing the iterations(i) (2,0 to 60,0) and subsets(s) (4,0 - 8,0 -16,0) by one independent specialist with grades 0-5, very bad to very good. After that the projections were reconstructed by varying the cutoff (0.1 - 0.3 - 0.5 - 0.7 - 1.0 - 1.5 - 2.0) and order (0.0 - 1.0 - 2.0 - 4.0 - 6.0 - 8.0 - 10.0) of the Butterworth filter, totaling 49 images. In a descriptive analysis of 3 specialists, there was the application in 0-10 grades, also was divided to very bad to very good. RESULTS: According to the analysis, using 3i 8s, it ensures higher quality reconstruction, differentiating the putamen and head of the caudate nucleus. It also found that the greater the number of iterations, worst was the image, with a higher incidence of noise and low spatial resolution; similarly, the higher the number of subsets, also worst was the image. Through a linear regression, with the average grade of 3 experts, we found that the best cutoff independent variable was 0,5 and the best order independent variable was 0, 0. But the image built with both variables, got better. Then the proposed range to obtain a quality image was 1.2 to 1.5 cutoff and varying the order of 0.0 to 10.0. CONCLUSIONS: This study found that the variables cutoff and order are not so good when it work independent. The above proposed range of cutoff

and order assured images with high contrast, high spatial resolution and low noise. This processing protocol enable the accurate differentiation of putamen and the head of the caudate nucleus, helping specialists to better delineate the striatal body.

Continuous-spectrum Emission Tomography (CET) for quantifying the absorbed dose of in-vivo bremsstrahlung

S. Vandenberghe[1], H. W. A. De jong[2], M. Bardies[3], D. Borys[4], M. de Jong[5], S. Walrand[6]; [1]MEDISIP, Department of Electronics and Information Systems, Ghent University, iMinds Medical IT-IBiTech, Gent, BELGIUM, [2]University Medical Center Utrecht, Utrecht, NETHERLANDS, [3]Institut national de la santé et de la recherche médicale, Toulouse, FRANCE, [4] Silesian University of Technology, Comprehensive Cancer Centre, Gliwice, POLAND, [5]Department of nuclear medicine, Erasmus Medical center, Rotterdam, NETHERLANDS, [6]Department of nuclear medicine, UCL, Brussels, BELGIUM.

Introduction: Personalized dosimetry based on quantitative images of radiopharmaceutical distribution in the body can substantially improve the effectiveness of radionuclide therapy. Current nuclear medicine imaging systems are optimized for diagnostic radionuclides and suboptimal for bremsstrahlung X- rays emitted by therapeutic radionuclides.Materials and methods: We present a novel molecular imaging modality, called CET (based on elements from CT, SPECT and PET) and specifically designed for collimating and detecting the high-energy secondary body generated bremsstrahlung X-ray photons. To efficiently detect incoming high-energy X-ray photons, conventional NaI SPECT detectors are replaced with high-density scintillators from PET. A first step in the design of the complete system is the evaluation of monolithic high-resolution detectors for this modality. LYSO, the most commonly used PET scintillator, is intrinsically radioactive due to the presence of Lu-176. This leads to a continuous background in the energy spectrum, making this scintillator not suitable for CET. Therefore simulations (using the input of the continuous Spectrum of Y-90) and measurements of high-density thick PET BGO crystals are compared to the results of conventional NaI detectors. CET also combines these detectors with pinhole collimators (from small animal SPECT), with small acceptance angles and minimal penetration.These are specifically designed for a wide energy spectrum and with the primary aim to reduce scatter and collimator penetration. To efficiently construct these complex collimators with high stopping power, additive manufacturing (3D printing) of tungsten powder will be used. Since no scatter windows can be used for X-rays, quantitative reconstructions will be obtained by modeling the remaining contamination in Monte Carlo-based image reconstruction. Finally Monte Carlo or other approaches will provide the information on the absorbed radiation dose.Results. A BGO detector of 2 inch has a high stopping power of more than 70% for all energies up to 1 MeV. The conventional 3/8 inch NaI works well at low energies but has only 17 % stopping power at 1 MeV. The main advantage of BGO comes from the high amount of direct photo-electric interactions and resulting smaller amount of Compton interactions arriving in lower energy window. A disadvantage of BGO is the smaller amount of scintillation light resulting in reduced energy resolution at lower energies (>30% at 100 keV and 15 % at 1 Mev).Conclusions. All components for building a CET system with specific use in radionuclide therapy have been identified and can be combined into a new molecular multimodality imaging system.

Myocardial innervation and perfusion mismatch using cardiac dual isotope (123I-MIBG/99mTc-tetrofosmin) acquisition on two different CZT cameras: a phantom study

T. Blaire[1,2], A. Bailliez[1,2], D. Legallois[3], D. Agostini[3], A. Manrique[1,3]; [1]EA 4650, Normandy University, Caen, FRANCE, [2]Nuclear Medicine Department, IRIS, Polyclinique du Bois, Lille, FRANCE, [3]Nuclear Medicine Department, CHU Cote de Nacre, Caen, FRANCE.

Purpose: New Cadmium-zinc-telluride (CZT) cameras have dramatically increased sensitivity and energy resolution. This phantom study assessed the impact of dual isotope acquisition on the assessment of 123I/99mTc mismatch using two CZT cameras (DNM 530c, GE Healthcare and DSPECT, Spectrum Dynamics). Materials and methods: We used the anthropomorphic torso phantom (Data Spectrum, Hillsborough, NC) with the cardiac insert, successively filled with a solution of 99mTc alone, 123I alone and a mixture of 123I and 99mTc. Two defects were used: one (13mL) always filled with cold water (mimicking a matched defect) and one (5,4mL) filled with 99mTc when 99mTc solution was in the cardiac insert (mimicking a mismatched defect). A total of 12 datasets on each CZT camera was acquired using both energy windows (99mTc or 123I) with increasing acquisition times (7, 11, 22 and 33 minutes). Segmental uptake (%) for 99mTc and 123I and mismatch (difference of both segmental isotope uptake) were assessed using Corridor 4DM (INVIA Michigan) and a 17-

segment model. Statistical analysis used ANOVA and a linear model including the effect of camera, acquisition type (single vs. dual isotope), isotope (123I and 99mTc) and the interaction between camera type and isotope. Results: There was a slight but significant difference between the 2 cameras (DSPECT-DNM) in assessing 123I-99mTc mismatch in segments encompassing the mismatched defect (segment #5: mean difference: -3.12%, p<0,05; and segment #11: mean difference: -2.25%, p<0,05) . There was no difference in other segments. The linear regression model showed no impact of camera type and acquisition time on the magnitude of the mismatch. Lin's concordance correlation coefficient (CCC) showed an excellent concordance for single and dual isotope acquisition for the assessment of 123I uptake between DNM and DSPECT (CCC>0,82 and 0,93 respectively) and between single and dual isotope within each camera type (CCC>0.98 in DNM and CCC>0.84 in DSPECT). Conclusion: In this phantom study, the two CZT cameras (DNM 530c and DSPECT), with higher energy resolution and sensitivity yielded no significant difference between single (successive) isotope and simultaneous dual isotope acquisition and in the evaluation of myocardial innervation and perfusion mismatch.

P045

Ultrafast Bone SPECT Imaging of the Hands Using a Solid State CZT SPECT Camera

A. Frenkel, M. Kurash, O. Israel, J. A. Kennedy; Rambam Medical Center, HAIFA, ISRAEL.

Aim: To assess the feasibility of fast bone SPECT studies of the hands using a solid state camera (CSS) dedicated for cardiac imaging. Materials and Methods: A Discovery 570c SPECT/CT device (GE Healthcare) was used for phantom simulations and clinical fast SPECT imaging of the hands. Fast SPECT studies were performed using a 350 mL hand phantom filled with 37 MBq Tc99m-pertechnetate and with a 1.5 MBq 5 μL source that simulated a focus of abnormal uptake. Four patients referred for evaluation of pain in their hands were imaged at 2 hours after injection of 925 MBq Tc-99m MDP using a standard camera (Infinia Hawkeye 4, GE Healthcare) for a 10 min spot planar scan of the hands and performed an additional fast, 3 minutes SPECT study of each hand on the CSS. Image quality and diagnostic accuracy of the SPECT studies were assessed and referenced to the standard acquisitions. Results: List mode reconstructions using default regularization in the phantom study on CSS provided images with counting statistics consistent with total activity of 46, 9, and 3 MBq in one hand. The phantom-simulated uptake was clearly visible in low-count images without a negative effect on resolution or contrast. In patient studies, fast acquisition CSS provided good quality tomographic images. Three of the eight hands evaluated in the four patients had a normal appearance on the both the planar and SPECT studies. Six sites of increased focal uptake were found in the additional five hands. Findings on planar and SPECT studies concurred in three foci in the MCPJs and three in the PIPJs. Three foci of abnormal uptake in the MCPJs and one focal uptake in the PIPJ were detected only on SPECT. Conclusions: Phantom simulation studies and clinical studies in 4 patients using the solid state CZT device suggest that bone SPECT of a small anatomical region such as the hand can be successfully achieved providing high quality images and a higher lesion detectability rate associated with a 40 % reduction in acquisition time as compared to standard planar scintigraphy.

18F-Choline intravenously infusion with an automatic combined dispenser and injector system.

A. MORETTI[1], P. CAROLI[2], R. GALASSI[1], V. D'ERRICO[3], C. DONATI[4], L. FANTINI[2], V. MAUTONE[2], G. GUALTIERI[2], G. BATTARA[2], G. PAGANELLI[2], F. MATTEUCCI[2]; [1]NUCLEAR MEDICINE UNIT AUSL ROMAGNA, FORLI', ITALY, [2]NUCLEAR MEDICINE IRST, MELDOLA, ITALY, [3]MEDICAL PHYSICS UNIT tIRST, MELDOLA, ITALY, [4]PHARMACY UNIT IRST, MELDOLA, ITALY.

In nuclear medicine, the doses of radiopharmaceuticals are extracted from multidose vials, using multipurpose fractionators contained within a leaded cell and are then administered to the patient with a manual injection. All these activities cause exposure to radiations to the involved personnel: in order to reduce this exposure, while ensuring the sterility of the preparations and the precision of the administered dose, we evaluated the use of an integrated system for fractionation / injection (Intego® Bayer, Inc., Warrendale, PA, USA).METHODS:We evaluated the fractionating and injecting process of 18F-choline by comparing the automatic mode performed with the Intego® apparel with the usual manual mode of administration of the dose, simulating the above steps for 84 times in a period of two weeks . This simulation involved a total of four operators : three radiology technicians and one nurse; in order to obtain the most accurate and precise meausure of the exposure the personal was monitored by using TDL dosimeters placed on the fingertips both in the Intego® and in the manual mode.Sterility was evaluated by using media fill tests. In order to verify the correspondence between the required dose and fractionated dose, both in the automatic mode than in the manual one, it has been used the same counter properly calibrated.RESULTS:The verification with the media fill test has confirmed the sterility both in the procedure of fractionation / traditional injection than in the one that has used

INTEGO.The accuracy of the fractional dose and subsequently measured in the counter showed a difference between the traditional method and the one with INTEGO lower than the value determined by EANM guidelines (<3%).Compared to traditional methods, the administration with INTEGO showed a much lower (1 MBq than 7 MBq) residual activity in the patient administration set (PAS).From a dosimetric point of view, the comparison between the data of exposure of the involved personnel showed a 75 % reduction (2.36 +/- 0.8 mSv at 0, 6 +/- 0.3 mSv / year).CONCLUSION:Intego® is a useful tool in the operations of fractionation and injection of 18F-choline ensuring accurate and sterile doses and allowing in the same time a significant reduction in the exposure of the personnel

P047

Development of Radionebulizer Equipment for Diagnostic in Nuclear Medicine

A. F. Viana[1], P. Nabinger[1], R. Madke[1], P. Madke[1], P. R. Fereira[2], R. Anele, Filho[3]; [1]Grupo RPH, Porto Alegre, BRAZIL, [2]Bhiosupply, Porto Alegre, BRAZIL, [3]CETA/SENAI, Porto Alegre, BRAZIL.

Ventilation/perfusion (V/Q) SPECT (Single-photon emission computed tomography) of lung are indicated for the diagnostic of pulmonary embolism (PE), alveolitis, chronic obstructive pulmonary disease (COPD), among others. The combination of the ventilation and perfusion exams not only improves the diagnostic accuracy of the method but also facilitates the application of advanced image-processing techniques. In Brazil, many Nuclear Medicine Services are no longer performing the ventilation exam due to the cost of the devices necessary for the inhalation of radioaerosol. The objective of this project was to develop an affordable and easy to use radioaerossol nebulizer device for diagnostic use in nuclear medicine. The radioaerosol production technology is based on the Venturi principle, in which the apparatus is coupled to a source of compressed air producing a suitable aerosol particle (<1.5 microns) to produce pulmonary diagnostic image. The device consists of a ready-to-use blister composed of 2 chambers with isolating valves. This design allows the simple injection of the radiopharmaceutical, its nebulization and the decantation of the particles bigger than the defined size. The blister has two breathing hoses, one for the inhalation and other for exhalation. The system is also composed of a lead shield that accommodates the blisters perfectly, and protects the patient and operator from energies of 140 KeV, and a mechanism to hinder the reutilization of the blister, avoiding crossed contamination between patients. Our team was able to develop an inexpensive blister and lead shield that is reimbursed by the Brazilian Heath Care System (SUS). This project was supported by a Brazilian Federal grant from SENAI/SESI and has the patent deposit number BR 10 2014 029318 3.

Monte Carlo Simulations of Beta Particle Measurement Using Cerenkov Luminescence Imaging or Beta Detection

L. Altabella, C. R. Gigliotti, A. E. Spinelli; San Raffaele Scientific Institute, Milano, ITALY.

Aim: Recently Cerenkov luminescence imaging (CLI) has been introduced as a novel tool to image in vivo the biodistribution of beta plus and beta minus emitters for both human and animal models. CLI is normally performed using a CCD detector in combination with a set of lens and filters. In this work we investigated through Monte Carlo simulations the feasibility of beta imaging of small animals with CLI or direct and indirect beta detection using beta emitters commonly used in Nuclear Medicine. CLI is based on the detection of Cerenkov photons generated in the medium when beta particles travel with a velocity greater then the speed of light in the medium. Direct and indirect beta detection are based on direct interaction with the detector or a conversion into light by means of a scintillator.Materials and methods: Monte Carlo simulations were implemented using Gamos plug-in for Geant4. We considered a slab of mouse muscle and a radioactive point sources of 32P and 90Y placed at different depth from 1 mm to 3 mm. Cerenkov photons and beta particles are collected at the exiting surface in detector direction. For indirect detection a 0.2 millimeter CsI(Tl) scintillator has been positioned at the top detector.Results: Direct beta detection show a better resolution (FWHM 2.32 mm for 32P and 2.44 mm for 90Y at 1 mm depth) with respect to CLI (FWHM 3.69 mm for 32P and 3.98 mm for 90Y at 1 mm depth) in spite of less counts. For superficial sources and direct beta detection no significant differences are found in resolution between 32P and Y90, while 32P shows a better resolution for CLI with respect to 90Y at deeper source (about 1 mm difference for 3 mm source depth). For indirect beta detection, we obtain a FWHM of 2.71 mm with 1 mm source depth.Conclusion: Direct or indirect CCD beta detection represents a good set up in terms of spatial resolution for beta radionuclide imaging however only a limited field of view (FOV) can be usually covered with this imaging setting. On the other hand CLI allow a much larger FOV (several cm) using conventional small animals optical imaging systems and is thus a more flexible approach.

P049
Attenuation Correction in Planar Scintigraphy Using Transmission Measurement with Flood Source

M. Samal, V. Sirova, D. Skibova, J. Trnka, V. Ptacnik, J. Kubinyi; Charles University Prague, Prague, CZECH REPUBLIC.

In planar scintigraphy, Tc-99m flood source is used for transmission measurement and subsequent attenuation correction (AC) in Tc-99m emission data. Alternative Co-57 flood source is faster, safer and easier to use but emits lower energy radiation. The aim of the phantom study was to test Co-57 flood source for AC in Tc-99m emission data. Methods: Two 100 ml plastic vials were attached to the rods of Jaszczak phantom and filled with 2 different activities of Tc-99m. Volume of the phantom was filled with inactive and active water backgrounds (1:8 and 1:4 with respect to a weaker vial). Emission measurements were made simultaneously by 2 camera detectors in upper and lower positions. Transmission measurements (with inactive phantom) were performed using Tc-99m and Co-57 flood sources placed below the phantom on elevated edges of lower detector. Acquisition was performed in photopeak and scatter windows. Two types of transmission images were recorded with each flood source: (a) with and without phantom by upper detector only, (b) with phantom by lower and upper detectors simultaneously. Recorded data were checked for registration and corrected for decay, table attenuation and detector sensitivity. Geometric mean (GM) of emission data was corrected for attenuation and background. Scatter was compensated using dual-energy window (DEW) or broad-beam (BB) attenuation coefficient. Recovery of total activity in both vials and relative activity in the vial with higher activity were calculated as percentage of simulated activity and percentage of total measured activity in both vials. Results: Phantom thickness calculated pixel-wise reflected well mechanical dimensions of the phantom. Tc-99m and Co-57 thickness maps were applied to correct GM data. Without AC, only 30% of simulated activity was recovered. Recovery increased to 91-92% using BB attenuation coefficient 0.12 and to 100-104% using DEW and attenuation coefficient 0.15. Best recovery (100-101%) was obtained using BB attenuation coefficient 0.13. No significant differences were found between Tc-99m and Co-57 maps and the 2 methods of transmission measurement. Regardless of AC, relative activity of stronger source (65%) was recovered accurately with mean absolute error of 0.97%. Estimated dose to the patient from 1-minute exposure to Co-57 flood source of medium activity was below 5 microSv. Conclusion: Pixel-wise maps of object thickness obtained by transmission measurements using both Tc-99m and Co-57 flood sources are sufficiently accurate to correct for attenuation in geometric-mean Tc-99m emission data. Using the simple method, planar scintigraphy can approach quantitative accuracy comparable with more sophisticated techniques.

P050
The Influence of Cardiac ROIs Contour Definition at Heart-to-Mediastinum Ratio in 123I-MIBG Scintigraphy

A. Sá Pinto, T. Vieira, S. Chaves, V. Alves, T. Faria, A. Oliveira, A. Fernandes, M. Pérez, J. Pereira; Centro Hospitalar de São João, Porto, PORTUGAL.

Aim: Metadiodobenzylguanidine labelled with 123I (123I-MIBG) is used for assessing the myocardial adrenergic system. Despite its highly independent prognostic value in heart failure, it is important to improve standardized acquisition methods and assessment criteria. We aim to study the correlations of the heart-to-mediastinum ratios (H/M) obtained through the application of different regions of interest (ROIs) at the heart, and with different acquisition methods.Methods and Material: Six patients sent to our Nuclear Medicine Department for oncological evaluation were randomly selected. Images' acquisition started 3 hours post-injection of 123I-MIBG (185-370 MBq). Twosequential thoracic static (TS) images, of 5 minutes (5M) each, were acquired (LEHR collimators; 256x256 matrix; 20% energy window set on 159 keV); immediately after, this step was repeated using ME collimators. Then, a whole body (WB) scanning was acquired (LEHR collimators; 256x1024 matrix; scan speed of 10 cm/min). Scatter Correction (SC) was applied defining a second window (130 keV +/- 10%), during the acquisition of TS and WB imaging, when using LEHR collimators. Ten minute images (10M) were obtained summing the counts in the sequential 5 minute images. Three different types of cardiac ROIs were drawn by one experienced observer (irregular manual [MAN], elliptical [ELI, 900 pixels area] and circular [CIR, 21 diameter]) while one rectangular ROI (120 pixels area) was placed at the mediastinum (M). Eight images were used to calculate H/M ratio for each patient (MAN/M, ELI/M and CIR/M): 5M/LEHR, 5M/LEHR/SC, 10M/LEHR, 10M/LEHR/SC, 5M/ME, 10M/ME, WB, WB/SC. MAN/M, ELI/M and CIR/M ratios were defined as the ratio of average counts at the heart and mediastinum. The correlations of MAN/M with ELI/M (C1), MAN/M with CIR/M (C2) and ELI/M with CIR/M (C3) were analyzed using IBM SPSS version 22.0.Results: Concerning C1, we obtained $rs = 1$ ($p < 0.001$) for the 8 images. Regarding C2, $rs = 0.943$ ($p < 0.005$) for images 5M/LEHR, 5M/LEHR/SC, 10M/LEHR and WB; for images 10M/LEHR/SC, 5M/ME, 10M/ME and WB/SC the $rs = 1$ ($p < 0.001$). C3 had a $rs = 0.943$ ($p < 0.005$) for images 5M/LEHR, 5M/LEHR/SC, 10M/LEHR and WB; for 10M/LEHR/SC, 5M/ME, 10M/ME and WB/SC the $rs = 1$

($p < 0.001$).Conclusion: H/M ratio values obtained with different methods of cardiac contour in 123I-MIBG scintigraphy seem to have excellent correlation across several methods of image acquisition. Collimation and electronic SC, as well as the duration of acquisition, may influence ROIs' definition.

Performance Evaluation of a Gamma-Probe for High Energy source (131-Iodine) for Oncologic Purposes

E. N. I. Itikawa[1,2], L. A. S. Santos[1,3], D. K. S. Sonvenso[1,3], M. K. Kato[1,3], F. A. P. Pitella[1,3], C. E. P. B. Baltazar[1,4], A. C. T. Trevisan[1,2], E. R. M. Moraes[1,5], **L. W. A. Wichert-Ana**[1,2,3]; [1]Ribeirão Preto School of Medicine, Ribeirão Preto, BRAZIL, [2]Post-Graduation Program Interunits Bioengineering EESC/FMRP/IQSC-USP, São Carlos, BRAZIL, [3]Postgraduation Program in Internal Medicine, Ribeirão Preto, BRAZIL, [4]Faculty of Philosophy, Sciences and Literature of Ribeirão Preto, Ribeirão Preto, BRAZIL, [5]Faculty of Philosophy, Sciences and Literature of Ribeirão Preto, Ribeirão Preto, Ribeirão Preto, BRAZIL.

AIM: To evaluate spatial, angular and energy resolution; shielding and sensitivity of a high energy gamma-probe according to international standards for non-imaging intraoperative probes. The objective was to assure its usefulness in sentinel lymph node localization and reminiscent thyroid cancer.
MATERIAL AND METHODS: We tested the wide-range energy isotope (0.11-1 MeV) CsI-Tl probe. Low activity sources of 99m-Tc and 131-I were used in the performance tests. Spatial, angular and energy resolution were calculated in terms of FWHM. Shielding was calculated based on the intrinsic sensitivity in the probe axis. The collimator device was used to evaluate shielding; angular and spatial resolution. All the tests of this study were designed as suggested by international standards for non-imaging intraoperative probes and studies in the literature.
RESULTS: The probe was capable to solve two closely sources of 131-I and 99m-Tc only by using the collimator device in the spatial resolution test. Values of 18.3 and 10.91-FWHM(mm) were achieved, respectively. Angular resolution showed similar performance for 131-I and 99m-Tc, with better results by using the collimation. We found values of 51.4 and 29.2-FWHM(°), respectively. Energy resolution showed a value of 13.2-FWHM(%) for 131-I. Shielding test showed that the probe tip was not capable to stop high-energy photons of 131-I as desirable, even increasing lateral thickness with the collimator device. Better results were obtained with 99m-Tc. The sensitivity test showed a value of 682 and 276-cps/MBq for 131-I and 99mTc, respectively. **CONCLUSIONS**: Consistent results in the tests were achieved only by using the collimator device. Meanwhile, the use of the intraoperative probe without the collimator should not be discarded. We must consider that the tested high-energy gamma-probe needs a robust design such as a thicker lateral shielding. Furthermore, it could not be achieved without increasing the size of the crystal detector because thicker and high-density crystals tend to effectively stop high-energy photons. On the other hand, it affects geometric parameters of detection, i.e. spatial and angular resolution. Thus, the collimator was prior to improve spatial and angular resolution as it reduces the field of view of the crystal detector. Our study design is according to international standards for evaluation of non-imaging gamma probes and showed feasible results that corroborates to accurate localization in oncological intervention, i.e. melanoma, thyroid and breast cancer.

P052

Evaluation of Physical Detection Parameters of a Gamma Probe for Sentinel Lymph Node Localization in Melanoma and Breast Cancer.

E. N. I. Itikawa[1,2], L. A. S. Santos[1,3], D. K. S. Sonvenso[1,3], M. K. Kato[1,3], F. A. P. Pitella[1,3], C. E. P. B. Baltazar[1,4], A. C. T. Trevisan[1,2], E. R. M. Moraes[1,5], **L. W. A. Wichert-Ana**[1,2,3]; [1]Ribeirão Preto School of Medicine, Ribeirão Preto, BRAZIL, [2]Post-Graduation Program Interunits Bioengineering EESC/FMRP/IQSC-USP, São Carlos, BRAZIL, [3]Postgraduation Program in Internal Medicine, Ribeirão Preto, BRAZIL, [4]Faculty of Philosophy, Sciences and Literature of Ribeirão Preto, Ribeirão Preto, BRAZIL, [5]Faculty of Philosophy, Sciences and Literature of Ribeirão Preto, Ribeirão Preto, Ribeirão Preto, BRAZIL.

AIM: To evaluate angular, spatial and energy resolution, side and back shielding and the final sensitivity according to international standards of quality control for non-imaging probes. The objective in our work was to assure its usefulness in sentinel lymph node localization in patients with melanoma and breast cancer patients.
MATERIAL AND METHODS: We used a CZT probe detector EUROPROBE II ® (Eurorad, Italy) for low energy isotope (20 ~ 170 keV). The tests were performed with low activity 99m-Tc radiation sources (12 MBq upper) and also, acrylic devices for point sources and scatter medium simulators were developed to run the tests. Count acquisition was performed through time integration mode. Shielding, angular, spatial and energy resolution were also evaluated by using a collimator, a device that increases the lateral shielding and decreases the sensitive area of the detector tip, in the shielding, angular, spatial and energy resolution tests. **RESULTS**: The probe showed 31.4° and 31.6°-FWHM for 3 and 30

centimeters-distance, respectively, in the angular resolution test. Spatial resolution showed the capability of the probe to solve two closely sources of radiation through a scatter medium of 10 mm as well as the resolution test, which demonstrated a 20.5-FWHM(%) and proved to correctly discriminate the photopeak of 99m-Tc (140-keV). The gamma probe also showed good intrinsic sensitivity of 510 counts per second per unit of activity (cps/MBq), value within the suggested by its guideline in similar conditions of detection. Finally, the side and back shielding test proved that the probe tip is efficient to stop photons that come from residual or background radiation. We observed similar performance in the tests when using the collimator. As expected, the reduction of the sensitive area by the device improved the visualization of both point sources in the spatial resolution test, and reduced the FWHM values in the angular resolution test. **CONCLUSION**: The tested gamma probe showed results which are according to the international guideline for non-imaging intraoperative probes and results found in the literature. Gama probe has an important rule to access sentinel lymph nodes under difficult conditions of localization. Indeed, this tool is expected to have detection parameters consistent to this purpose and, through the results of our study, which is according to the international standard of quality criteria for non-imaging probes, we can attest its feasibility for applications in oncology.

P53

The General Idea and the Functionality Behind Real-time Handheld Emission Spot Allocator (rthESA) for Simultaneous Fusion Imaging with Ultrasound

C. Kühnel, T. Winkens, M. Freesmeyer; Jena University Hospital, Jena, GERMANY.

Objectives: First, to report on initial experiences and technical parameters of a newly developed real-time handheld emission spot allocator (rthESA), and second, to report on the simultaneous acquisition of rthESA and US data as rthESA/US fusion images. Methods: The rthESA consisted of five semiconductor-detectors made of Cd-Zn-Te arranged in alternate position in two rows. This design allowed the examination of focal activities in the same plane as US. The signals were interpreted by an ad hoc software (algorithm) and the real-time allocation of spot radiation sources within air- and water phantoms was investigated for 99mTc, 131I, and 18F. A compact intraoperative US probe (39mm transducer) was fixed in plane with the rthESA and connected to a standard US equipment. Experiments with a liver phantom were performed to verify the integration of 99mTc-rthESA data and US images. Results: The allocation proved to be successful for all radionuclides. The system showed a noticeable performance latency, most pronounced for positions far from the detector (1cm distance: 0.7 ± 0.5 sec; 4cm distance: 6.1 ± 3.2 sec). Within the liver phantom, the rthESA enabled the correct allocation of a spot radiation source within a live US image. Conclusions: The rthESA allowed an exact localization of spot radiation sources in single plane, with additional consideration of the distance from the detector, leading to real-time allocation and simultaneous overlay with US images. In spite of clear technical limitations in need of further development, this proof-of-concept study shows that this hybrid detector has the potential to provide integrated simultaneous nuclear medicine and US images.

P54

Hybrid Integration of Real-Time Ultrasound and Freehand-SPECT: First Experiences and additional informations about Radiation Exposure of the Investigator

C. Kühnel, T. Winkens, T. Opfermann, M. Freesmeyer; Jena University Hospital, Jena, GERMANY.

Objectives: Hybrid imaging has been a successful way to overcome the limitations of functional imaging. However, no integrated concept for combining ultrasound with nuclear medicine imaging has been presented up to date. We investigated the feasibility of a quasi-integrated free-hand single photon emission tomography/ultrasound (99mTcO4-fhSPECT/US) fusion imaging concept in patients with thyroid diseases. Additionally, the radiation exposure of the investigators' hand was assessed during 99mTcO4-fhSPECT/US of the thyroid. Methods: Thirty four patients were examined. After application of 75 MBq 99mTc pertechnetate intravenously, fhSPECT was performed using declipseSPECT® (SurgicEye, Munich, Germany) and navigated ultrasound using LOGIQ® E9 (GE Healthcare, Milwaukee, WI, USA). Three-dimensional SPECT data were reconstructed and transferred to the ultrasound system. The combination of two independent positioning systems enabled real-time fusion of metabolic and morphologic information during ultrasound examination. Conventional dosimetry was performed by rings with thermoluminescence detectors (TLD) and compared with the ambient dose rate, which was measured by dose rate meters (DRM), and the measurement time. Results: All examinations were technically successful. Only minor limitations in fusion offset occurred. The fhSPECT system's poor spatial resolution was the reason for further limitations. The mean

exposure per investigation was 7.53 μSv by ring dosimetry and 9.02 μSv by DRM. Conclusion: FreehandSPECT/ultrasound fusion concept proved feasible and applicable; however, technical improvements are necessary. The hand exposure in clinical routine is not expected to add a relevant risk.

P55

An integrated framework of recovering triple coincidence for enhancing PET sensitivity

H. Lin, Z. Wei, C. Chiang, K. Chuang; National Tsing Hua university, Hsin Chu, TAIWAN.

Aims: Triple events caused by simultaneously detection of three photons are usually discarded as the annihilation information being mixed with another detection induced from one of the annihilation photons scattering (inter-detector scattering triple, IDS) or from an annihilation photon from a separate decay (random triple, RnT). In addition, for non-pure positron emitter, a particular positron-gamma (β+γ) triple can be produced due to the presence of the cascade gamma ray. The majority of the triple coincidence contains the true photon pair that can be possibly recovered. To this end, we proposed an integrated framework of recovering triple coincidence events to enhance the sensitivity of PET imaging for pure and non-pure positron emitters.Materials and Methods: Multiple energy window settings were first used to classify the triple event into IDS, RnT and β+γ events. Then, different recovering strategies for IDS, RnT, and β+γ triple using combined likelihoods based on energy, temporal and double coincidence information were developed to identify the true LOR. A Biograph mCT PET scanner was modeled with a house-made GATE/MPHG Monte Carlo code. We evaluated the performance of the proposed method on a NCAT phantom at various activity levels of F-18, I-124, and Br-76.Results: Preliminary results using the simulated data show that the accuracy of recovering triple coincidence can achieve around 87% for IDS, 90% for RnT, and 82% for β+γ at 10 mCi. We found that about 15% of the triple coincidence for F-18 can be recovered using the proposed method, while increasing this ratio substantially for non-pure emitters (28% for I-124 and 43 % for Br-76).Conclusion: We conclude that the proposed integrated framework can improve the counting statistics of clinical PET imaging for pure and non-pure positron emitters, especially in high activity PET imaging.

Monte Carlo Modelling and Experimental Verification of a GE Optima SPECT System: Towards Characterisation of Collimator Response

A. Grimwood[1], T. Kostou[2], P. Papadimitroulas[2], G. Loudos[2], L. Livieratos[3], J. Scuffham[1]; [1]Royal Surrey County Hospital, Guildford, UNITED KINGDOM, [2]Technological Educational Institute of Athens, Athens, GREECE, [3]King's College London, London, UNITED KINGDOM.

Aim: Monte Carlo simulations are an effective tool for characterising detector performance [1]. We employ the GATE application to model the GE Optima SPECT system. Our goal is to characterise detected photons by their interactions (direct, scattered and septal penetration) through simulation. This information can be used to optimise reconstruction of real image data [2]. To be effective, there must be good agreement between simulated and experimental results. This project is a verification between the clinical system and simulated model.
Materials and methods: The Royal Surrey County Hospital operates a GE Optima NM/CT 640 for I-131 sentinel lymph node imaging. High energy scatter and septal penetration artefacts are prevalent and can obscure features in these images. Using manufacturer specifications, the Optima system was modelled in GATE 7.0, a Monte Carlo simulation application built upon GEANT4, using a standalone PC. Simulated spectra were acquired from point sources for both Tc-99m and I-131 to characterise system performance in three configurations (intrinsic, extrinsic and in-phantom). The simulated spectra were then compared with experimental data to verify the model. Finally, spectra for direct, scatter and septal penetration detections were acquired from the simulation results and used to characterise their relative contributions to the overall spectrum. This in turn enabled us to model the collimator-detector response function.
Results: Good agreement has been achieved between the simulated and experimental spectra for both Tc-99m and I-131 sources. The separate contributions of direct, scatter and septal penetration detection events have been identified. It is demonstrated that these adequately describe features including: the characteristic lead X-ray peak, scatter peak and photopeaks. From the spectral data, collimator-detector response function was described for a simple point source planar image.
Conclusion: An effective Monte Carlo model of a clinical SPECT system has been constructed and used to characterise imaging performance using modest computing resources. Experimental verification has established the validity of the model. This sets the foundation for using the simulation as a tool in future work to optimise image acquisition and reconstruction parameters, such as energy windowing and resolution recovery.

Preclinical validation of automated DXA- and CT-based body composition measurements

J. Devriese[1], L. Beels[2], A. Maes[2], C. Van de Wiele[2], O. Gheysens[2], H. Pottel[1]; [1]KU Leuven campus Kulak, Kortrijk, BELGIUM, [2]Department of Nuclear Medicine, AZ Groeninge, Kortrijk, BELGIUM.

Aim: Semi-quantitative evaluation of tumor metabolic activity is possible through calculation of the standardized uptake value (SUV), defined as the ratio of measured radioactivity concentration to the injected dose per unit of volume of distribution. SUV is traditionally normalized for body weight. Lean body mass (LBM) has also been proposed as volume of distribution, since e.g. 18F-FDG distribution in fatty tissues is limited. LBM can be estimated by predictive equations, or measured by e.g. dual-energy X-ray absorptiometry (DXA) or computed tomography (CT). Accurate LBM measurements would lead to accurate and reproducible LBM-normalized SUVs. The purpose of this study is to determine and validate a set of Hounsfield unit (HU) ranges to segment CT images into tissue types and to test the validity of DXA tissue segmentation on pure, unmixed porcine tissues. Materials and methods: This preclinical prospective study was approved by the local ethical committee. Different quantities of porcine bone tissue (BT), lean tissue (LT) and adipose tissue (AT) were scanned using DXA and CT. Tissue type segmentation in two equal type DXA devices was performed via the standard clinical protocol and in CT through two different sets of Hounsfield unit (HU) ranges (Baracos et al., 2010, Clarys et al., 2010). Percent coefficients of variation (%CV) were used to assess precision while % differences of observed masses were tested against zero using the Wilcoxon signed-rank test. Results: Total mass is significantly underestimated by both DXA devices from true mass by 6.8% and 8.1% ($p = 0.016$). Total mass estimated by CT using both sets of HU ranges differ from true mass by 1.7% and 2.0% ($p = 0.69$). Both DXA devices systematically underestimate tissue type masses (BT, LT, and AT). BT mass differs from true BT mass by 78.2% and 75.8%, and for other tissue types masses are underestimated by 10.4% and 8.1% (LT) and 8.3% and 11.3% (AT). CT does not systematically over or underestimate tissue type mass. There are smaller differences from true mass, ranging from -8.8% to 10.4%. Conclusion: Automated tissue segmentation using CT images and a solid set of HU ranges is a valuable method, since these measurements were reproducible and accurate. This technique offers several possibilities in future research and clinical settings, and can become a valuable tool in quantitative nuclear medicine.

P58

Evaluation of image quality on PET/CT with Flow motion technology –Does it keep quantitative performance and uniformity ? -

K. Murakami, T. Nakahara, Y. Ogata, Y. Iwabuchi, M. Katagiri, Y. Matsusaka; Keio University, Tokyo, JAPAN.

Øbject: To compare image quality obtained by continuous table motion (Flow motion technology; FMT) to conventional method (Step and shoot; SS).This time we focused to compare quantitative performance and uniformity by analyzing SUV of liver.Materials and Methods: Biograph mCT Flow Motion(Siemens) enables us to obtain image both by using FMT and SS. After injection of FDG with 3.5MBq/kg, we acquired PET image 2 hours later using FMT and SS. To avoid influence of time difference, patients ware divided two groups at random. One group was obtained image using SS first following FMT, and another group was FMT first following SS. All patients had no abnormality in the liver. ROI was settled in right lobe of the liver with 2cm in diameter. Total number of patients were 30 cases. SUVmax and SUVstd were measured and analyzed.Results: By using SS, SUVmax=2.77±0.46, SUVstd=0.248±0.058,by using FMT, SUVmax=2.61±0.45, SUVstd=0.208±0.062. Consequently, SUVmax of FMT is lower compared to SS about 5.7%, and SUVstd also lower in FMT.Conclusion: SUVmax of FMT is a little bit lower compared to that of SS. One of the reason may improvement of uniformity in FMT to reduce SUVstd.

18F-Fluorodeoxyglucose (18F-FDG) PET pulmonary imaging: comparative methodology in COPD patients

A. M. Fletcher[1], G. Choudhury[1], T. Clark[1], M. Connell[1], S. Fergusson[1], R. Rabinovich[1], N. Weir[1], B. Whitcher[2], I. Kilty[2], B. Vennart[2], E. J. R. van Beek[1], W. MacNee[1]; [1]University of Edinburgh, Edinburgh, UNITED KINGDOM, [2]Pfizer Worldwide Research and Development, Cambridge, MA, UNITED STATES.

Aim: To establish the optimum imaging and analysis protocol for FDG PET/CT imaging of lung inflammation in COPD patients in combination with quantitative CT analysis of emphysema. If successful the methodology could potentially be used to assess inflammation in the lungs to investigate the modulation of the FDG PET/CT signal as a biomarker of lung inflammation in drug development. Materials and Methods: Single-centre, exploratory, open-label study, of cross-sectional design to assess quantitative FDG PET-CT imaging in stable COPD patients. 20 patients with moderate-to-severe COPD underwent dynamic FDG PET imaging and high resolution CT (HRCT), combined with blood sampling to determine the localized plasma activity time curve twice 4 weeks apart. Images were analysed in the following manner: lung regions (lungs, thirds, lobes) were segmented on full inspiration HRCT and whole lung relaxed expiration attenuation correction (AC) CT using Apollo (VIDA Diagnostics, Coralville, USA). Two methods for removing emphysema were evaluated - eliminating areas below -950 HU on inspiration CT (standard for RA950) and removing the same relative area on relaxed expiration CT. Lung segmentation VOIs were transferred from full inspiration CT to PET by non-rigid registration of the full inspiration CT to the attenuation correction CT using ANTs(PICSL,UPenn). Arterial input functions (AIFs) were derived from either blood sampling or images. Finally the regional pulmonary FDG uptake was determined by SUV for 50-60 minutes. Patlak analysis of FDG time-activity curves from the lung VOIs (PMOD) generated estimates of slope (influx constant Ki) and intercept (initial volume of distribution). Results: Patlak intercept and SUV are correlated with lung density, and removing emphysema (particularly large contiguous regions) results in an increase in patlak intercept and SUV. There are issues with venous blood sampling, and image-derived AIFs when movement occurs. Conclusion: An optimum analysis protocol has now been determined. Methods of correcting for the density effect in quantitative PET lung studies require further investigation.

P060

Correlation of texture parameters with conventionally used semi quantitative parameter: standard uptake values, metabolic tumor volume and total lesion glycolysus in 18F-FDG PET/CT examination for breast cancer

N. Rana[1], K. Agrawal[1], D. Dhawan[2], A. Bhati[2], **B. Mittal**[1]; [1]Post-Grad. Inst. of Med. Education & Research, PGIMER, CHANDIGARH, INDIA, [2]Panjab University, CHANDIGARH, INDIA.

Background: Texture analysis (TA) is a set of computation methods that extract information from image on the basis of inter-relationships of pixels giving better insight of tumor heterogenity. Since metabolic heterogenity is a recognized characteristic of malignant tumor, TA is emerging as an important tool for evaluation of tumor uptake in PET studies. However, it needs to be established which indices could be of use and how they relate to conventionally used parameters. In our study we have classified texture parameters on the basis of their correlation with Standardized Uptake Values (SUVs), Metabolic Tumor Volume (MTV) and Total Lesion Glycolysis (TLG) in cases of breast tumor. Methods: Thirty-three patients with breast cancer who underwent whole-body PET/CT examination were included. TA in these patients was done using CGITA-Chang-Gung Image Texture Analysis toolbox, a software package based on MATLAB for texture analysis of molecular images having all built in functions for deriving different matrices like NGTDMs, GLRLMs, GLSZMs. PET/CT images in DICOM format of each patient were loaded on this software and sixty-nine texture parameters other than SUVs, MTV and TLG were derived by placing semi-automated ROI around active primary tumor. Conventional quantitative parameters like SUVmax, $SUV_{mean2.5}$, $MTV_{2.5}$, $TLG_{2.5}$ (threshold of SUV_{mean} = 2.5g/ml) and SUV_{mean40}, MTV_{40}, TLG_{40} (threshold of 40% of SUV_{max}) were also calculated for primary tumor using another semi-automated software for VOI placement to validate the SUVs value obtained using CGITA software. Linear correlation of each texture index with SUV_{max}, $SUV_{mean2.5}$, SUV_{mean40}, $MTV_{2.5}$, MTV_{40} and $TLG_{2.5}$, TLG_{40} was computed individually to study correlation between texture features and conventionally used quantitative parameters. Results: Texture parameters were classified as highly correlated (correlation coefficient $|r| \geq 0.90$), moderately correlated ($0.7 \geq |r| \leq 0.85$) and mildly correlated $|r| < 0.7$. Only three first order texture parameters were highly correlated to SUV_{max} and $SUV_{mean2.5}$. All texture parameters had $|r| < 0.50$ with SUV_{mean40}. Fourteen texture parameters were highly correlated and ninteen were moderately correlated

with $MTV_{2.5}$. Twenty-two were moderately correlated and none was highly correlated with MTV_{40}. Thirteen texture parameter were highly and twelve were moderately correlated with $TLG_{2.5}$. Only one texture parameter was moderately correlated with $TLG_{40.}$ Conclusion: Only few parameters had high correlation with SUV values, MTV_{40} and TLG_{40} indicating that a large number of texture parameters derived provide additional information. However level of significance of additional information provided by these texture parameters need to be tested further.

P061

Comparison of 3D texture features and metabolic parameters obtained from 18-F FDG-PET/CT images for evaluating tumor stage and subtype in non-small cell lung cancer

S. Karacavus[1], B. Yilmaz[2], O. Kayaalti[3], A. Tasdemir[4], E. Kaya[5], S. Icer[6], O. Ayyildiz[2], K. Eset[6], E. Vardareli[5], M. H. Asyali[7]; [1]Bozok University, School of Medicine, Department of Nuclear Medicine, Yozgat, TURKEY, [2]Abdullah Gul University, Department of Electrical and Electronics Engineering, Kayseri, TURKEY, [3]Erciyes University, Develi Hüseyin Şahin Vocational College, Department of Computer Technologies, Kayseri, TURKEY, [4]Kayseri Educational and Research Hospital, Department of Pathology, Kayseri, TURKEY, [5]Acıbadem University, School of Medicine, Department of Nuclear Medicine, İstanbul, TURKEY, [6]Erciyes University, Department of Biomedical Engineering, Kayseri, TURKEY, [7]7Department of Biomedical Engineering, Yıldız Technical University, İstanbul, TURKEY.

Aim: The purpose of this study was to compare three-dimensional (3D) texture features and metabolic parameters (maximum standardized uptake value (SUVmax, SUVmean), metabolic tumor volume (MTV), total lesion glycolysis (TLG) obtained from 18-F FDG-PET/CT images for evaluating tumor stage and subtype in non-small cell lung cancer (NSCLC). **Materials and methods**: Forty-two patients with NSCLC were included in this study. 3D texture features were extracted by first order statistics (FOS), gray-level co-occurrence matrix (GLCM), gray-level run-length matrix (GLRLM), and Laws' texture filters using custom MATLAB codes on 18-F FDG PET/CT images of all patients. The correlations between the 3D textural features and SUVmax, SUVmean, MTV, TLG, tumor TNM stage and subtype (adenocarcinoma (ADC) and squamous cell carcinoma (SqCCs)) were analyzed. **Results**: Significant moderate correlations were observed between MTV, TLG and GLRLM_GLN ($r=-0.5$; $p=0.002$), GLRLM_RLN ($r=0.7$; $p<0.001$) and Laws'_mean ($r=0.5$; $p=0.002$). While means of these texture features showed statistical significantly difference between TNM stage groups, there were no difference in the means of SUVmax, SUVmean, MTV and TLG values. SUVmax, SUVmean, GLCM_energy and homogeneity, GLRLM_SRLGE and LRLGE were notably different between tumor subtypes. **Conclusion**: Three-dimensional (3D) texture features of 18-F FDG images might be used as an objective tool to provide identifying tumor stage and subtype in NSCLC.

The role of SUV SPECT perfusion defect quantification of the lung as a predictor of severe cardiovascular events in a cohort of patients with congestive heart failure

W. He, W. Yu, J. Xi, W. Zhai; Huadong Hospital, Shanghai, CHINA.

Objectives : The aim of this study was to investigate the use of SUV SPECT to quantify lung perfusion defects in both non-CHF and CHF patients and to explore its correlation index as an outcome predictor for CHF patients. Methods : 30 patients were enrolled in the study. 17 CHF patients were followed for 16±5 mo (mean±SD) and 13 patients were a non-CHF control group. All patients underwent a lung perfusion scan, an independent diagnostic CT plus echocardiography. The lung perfusion scan was reconstructed using the software to convert the recorded counts per voxel into activity per unit volume to allow for SUV calculations. The diagnostic CT was co-registered with the SPECT perfusion scan in order to relate the perfusion function to anatomy. Using the software 'Hybrid 3D Lung Lobe Finder'. (HERMES MEDICAL SOLUTIONS)The lungs where further split semi-automatically into individual lobes by placing 10 to 15 points along each fissure. Using the computed anatomical volumes it was possible to record the total SUV and volume of each lung and lobe. The SUV difference between the CHF group and the control group were compared. Cardiac death, acute MI, unstable angina, and late revascularization (>3 mo) experienced by the patients during follow-up were defined as cardiac events. Multivariate Cox regression analysis was applied for cardiovascular events patients and different SUV index. Results : Preliminary results showed that there were no significant differences between the total lung SUV of the two groups. There were 10 patients (33.3%) who had cardiac events, including 2 acute MI, 3 late coronary artery bypass grafting, and 5 unstable angina pectoris during the follow-up. Conclusions : SUV SPECT perfusion defect quantification of the lung is a promising method for assessing pathology, physiology state and the rate of severe cardiovascular events in CHF patients.

Diagnostic accuracy of quantitative bone scintigraphy with artificial neural network in patients with breast cancer

A. Inaki, K. Nakajima, S. Watanabe, S. Kinuya; Kanazawa University Hospital, Kanazawa, JAPAN.

Bone scan index (BSI) calculated by artificial neural network (ANN) was developed as automatic and quantitative evaluation of bone metastasis. Some studies demonstrated the prognostic value of the BSI with regard to prostate cancer. The aim of this study was to assess the diagnostic value of the BSI in patients with breast cancer. MATERIALS AND METHODS We retrospectively evaluated 66 patients with breast cancer who underwent bone scintigraphy and FDG-PET with the intervals of less than 4 weeks between both examinations. RESULTS The BSI with and without bone metastasis were 1.57 ± 1.73 and 0.15 ± 0.34, and there were significant differences between 2 groups ($p < 0.001$). Mean follow-up period was 1535 ± 749 days and the number of patients of no evidence of disease (NED), alive with disease (AWD) and died of disease (DOD) were 28, 16 and 20, respectively. The sensitivity and the specificity of the BSI was 86.4% and 81.8% with a cut-off value of 0.185. The Kaplan-Meyer curve showed that the patients with higher level of the BSI had significantly lower prognosis than with lower level of the BSI. In the Cox proportional hazards model, the BSI was a good prognostic factor with a hazard ratio of 1.24 (1.13 - 1.36, 95%CI). CONCLUSION The BSI will play a important role on not only detecting bone metastasis but also predicting prognosis in patients with breast cancer.

Cerenkov Radiators for Preclinical Optical Imaging

C. R. Gigliotti, L. Altabella, A. E. Spinelli; San Raffaele Scientific Institute, Milano, ITALY.

Aim: Cerenkov luminescence imaging (CLI) is a molecular imaging technique that combines nuclear and optical imaging, detecting Cerenkov radiation produced by beta-emitting radionuclides. Due to the faint emission, the use of a Cerenkov radiator (CR) can be useful to enhance the detected signal and consequently reducing the acquisition time. Since the energy threshold for Cerenkov production (CP) decreases increasing the medium refractive index (RI), the first approach is the use of high RI material to exploit the beta particles exiting from the tissue. Nevertheless, in the low energy field, other parameters have to be taken into account for the optimization of CLI. The goal of this work is to investigate the efficiency of different materials by studying the effect of their characteristics on CP. Methods: We performed MC simulations using GAMOS plug-in for GEANT4. As a proof of principle, we considered mouse muscle tissue in which, at different depths, is placed a low, medium or high energy beta-emitter used in nuclear medicine (NM) and a CR of variable thickness is superimposed to the tissue. In order to investigate the role of the material characteristics on CP, we simulated PMMA and high RI transparent ceramic. The dependence of RI and of density on CP was also investigates by slightly varying them from the true values. Results and conclusion: The higher percentage of exiting photons is observed for low density ceramic, with the same RI of the real ceramic, which shows nearly half of the efficiency, while the PMMA with a lower RI shows a halfway efficiency. The results show that the RI of a material is not the crucial parameter that affects the efficiency of CR, whereas the density seems to be the one that mainly affects the CR. We believe that such an effect is due to the way the electrons lose energy in matter that influences the change of particle velocity. Comparing the results obtained with different β-emitters, we observe the major production gain for the 32P source. We conclude that the ideal material for a CR optimized to CLI has low density and high RI and that the major enhancement of the signal is expected for medium energy β-emitter. Further investigation in order to take into account the CR effects on spatial resolution are now under implementation.

P065

Striatum specific F-18 FP-CIT analysis in Parkinson disease

J. S. Oh[1], **I. Lee**[1,2], H. Moon[1], J. Kim[2], M. Oh[1], J. Kim[1]; [1]Department of Nuclear Medicine, Asan Medical Center, University of Ulsan College of Medicine, Seoul, KOREA, REPUBLIC OF, [2]Department of Nuclear Engineering & Radiologic Science, College of Health Science, Korea University, Seoul, KOREA, REPUBLIC OF.

Aim: Conventional volume of interests (VOIs) analysis of F-18 FP-CIT PET usually employed conventional spatial normalization using whole brain PET images. Due to VOI mismatch caused by spatial normalization error, researchers needed to manually modify the VOIs for more accurate analysis, in turn, lead to labor intensiveness and inter-observer reliability issue caused by manual VOI adjustment. To better localize the VOIs, we suggest new spatial normalization method called striatum-specific SPM (SSPM) using a mask encompassing striatum and midbrain.

Materials and methods: One hundred forty subjects (23 normal controls (NC), 117 patients with Parkinson disease (PD))

underwent F-18 FP-CIT PET. Image acquisition was started 3 h after intravenous injection of 18F-FP-CIT (185 MBq). Spatial normalization was conducted using SPM8 and VOI analysis was conducted using our in-house FP-CIT PET and VOI templates. Then, we applied spherical mask with a 28 voxel (5.6cm) radius to exclude regions other than midbrain/striatum on not only FP-CIT template but also the resulting individual spatially-normalized FP-CIT PET images.An iterative spatial normalization using study specific template (SST) was conducted. Finally, mean uptake values of 12 striatal VOI templates (bilateral ventral striatum [VS], anterior caudate [AC], posterior caudate, anterior putamen, posterior putamen [PP], and ventral putamen [VP]) and that of reference region (i.e., occipital lobe) were estimated automatically by our in house software called ANTIQUE. For the ground-truth information of mean VOI uptake and VOI location, one of us (IL) manually adjusted the VOI under supervision of 20 year experiencedboard-certified nuclear medicine physician (JK). We compared FP-CIT SSPM method and conventional method in terms of VOI uptake % error and VOI location accuracy. VOI uptake % error values were calculated for each VOI using (automatic method-based uptake - manual method-based uptake)/(manual method-based uptake) x 100 (%). VOI location inaccuracy was estimated for each VOI using the mean distance between automatic VOI and manually-adjusted VOI.

Results: Except bilateral AC in NCs, the uptake % error between SSPM auto and SSPM manual is smaller than that between whole brain manual and SSPM manual ($p<0.001$) in both groups.In both group, all VOIs but VP of PD (a relatively small VOI) showed significantly decreased VOI displacement ($p<0.05$) by FP-CIT SSPM than conventional method.

Conclusion: SSPM outperform than conventional spatial normalization-based approach in terms of significantly less % error and more accurate VOI location. We suggest our SSPM may serve as a new automatic VOI analysis method of FP-CIT PET.

P066

Quantitative Evaluation of Scattered Photons in a Myocardial Pinhole SPECT Imaging

K. Ogawa, N. Aitani, Y. Hemuki; Hosei University, Tokyo, JAPAN.

Aim: Multi-pinhole collimators have been recently used in myocardial SPECT systems. Myocardial imaging with pinhole collimators may acquire many undesirable photons such as primary and scattered photons originating in the liver. This study aimed to quantify the effect of these undesirable photons. Materials and Methods: The DMCAT phantom was used in Monte Carlo simulations. The size of the phantom was 128 x 128 x 128 voxels and the size of a voxel was 2.5 x 2.5 x 2.5 mm^3. We emitted photons with an energy of 140 keV from the liver, myocardium and blood regions, and the numbers of photons were 0.8, 0.8, and 0.05 Mega/voxel, respectively. As a reference we also simulated the case without liver activity. The distance between the center of the phantom and pinhole was 18 cm and that between the pinhole and NaI detector was 9.9 cm. The diameter of a pinhole was 3 mm and the aperture angle of the pinhole collimator was 60 degrees. We rotated the pinhole detector system around the DMCAT phantom and the number of projection data was 360. The energy resolution of the detector was 10 % FWHM at 140 keV and we set an energy window with a width of 20 %. The reconstruction of an image was performed with the OS-EM method. We assumed that all regions inside the phantom except for the lungs consisted of water, and attenuation correction was performed in the process of image reconstruction. We evaluated the effect of scattered photons with a contrast ratio of the myocardial area between the conditions with and without the liver activities. Results: The myocardial images were blurred with scattered photons originating in the liver. The contrast ratios of reconstructed activities in the myocardial area to the blood area were 0.65 (without liver activities) and 0.43 (with liver activities). Conclusions: The scattered photons originating in the liver affect the quality of reconstructed myocardial images, making it very important that the scattered photons in the pinhole SPECT image be considered.

Image noise estimation using sub-reconstructions of clinical Whole Body PET/CT data

A. K. Krizsan[1], A. Forgacs[2], G. K. Nagy[1], M. Szolik[1], M. Dahlbom[3], L. Balkay[1]; [1]University of Debrecen, Medical Center, Department of Nuclear Medicine, Debrecen, HUNGARY, [2]ScanoMed Nuclear Medicine Centers, Debrecen, HUNGARY, [3]University of California at Los Angeles, David Geffen School of Medicine, Department of Molecular and Medical Pharmacology, Ahmanson Biological Imaging Center, Los Angeles, CA, UNITED STATES.

Aim: The estimation of image noise defined as pixel-wise Signal-to-Noise on Whole Body PET images can be routinely performed on series of phantom scan image data. Simply Region of Interests' (ROIs) can be used to calculate the Signal (as Mean) and the Noise (as Standard Deviation) values. However, in case of a clinical patient scan the activity distribution is heterogeneous and the use of multiple scans is typically limited. A new method we propose to estimate pixel-wise noise of clinical PET images from a single raw data with series of sub-reconstructions.

Materials and Methods: A uniform cylindrical phantom set with increasing diameter and an anthropomorphic thorso phantom were scanned with 18F-FDG using clinical scanning protocols, the latter to mimic human non-uniform imaging conditions. Furthermore, Whole Body PET image data of two patients with elongated scan times were involved in the investigation. From the single list mode files sub-reconstruction series were generated with different time durations and using these image data, noise was estimated pixel-wise with linear regression interpolation. As a gold standard, we used extended PET scans in all cases and determining the image noise pixel-wise by using image sets of the clinical routine scan durations.
Results: The Standard Deviation/Mean data showed qualitative similarities in terms of image patterns. Using ROI analysis the difference between the conventional and new estimation method of image noise remained under 10% in case of the uniform cylinder and under 15% for both the anthropomorphic phantom and patient studies even in case of using post filtering on the images. This good correlation suggests further considerations on optimizations of the method and extending on a larger population of patient data.
Conclusion: The preliminary results indicate that this new method could be used for pixel-wise noise estimation of clinical PET scans without the need for repeated scans.

P068

Looking for physiological factors affecting texture analysis on clinical PET… with texture standardization in mind!

J. Cortes-Rodicio, G. Sanchez-Merino, R. Lope-Lope, J. Ruiz-Pomar, T. Martin-Gonzalez, M. Garcia-Fidalgo; Osakidetza, Vitoria-Gasteiz, SPAIN.

INTRODUCTION AND OBJETIVES: Texture parameters are important features commonly used for pattern recognition, image classification and, more recently in the field of "radiomics", where more useful information might be extracted from medical images. Anyway, texture quantification is affected by many technical and physiological factors. The purpose of this work is to study the texture features of non-pathological livers as a function of the anatomical and physiological properties of the patients undergoing PET studies.
METHODS AND MATERIALS: The data for 15 patients showing non-pathological liver were acquired on a Philips GEMINI TF PET/CT. Patients were injected with a linear FDG dose regime of 2.5MBq/kg after 6h of fasting and acquired after 60 min at rest. Raw PET data were reconstructed using a BLOB-OS reconstruction protocol with attenuation correction resulting a grid size of 4mm. Anatomical and physiological features like patient's weight, height, body mass index, liver volume and glucose level in blood, were also registered. A liver covering ROI were delineated in each patient. To avoid variability due to reconstruction protocols and activity concentration, only texture features that showed to be robust on a previous study with phantoms were analyzed using Chang Gung Image Texture Analysis toolbox for MatLab. Those were entropy (Haralik-1973, Sun-1983, Horng-2002); short-run-emphasis and run-percentage (Loh-1988); the homogeneity, intensity, inverse-difference-moment and code-entropy (Horng-2002); and short-zone-emphasis and zone-percentage (Thibault-2009). Finally, a multivariate Pearson correlation analysis was performed using StatGraphics Centurion XVI software.
RESULTS There is a high statistical correlation between liver volume and entropy (p-value<<0.05). Entropy feature is, indeed, correlated (p-value<0.05) with all patient's parameters, except body mass index. The only textural features that do not seem to be correlated (p-value>0.05) with any of the anatomical or physiological parameters are run-percentage (Loh-1988), short-zone-emphasis (Thibault-2009) and intensity (Horng-2002), making them suitable for quantitative textural analysis.
CONCLUSIONS: Textural feature analysis allow for a deeper knowledge of tumor uptake in 18F-FDG PET/CT studies but they present an intrinsic variability due to technical and physiological factors that should be taken into account. Most of the textural features analyzed are correlated with these factors and are, therefore, more prone to errors in quantifying changes or classifying patients. Only three of them seemed to be suitable for this purpose. Even though, further studies should be carried out in order to improve the statistical power of the analysis.

P069

Repeat (R)-[11C]PK11195 brain PET scans in glioma

M. Bauer[1,2], Z. Su[1], F. Roncaroli[3], A. Gerhard[1], F. Turkheimer[4], K. Herholz[1], R. Hinz[1]; [1]University of Manchester, Manchester, UNITED KINGDOM, [2]Medical University of Vienna, Vienna, AUSTRIA, [3]Imperial College London, London, UNITED KINGDOM, [4]King's College London, London, UNITED KINGDOM.

Aim: The analysis of human brain PET scans with tracers binding to the 18-kDa mitochondrial translocator protein (TSPO) is hampered by the absence of an anatomical brain region free of specific binding. We previously reported a comparison between two referencing approaches, *cerebellar* grey matter (GM) reference input function and supervised cluster analysis with six classes (SVCA6)[1], in glioma patients scanned with (*R*)-[^{11}*C*]*PK11195*[2]. Here we compare these two input functions in repeat scans. Materials and Methods: Three patients with clinically stable glioma (WHO grade: subject: 1 III, subject 2: II, subject 3: II) were

scanned twice with (*R*)-[^{11}*C*]*PK11195, at 23, 6 and 8 months after the initial PET scan. Parametric maps of binding potential* (*BPND*) *were generated with the simplified reference tissue model using either a cerebellar GM or a SVCA6 input function. Regional BPND differences* ΔBPND = $BPND_{scan2}$ - $BPND_{scan1}$ *were calculated in the following regions*: *frontal*, *temporal*, *parietal*, *occipital lobe*, *thalamus*, *hippocampus and tumour cold region. T-tests were performed to assess statistical significance*. Results: BPND with SVCA6 input function were systematically smaller than those with cerebellar GM input function (p=0.0317, paired t-test). ΔBPND derived with SVCA6 were significantly larger than those with cerebellar GM input function (p=0.0002, paired t-test). One-sample t-tests performed on the regional ΔBPND for the three patients revealed no difference with the cerebellar GM input function (p_1=0.0822, p_2=0.3595, p_3=0.6793) but statistically significant increases with SVCA6 (p_1= 0.0003, p_2=0.0055, p_3<0.0001). Conclusion: Of the two reference tissue input functions considered here, only the data-led approach SVCA6 reported statistically significant changes in BPND in the follow up scans. The cerebellum GM as an anatomically defined reference region failed to reveal changes of significance in BPND in other parts of the brain in conjunction with the simplified reference tissue model. Segmentation gross tumor volume on positron emission tomography by a method combined with numerical approximation and local gradient _ an animal study

Y. CHEN; Quanzhou First Hospital of Fujian Medical University, quanzhou, CHINA.

Segmentation gross tumor volume on positron emission tomography by a method combined with numerical approximation and local gradient—an animal studyPurpose: A scheme, named SUV_Shape 2.0, drawing gross tumor volume (GTV) on PET images was made by a numerical approximation method combined with maximal local gradient, and evaluated during this study.Methods: Five rabbits implanted VX2 squamous carcinomas kept fasting at least 4h before [18F]-FDG imaging. 37MBq [18F]-FDG was administrated following their blood glucose level detection. Their 3D PET data were acquired at 10min-120min after injection by a PET/CT scanner (Discovery ST8, GE Healthcare, USA). Euthanasia was done in the next 24h. Each VX2 tumors was resected, and its maximal perpendicular diameters were measured by a caliper. Its volume was computed following the equation of spheroid volume, SUV_Shape, and SUV_Shape 2.0, then labeled as GTVt, GTVs1, and GTVs2, respectively. The Spearman's rho and paired t-test among GTVt, GTVs1 and GTVs2 were done.Results: Eight VX2 tumor nodes or masses were included in this study. Their GTVt were 29.26, 0.41, 4.22, 24.15, 21.44, 1.26, 0.21, and 1.63mL. Their tumor-nontumor ratio were 16.1, 3.7, 1.63, 16,1, 4.65, 6.16, 4.58, and 1.5. The relationship between GTVt and GTVs1 was significant (Spearman's rho=0.976, P<0.01), and they were not significant difference (t=1.43, P=0.195). The correlation between GTVt and GTVs2 was significant (Spearman's rho=0.929, P<0.01), and they were not significantly different (t=0.088, P=0.933). The relation between GTVs1 and GTVs2 was significant (Spearman's rho=0.952, P<0.01), and they were not significant difference (t=-1.42, P=0.199). The GTV of VX2 tumor masses (2/3) were obviously underestimated by SUV_Shape1 (GTVs1 vs GTVt: 14.95 vs 29.26 mL, 23.52 vs 24.15mL, and 13.40 vs 21.44mL); while they were partly corrected by SUV_Shape2.0 (GTVs2 vs GTVt: 27.50 vs 29.26 mL, 31.6 vs 24.15mL, 18.5 vs 21.44 mL). However, the difference between GTVs1 and GTVt among VX2 tumor nodes were smaller than the difference between GTVs2 and GTVt.Conclusions: The SUV_Shape 2.0 scheme was good for tumor masses delineation, while SUV_Shape was good for tumor nodes outline.Key words: gross tumor volume; segmentation; positron emission tomography

P071

Computer-aided Diagnosis System to Assess Metastatic Disease Presence and Evolution

I. V. Popa[1], I. Grierosu[1,2], A. Statescu[1], M. Gutu[1,2], R. Gherasim[1], S. Bilha[1], R. Olaru[1], C. Cijevschi-Prelipcean[1,2], C. Mihai[1,2], L. Ionescu[1,2], C. Vulpoi[1,2], C. Luca[1,2], C. Stefanescu[1,2]; [1]"St. Spiridon" Hospital, Iasi, ROMANIA, [2]Medicine Faculty, "Grigore T. Popa" University of Medicine and Pharmacy, Iasi, ROMANIA.

AIMS: Our aim was to develop a computer-aided diagnosis (CAD) system able to evaluate the presence and quantitatively assess the evolution of the metastatatic disease (MTSD) on repeated radiotracer scans.MATERIAL and METHODS: We worked on ^{99m}Tc HDP whole body images of MTSD. The method was developed using Matlab® and has three steps. The first, preprocessing step, brings scan images at the same contrast level. The second, processing step, identifies areas of interest using the *watershed method* improved by a series of accessory methods. The third, postprocessing step, is about manually eliminating hyperfixing areas, automatically encircled, that are certainly not metastases (like the joints images etc.). On the final image, several descriptive quantitative parameters (both global and local) were calculated. The global parameters were: ratio between the area occupied by MTS and entire skeleton surface (RM) and the MTS number (NM). The local parameters, in order to characterize each lesion in

evolution, were: region gravity center coordinates, area, width, height, maximum intensity pixel value, mean value and standard deviation, calculated for both anterior and posterior incidences.RESULTS: We exemplified the results obtained for a MTSD patient in evolution, for the first bone scan and for the repeated bone scan, after three years. For the first image, anterior incidence, we obtained RM = 15.28% and NM = 41. For the image in evolution we got RM = 16.01% and NM = 42. Regarding the local descriptors, as an example, one hyperfixing metastasis has an area of 24 pixels at first examination and a 70 pixels area at the second. Also, it can be seen how some lesions have disappeared, some have emerged, some have grown in size and some others decreased in size. The descriptors are saved in the patient history archive, in order to compare them with the same descriptors from subsequent examinations of the same patient. The system automatically represents graphically both global and local values. CONCLUSIONS: Our CAD system proved to be efficient for quantitative assessment of MTSD in evolution on whole-body scans, but could also be applied in other scan types - for example, in the case of MTSD that uptake other radiotracers, ^{99m}Tc MIBI or ^{131}I. This system represents an automated solution capable of helping the doctor in identifying metastases and in calculating quantitative parameters in evolution, ensuring both objectivity and rapidity in the MTSD evaluation.

Practical measures of dynamic 18 FDG time-activiy curves.

M. Tuncel, O. Kupik, P. Kiratli, B. Erbas; Hacettepe University, Ankara, TURKEY.

AIM: Kinetic measures of dynamic 18 FDG PET/CT studies have been proposed being superior compared to static measures such as SUVmax values. Dynamic parameters have been used in the early assessment of therapy response in oncological patients. However, complexity of kinetic analysis may limit its application in the rutine clinical studies. Therefore, this study was planned to analyze the dynamic data in an easy and practical way. MATERIALS and METHODS: Dynamic images were recorded following i.v. injection of 18 FDG. Study group had 30 patients. Time-activity curves were obtained from regions of interest drawn on the tumoral tissue and on the aortic arc as an input function. Using, lineer regression analysis of time-activity curves, slope (SL) values were calculated for several time intervals, i.e, 0-2 min (SL2), 0-5. min. (SL5), 0-10 min.(SL10), 0-30. min. (SL30), respectively. Similarly, SUVmax values for 2nd min (SUV2), 5th min (SUV5), 10th min (SUV10), and 30th min. (SUV30) were measured. For the first 2 minutes, data were added and SUVmean (SUV2mean), SULpeak (SUL2peak), perfusion volume (Per2V) and total lesion glycolysis (TLG2) values were calculated. For comparison, 2-tissue compartmental analysis was performed and K1-k4 values were measured. In addition, Ki values were calculated. Two-compartmental parameters were compared to the other measured parameters. RESULTS: SL2 had correlation with K1, whereas SL5 (r=0.64, p=0.0001), SL10 (r=0.76, p=0.0001), and SL30 (r=0.85, p=0.0001), values showed increasing correlation coeffiencient with Ki values. K3 values had correlation with SL5 (r=0.38, p=0.04), SUV10 (r=0.54, p=0.03), and SL30 (r=0.66, p=0.0001) values. SUV2 showed a good correlation with K1 (r=0.83, p=0.0001). Correlation between SUV5 (r=0.62, p=0.0001), SUV10 (r=0.44, p=0.0001), SUV30 (r=0.42, p=0.0001), and K1 was decreasing with time. SUV values were also correlated with Ki values (SUV5 r=0.65, p=0.0001, SUV10 r=0.85, p=0.0001, SUV30 r=0.88, p=0.0001), except SUV2 value. SUV2mean, SUL2peak, Per2V and TLG2 values were correlated with K1 and K2. SUL2peak and SUV2mean had highest correlation coefficient with K1 (r=0,93, p=0.0001, and r=0.88, p=0.0001, respectively). CONCLUSION: Slope and SUV measurements of dynamic curves showed good correlation with 2-compartmental analysis parameters. Those measures can be easily applied and give information about the 18FDG dynamics. Further studies are needed to explore its clinical relevance.

Early X-Ray CT Radiomic Identification of Lung Tissue Harm Origins in Mice

D. Mathe[1], F. Budan[1], C. Korom[2], D. Veres[3], K. Szigeti[3]; [1]CROmed Ltd, Budapest, HUNGARY, [2]Dept. Radiology Semmelweis University Budapest, Budapest, HUNGARY, [3]Dept. Biophysics and Radiation Biology Semmelweis University, Budapest, HUNGARY.

Introduction. Lung diseases (resulting from air pollution) require a widely accessible method for risk estimation and early diagnosis to ensure proper and responsive treatment. Radiomic fractal dimension-based analysis of X-ray computed tomography (CT) attenuation pattern in chest voxels of mice exposed to different air polluting agents was performed to model disease establish differential diagnosis and discern sources of harm to lung tissue. To model different types of air pollution, the following Balb/CBYJ mouse groups were exposed: cigarette smoke combined with ozone, sulfur dioxide gas, and a control. Two weeks after exposure, the frequency distributions of image voxel attenuation data were evaluated. Specific cut-off ranges were defined to group voxels by attenuation. Each cut-off ranges were binarized and their spatial pattern was associated with calculated fractal dimension, then abstracted by the fractal dimension-cut-off range mathematical function. Each cut-off range versus fractal dimension function plot was

found to contain two distinctive Gaussian curves. The ratios of the Gaussian curve parameters distinguished the three exposure groups statistically significantly. A new radiomic evaluation method was established based on analysis of CT voxel datadistribution and fractal dimension of the resulting lung CT data segments. The resulting attenuation values of voxels corresponded to specific tissues as well as the calculatedparameters to the inflammation- and mucuspatterns to air pollution exposures. Most likely those specific attenuation patterns calculated with our method could diagnose and monitorcertain lung diseases, such as chronic obstructive pulmonary disease (COPD), asthma, tuberculosis or lung carcinomas.

development of metabolic tumor volume measurement based on suvpeak

K. Koyama[1,2], T. Mitsumoto[1], K. Inoue[2], K. Tsuda[3], K. Kotaka[1], K. Yoshikawa[1], K. Hatano[1], M. Fukushi[2]; [1]Tokyo Bay Advance Imaging & Radiation Oncology Clinic-MAKUHARI, Chiba, JAPAN, [2]Tokyo Metropolitan University, Tokyo, JAPAN, [3]Tsukuba International University, Ibaraki, JAPAN.

Aim: FDG-PET/CT allows determination of metabolic tumor volume (MTV) and total lesion glycolysis(TLG) which provides prognostic and predictive value in oncology. MTV is commonly measured based on maximum standard uptake value (SUVmax). However SUVmax is affected by noise and statistical error. To achieve stabile MTV measurement we developed a new method based on peak standard uptake value (SUVpeak). Materials and methods: The Discovery 710 PET/CT device was used in this study. The participants comprised 13 patients with lung lesions (lesion size 24.5 ± 10.3 mm, lesion volume 6.6 ± 5.6 ml). A volume of interest (VOI) including the tumor threshold by 40%, 42%, 50%, 60%, 70% and 80% of SUVpeak within the VOI was used to measure MTV. MTV errors were assessed using CT tumor volume as a standard and compared with conventional methods based on SUVmax threshold by 42% and 50%. Results and conclusion: The MTV error base on SUVpeak40% was -0.54±3.0 (95% confidence interval : -2.4 - 1.3, range: 11.8) ml and the best agreement with CT volume. The MTV error based on SUVmax42% and SUVmax50%was -3.4±3.3 ml (95% confidence interval : -5.4 - -1.3, range: 12.3) and -4.3±4.0 ml (95% confidence interval : -6.9 - -1.8, range: 14.8). The MTV based on SUVpeak40%, SUVpeak42% and SUVpeak50% were significantly improved as compared with SUVmax42% (One-Way Repeated Measures ANOVA $P < 0.05$). New method based on SUVpeak reduced MTV error and statistical error. It was shown that new method based on SUVpeak reduced MTV error and was achieved stabile MTV measurement.

P075

Analysis of Inter-Detector Scattering in PET with Various Energy Window Settings

K. S. Chuang, Z. J. Wei, H. H. Lin; National Tsing-Hua University, Hsin-Chu, TAIWAN.

[**Aim**] In conventional positron emission tomography (PET) an energy window of [425 650] keV is commonly used. A large amount of useful information is lost due to the partial deposition of energy of the annihilation gamma in the detector generating inter-detector scattering (IDS) triple events in PET. These events are caused by one of the annihilation photons deposits energy in more than one detector. IDS are not recorded because the events are not in the energy window. Some of these events are recoverable, i.e. the correct line of responses (LOR) can be identified and added to the data stream. It is possible to employ a wider energy window to include and recover the IDS and increase the system sensitivity.
[**Materials and Methods**] However, several factors cause the degrading of the image quality when a lower threshold of energy window is used. (1) The number of random events increases. This can be corrected using traditional delayed window techniques but with the cost of increasing noise in the data. (2) The number of multiple scattering events becomes significant. The conventional scatter correction technique i.e. single scatter simulation (SSS) might fail. (3) The IDS events produce three ambiguous LORs. Techniques can be developed to identify correct LOR. Wrongfully recovery of the IDS events will blur the image.
[**Results**] A NURBS-based cardiac-torso (NCAT) phantom was simulated at various activity levels. Preliminary results show that IDS remains as a constant percentage at the range of activity tested while the random triple increases with the increase of activity. We will investigate the effects on image quality and sensitivity at various energy window settings based on Monte Carlo simulation. Noise equivalent count rate (NECR), spatial resolution, coefficient of variance, and

coefficient of recovery will be used to gauge the effects of energy window setting on image quality.
[**Conclusion**] A best energy window that is a tradeoff between image quality and system sensitivity can be determined from this study.

P076

Optimisation of automatic image segmentation for tumour volume determination in 18F-FDG PET/CT for patients with liver lesions

D. Ruiz, E. Kalogianni, B. Corcoran, A. Eccles, N. Mulholland, G. Vivian; King's College Hospital NHS Foundation Trust, London, UNITED KINGDOM.

Aim: There is a need for the optimisation of thresholding used for automatic PET image segmentation for lesions that lie within organs with variable background activity such as the liver. The aim of this study was to determine suitable threshold levels for use in measuring tumour volume and uptake values for assessment of respiratory gated PET for imaging liver lesions.Method: Images of a PET NEMA Image Quality phantom containing 6 spheres with volumes ranging from 0.5 - 26.5 ml were obtained using a GE Discovery 710 PET/CT scanner. The phantom was filled with 18F activity corresponding to that clinically observed in liver lesions and normal liver background. The background activity concentration was kept constant at approximately 7 kBq/ml, while the activity of the spheres was varied to obtain lesion-to-background (L/B) ratios of 1.5, 2.3, 2.7, 3.2, 3.6 and 4.4. The optimum threshold level for image segmentation was determined from phantom images by selecting that which resulted in the minimum difference between the actual and measured volume for each sphere size and L/B ratio.Results: Analysis of phantom images showed that for spheres with a volume greater than 5 ml the optimum threshold for image segmentation begins to converge for all except the lowest L/B ratios of 1.5 and 2.3. The optimum threshold was found to depend on the L/B ratio and ranged from 49 % to 95 % for the 26.6 ml sphere with L/B = 4.4 and 0.5 ml sphere with L/B = 2.3 respectively. Generally, the optimum threshold value increased with decreasing L/B ratio. The three smallest spheres were not visible in images of the phantom with the lowest L/B ratio.Conclusion: The use of appropriate threshold levels for PET image segmentation is essential for the accurate definition of lesion volume and quantitation. While more sophisticated image segmentation algorithms are required for applications such as radiotherapy treatment planning and dosimetry calculations, these results will improve the accuracy of liver lesion volume determination for evaluation of PET imaging techniques. Further work is required to validate this method for use on patient images, and implement it for assessment of respiratory gated PET.

P077

Aspects on quantification and detectability in 111In SPECT/CT and 68Ga PET/CT images of neuroendocrine tumours

A. Stenvall[1], E. Mattsson[1], E. Larsson[1], T. Ohlsson[1], C. Hindorf[1], **L. Jonsson**[2]; [1]Radiation Physics, Skane University Hospital, Lund, SWEDEN, [2]Medical Radiation Physics, Lund University, Lund, SWEDEN.

AimNuclear medicine imaging of neuroendocrine tumors (NET) is performed either by SPECT/CT imaging, using 111In-octreotide or by PET/CT imaging using 68Ga-radiolabelled somatostatin analogs. The two imaging techniques will give different image quality and thereby different detection thresholds for tumours, depending on size and activity uptake. Often a subjective evaluation is performed to compare tumour uptake with the activity uptake in the liver to decide whether the patient could be eligible for radionuclide therapy.The aim of this study was to evaluate the image quality for 111In SPECT/CT and 68Ga PET/CT imaging, i.e. the smallest volume possible to visualize for different source-to-background activity ratios. The accuracy of quantification of lesion volume and activity was also investigated to develop an objective evaluation for radionuclide therapy eligibility.Materials and methodsThe phantom study was performed using the IEC Body Phantom with six hot spheres having inner diameters of 10, 13, 17, 22, 28, and 37 mm, filled with either 68Ga or 111In with sphere-to-background (S/B) ratios of no background activity, 10:1, 5:1, 2.5:1, 1.67:1 and 1.25:1. These S/B ratios were chosen as representative values of tumour-to-background ratios in patients. Activity ratios of 1.25:1 and 2.5:1 are clinically found for lesions close to liver and spleen. Clinical acquisition and reconstruction protocols were applied. Line profiles were drawn to evaluate the smallest

detectable volume within a given S/B ratio. Recovery curves based on threshold segmentation were obtained for all combinations of S/B ratios and sphere diameters, allowing for quantification.ResultsThe line profiles showed that the 10 mm sphere was not possible to detect in SPECT images. It was detectable in PET images for S/B ratios of 2.5:1. In a background corresponding to the activity uptake in the liver (S/B 2.5:1 and 1.25:1) spheres larger than 22-37mm were detectable in the 111In-SPECT images and spheres larger than 13-22mm were detectable in the 68Ga-PET images.The maximum activity concentration was accurately quantified for spheres larger than 22mm in the PET images however the quantification was impaired by sphere size and background activity.ConclusionIt was not possible to detect the 10mm sphere in any of the SPECT images. In a background corresponding to the activity uptake in the liver, spheres larger than approximately 30mm were visible in the 111In-SPECT images and spheres larger than approximately 17mm were visible in the 68Ga-PET images. Sphere diameter and background activity strongly affect the possibility of a correct quantification.

Optimisation of Y-90 post-SIRT PET imaging on GE Discovery systems

L. M. Rowley, D. R. McGowan, K. M. Bradley, A. Hallam; Oxford University Hospitals NHS Trust, Oxford, UNITED KINGDOM.

Aim: To optimise image reconstruction parameters for 90Y using phantoms and patients on our GE Discovery 690 and 710 PET-CT scanners for both standard OSEM and a new Bayesian penalised likelihood reconstruction (BPL) algorithm (Q.Clear, GE Healthcare, Milwaukee, USA). Methods: Following radioembolisation for the treatment of liver tumours using 90Y, users may choose to perform either Bremsstrahlung imaging or PET-CT, to visualise the deposition of the activity and note any extra-hepatic activity. The BPL reconstruction has beta, a noise suppression term as the only user-input variable, unlike OSEM which has iterations, subsets, and filters. BPL includes point spread function (PSF) modelling (SharpIR) as part of the reconstruction. A NEMA NU-2 Image Quality (IQ) phantom was filled with 4.2GBq 90Y, with a sphere to background ratio of 8:1 in each of the six spheres. This was scanned over 9 nights on the GE Discovery 710 PET-CT scanner. Data was rebinned into 15 minute frames and reconstructed using both time of flight (ToF) BPL and ToF OSEM. For BPL this was using beta values 1-10,000. For OSEM this was using 1-5 iterations, 8-32 subsets, 0-10 mm Gaussian filter and with SharpIR both on and off. Contrast recovery (CR) and background variability (BV) were calculated as per the NEMA NU 2-2007 standard. A subset of the best performing reconstructions parameters for both BPL and OSEM were applied to ten patient images. Each set of patient images were ranked by an experienced radiologist blinded to the reconstruction parameters. Results: From the best performing phantom BPL reconstructions (beta 2,000-4,000) the patient images with a beta of 3,000 ranked highest. For this beta the CR of the 37mm sphere was 81% ±3.9% and BV 7% ± 1.5% for a total phantom activity of 2.7GBq, and CR 74% ±8% and BV 19% ±4% for a total image activity of 0.9GBq. These values were higher than the optimised OSEM reconstruction. The beta value was appropriate over the range of activities scanned (4.2GBq - 0.47GBq). Dead time was apparent at activities above 3.5GBq with contrast recoveries reduced by 23% at 4.2GBq. Clinical images using BPL with a beta of 3,000 appeared superior to optimised OSEM and Bremsstrahlung images. Conclusion: The use of BPL with 90Y post-SIRT images achieves an increase in contrast recovery and decreased background variability compared to OSEM.

P079

Analysis of Radiation-Induced Liver Disease (RILD) and Evaluation of Relationship Between Therapeutic Activity and Liver Clearance(C) Rate with Tc-99m-Mebrofenin(M) in Y-90 Microspheres Treatment(MT)

H. Tanyildizi, M. Abuqbeitah, L. Kabasakal, M. Demir; Istanbul University, Istanbul, TURKEY.

Objectives : Whole liver radiation has modest benefit in treatment of unresectable hepatic metastases but the radiation doses must keep in control. In this study, we aimed to calculate amount of max permissible activity (MPA) and critical organ doses with MIRD, to evaluate tumour doses for treatment response and whole liver doses for RILD and to find optimal liver function test additionally. Methods : This study includes 29 patients who attended our nuclear medicine department suffering from Y-90 MT. 10 mCi Tc-99m MAA was applied to patients for dosimetry. After injection, whole body SPECT/CT images were taken in one hour. The min therapeutic tumour dose is on the point of being 120 Gy1, the amount of MPAs were calculated with MIRD considering volumetric tumour/liver rate. A sub-working group was created with 11 patients randomly and liver C rate with Tc-99m-M was calculated according to Ekman formalism2. Results : The volumetric tumour/liver rates were found between 33-66% (Maksimum Tolarable Dose (MTD) 48-52Gy3) for 4 patients,

less than 33% (MTD 72Gy3) for 25 patients. According to these results the average amount of MPA, mean liver dose and mean tumour dose were found 1793.9±1.46 MBq, 32.86 ±0.19 Gy and 138.26±0.40 Gy. RILD was not observed in any patient. In sub-working group, the relationship between Bilirubin, Albumin, INR (which show presence of liver disease and its degree), liver C with Tc-99m-M and calculated MPAs were found r=0.49, r=0.27, r=0.43, r=0.57 respectively. Conclusions : The min tumour dose was found 120 Gy for positive dose-response relation. If volumetric tumour/liver rate was >66%, dose 30 Gy; if 33-66%, dose escalation 48 Gy; if <33%, dose 72 Gy. These dose limitations did not create RILD. CL measurement with M was concluded that the best method to determine the liver function. Therefore, liver CL rate with Tc-99m-M should be considered in calculation of Y-90 microspheres dosimetry.

P080

Monte Carlo simulations to evaluate dose for possible treatment of brain cancers by boron neutron capture therapy

Z. Jovanovic[1], D. Krstic[1], D. Nikezic[1], **M. Matovic**[2], R. Krstic[3]; [1]University of Kragujevac, Faculty of Science, Kragujevac, SERBIA, [2]Clin Ctr Kragujevac, Kragujevac, SERBIA, [3]KVARK Company, Kragujevac, SERBIA.

Monte Carlo simulations were performed to evaluate dose for possible treatment of cancers by boron neutron capture therapy (BNCT). The computational model of male Oak Ridge National Laboratory (ORNL phantom) was used to simulate tumour in the brain. Calculations have been performed by means of the MCNP5/X code. In this simulation, epithermal neutrons were considered. Boron neutron capture therapy (BNCT) is radio therapeutic modality, based on nuclear capture reaction that occurs when non-radioactive boron (10B) is irradiated with neutrons of the appropriate energy to yield high energy alpha particles and recoiling lithium (7Li) nuclei. Since these particles have path lengths of approximately one cell diameter, their lethality is primarily limited to boron containing cells. The selective boron uptake in the brain metastases comparing to normal tissue makes BNCT a potentially advantageous technique, especially if the whole organ has be treated. In clinical application of BNCT, 10B compounds such as BPA (Boronophenylalanine) and BSH (Sulfhydryl borane) have been widely used as short-range alpha particle-producing agents. The obtained results indicate that the brain cancer could be treated by BNCT under the assumptions of calculations.References1. Brandão F S & Campos PR T. Dosimetric analysis of BNCT - boron neutron capturetherapy - coupled to 252Cf brachytherapy. What is the sensitivity of 90Y SPECT to microscale dose distribution?

C. Oldfield[1], D. Cullen[1], D. Hamilton[2], E. Page[2], A. P. Robinson[1], J. Tipping[2]; [1]University of Manchester, Manchester, UNITED KINGDOM, [2]The Christie NHS foundation trust, Manchester, UNITED KINGDOM.

^{90}Y microsphere treatments provide significant benefits for the therapy of some cancers, e.g. metastatic colorectal cancers. Current administration guidelines make no use of tumour dosimetry despite promising work quantifying tumour dose response for ^{90}Y microsphere therapies [1].The nature of microsphere treatments results in a unique dose distribution due to the discrete nature of the activity localisation. This allows the dose distribution to be specified down to a cellular level, far below the resolution of conventional imaging modalities.Tumour microsphere distributions based on existing data coming from analysis of histological thin slices [2] describing the statistical nature of individual microsphere distributions have been generated. Using these distributions as input to a Monte Carlo model it is possible to calculate doses throughout a tumour at a micrometre scale.This provides the basis of a Monte Carlo simulation study investigating how the microscale distribution of spheres is reflected in macroscale SPECT and PET imaging and subsequent dosimetry.Results showing the theoretical sensitivity of SPECT and PET to the underlying structure of microsphere distribution and its impact on dosimetry will be presented.Dose calculations based on observed microsphere distribution for SIR-sphere and Therasphere treatments are compared.[1] Y H Kao et al, Post-radioembolization yttrium-90 PET/CT - part 2: dose-response and tumor predictive dosimetry for resin microspheres, EJNMMI, 2013[2] A M Campbell et al, Analysis of the distribution of intea-arterial microspheres in human liver following hepatic yttrium-90 microsphere therapy, Phys. A comparison of the utility of F18 Choline and Ga68 PSMA PET/CT in identifying distant disease in high risk prostate cancer patients being considered for radical prostatectomy

S. A. Ali[1], **L. Emmett**[1], J. Wang[1], P. Van Leeuwen[2], D. Stark[1], J. Morigi[1], P. Stricker[2]; [1]St Vincents Public Hospital, Sydney, AUSTRALIA, [2]Garvan Institute for medical research, Sydney, AUSTRALIA.

AIM:To identify the extent of metastatic prostate cancer outside the standard operative or radiotherapy field in high-risk patients undergoing pre-treatment staging with F18 Fluoromethyl-Choline (FMC) and Ga68 PSMA (Prostate specific membrane antigen).MATERIALS:All patients undergoing a pre-operative PET CT (F18 Choline or Ga68 PSMA) were analysed using a prospectively accrued ethics approved database. Gleason score, T staging, PSA and prior imaging results were documented. PSMA and FMC PET/CT plus diagnostic CT scans were undertaken and independently assessed by 2 readers blinded to clinical and imaging results. Management impact information, minor (change in delivery or site of the selected treatment) or major (change of selected treatment) change was documented. Histopathology was documented in all patients.RESULTS:27 patients with FMC and 19 patients with PSMA were included. 36/46 pre- radical prostatectomy and 10/46 pre external beam radiotherapy. Mean Gleason score 8.12 (+/-1.17 SD)(FMC) and 8.53 (+/-1.01 SD)(PSMA). PSA (ng/mL) 20.36 (+/-24.52 SD)(FMC) and 14.81 (+/-18.94 SD)(PSMA). With FMC patients (27), 15 were identified as having disease localized to within the standard operative field (9/15 prostate alone; 6/15 prostate+ local pelvic nodes). 12/27(44%), of whom 4/12 (33%) had bone and 8/12 (%66) distant nodal involvement (above common iliac). With PSMA patients, 13/19 had disease within the standard operative or radiotherapy field (10/13 prostate alone, 3/13 prostate+ pelvic lymph nodes). 6/19 (31%) PSMA had bone lesions with no distant nodes identified (PSMA). Management impact and histopathology results are in process.CONCLUSION:A significant proportion of men with high risk prostate cancer undergoing pre- treatment F18 Choline or Ga68 PSMA demonstrated disease outside of the standard surgical or radiotherapy field (particularly in bone with PSMA) leading to a significant change in management. Ga68 PSMA identified a higher proportion of men with metastatic bone disease than F18 Choline in the high risk pre-operative setting. Further large studies investigating the value of Ga68 PSMA in the high risk preoperative group is warranted.

Targeting VPAC1 for Imaging Prostate Cancer

M. L. Thakur, E. J. Trabulsi, S. Tripathi, S. Kim, P. McCue, R. Birbe, A. Gandhe, P. Kumar, C. Intenzo, L. Gomella; Thomas Jefferson University, Philadelphia, PA, UNITED STATES.

Objectives: Throughout the world, prostate cancer (PC) takes hundreds of thousands of lives each year. Although a large number of minimally invasive and invasive procedures are available for detection of PC, there remains a compelling need for imaging PC and its metastatic and recurrent lesions. As a result, for PET and SPECT imaging of PC, many novel radiopharmaceuticals are being investigated. VPAC1 receptors (combined for vasoactive intestinal and pituitary adenylate cyclase active peptide) are expressed in high density on PC cells at the onset of oncogenesis and play an active role in cell proliferation, differentiation, and cell survival. On stroma, normal cells, and benign masses, only a few VPAC1 receptors are expressed. The goal here was to determine the ability of a VPAC1 receptor-specific biomolecule, ^{64}Cu-TP3805, to image biopsy-proven PC in vivo, and evaluate the findings with pathologic examination.

Methods and Materials: Twenty-five men (age 44-74 yrs, mean 63.4±7.6 yrs) scheduled for radical prostatectomy (Gleason 7) and who signed an IRB approved consent form received 148 mBq (±10%) ^{64}Cu-TP3805 preoperatively. PET images were performed at 30 min. and 2 hrs. post injection. Standardized uptake values (SUVs) were determined, malignant lesions (SUV >1.0) were counted, and data were compared with histological findings. In addition, 9 deparaffinized wholemount pathology slides from 3 benign prostatic hyperplasia (BPH) patients were incubated with ^{64}Cu-TP3805, washed with PBS, dried, and subjected to digital autoradiography (DAR). Slides were then H&E stained, read by pathology, and DAR images were compared with histological findings.

Results: By PET imaging in 25 patients, 127 malignant lesions were identified by histology, all of which were positive by imaging (SUV max range 1.1-8.8). In addition, there were 85 additional lesions with SUV max >1.1. Consistent with histology, DAR was normal for all 9 BPH slides. The pathologic nature of 85 PET lesions is being investigated.

Conclusion: PET imaging with ^{64}Cu-TP3805 accurately visualized all malignant lesions determined by histology. Consistent with histology, DAR examinations of 9 slices from 3 BPH patients showed absence of ^{64}Cu-TP3805 uptake, confirming a lack of VPAC1 receptors on non-malignant, normal cells. It is, therefore, reasonable to consider that the additional 85 PET lesions may not be false positive, but were either missed by histology or may be histologically pre-malignant, such as prostatic intraepithelial neoplasia (PIN), the precursor of PC. ^{64}Cu-TP3805 is worthy of further investigation. **Support**: NIH/NCI R01 CA157372 (MLT)

The incremental value of FDG PET/CT over MDP bone scan in staging of Ewing's group of tumors

r. K. kavindran, **Sr**., s. shah; TMH, mumbai, INDIA.

Introduction: Routine staging for Ewing's group of tumors includes a Tc99m MDP bone csan, CT thorax and a MRI of the local region. FDG PET/CT scans are being increasing used for stgaing various malignancies. Aim: The evaluate the incremental value of F18 FDG PET/CT over Tc99m MDP bone scintigraphy in Ewing's group of tumors. Materials and methods: This is a retrospective analysis of 66 histological proven untreated cases of Ewing's group of tumors. A 99m Tc MDP planar bone scan and FDG PET/CTscan were done within a span of five days. Abreath hold CT chest was done after completion of the PET/CT study. Abnormalities on a MDP bone scan at primary and metastatic sites and the areas of abnormal FDG uptake in the skeletal system on a PET/CT study in all the patients were noted. A comparsion of the skeletal lesions identified by both modalities was done.Additional sites of metastases on a FDG PET/CT were also evaluated. Results: MDP bone scan identified in 4/66(6%) patients while FDG PET/CT identified skeletal disease in 12/66(18%). 50% (6/12) of the leisons identified on PET/CT were purely marrow lesions. FDG PET/CT delineated 22 (33/3) patients with non skeletal metastases (15-lung and 7 nodes),this group consisted of 19 (28.8%) patients who showed only non skeletal metastases while 3 patients had both skeletal and non skeletal metastases. Conclusion: FDG PET/CT in view of its better sensitivity (incremental value of 12%) in delineating skeletal metastses over MDP bone scan and its ability to detect non skeletal metastses (which acconted for 33% in our study) should be considered as a useful modality for stgaing Ewing's group of tumors.

[18F]PR04.MZ for Dopamine Transporter Quantification in Low Density Regions - Complete Evaluation and Dosimetry in Healthy Volunteers

V. Kramer[1], R. Pruzzo[2], E. Hernandez[2], P. Chana[3], C. Juri[4], P. Riss[5], F. Rösch[6], H. Amaral[1]; [1]PositronPharma SA, Santiago de Chile, CHILE, [2]Nuclear Medicine and PET/CT Center FALP, Santiago de Chile, CHILE, [3]Universidad de Santiago de Chile, Santiago de Chile, CHILE, [4]Universidad Catolica, Santiago de Chile, CHILE, [5]University of Oslo, Oslo, NORWAY, [6]Johannes Gutenberg-Universität Mainz, Mainz, GERMANY.

Objectives: Deterioration of dopaminergic cells in the Substantia Nigra and subsequent dopaminergic deficiency in striatal regions is the main hallmark of Parkinson's Disease. Quantification of the cellbodies in this area remains difficult due to low dopamine transporter concentrations and partial volume effects. 18F-PR04.MZ is a new, high affinity radioligand for dopamine transporters, currently under investigation at our center. Aim of this study was to perform a complete evaluation and dosimetry study with 18F-PR04.MZ in healthy volunteers.Methods: 5 healthy volunteers (mean age 23 ± 2 a) underwent a dynamic PET scan (Siemens mCT) for a duration of 180 min after bolus injection of 203 ± 21 MBq (mean ± SD) [18F]PR04.MZ. PET scans were co-registrated to T1 weighted MRI scans and normalized to a brain template. Blood input function was recorded via automated online blood sampling (Twilite/Swisstrace) and plasma and parent fraction was determined by a HPLC method. Distribution volumes and binding potentials were determined by different invasive and non-invasive methods. 5 healthy volunteer underwent serial whole body PET scans for 2h to determine biodistribution and estimate internal radiation dose.Results: [18F]PR04.MZ showed a relatively fast kinetic and very high specific uptake in DAT containing brain regions. Peak uptake in putamen was reached after 25 minutes followed by slow washout. Distribution volumes were determined using 2TCM and were well correlated with non-invasive methods like SRTM. Stepwise reduction of scan duration from 180 to 90 min showed stable estimates for most binding potentials. The biodistribution study revealed urinary bladder and gastrointestinal system as main excreting organs and bone uptake was observed due to defluorination. Results from the dosimetry study are currently under evaluation but preliminary estimates showed no critical levels of radiation burden.Conclusions: [18F]PR04.MZ is a promising tool for precise quantification of striatal and extrastriatal dopamine transporters and its kinetic provides suitable and stable estimates after only 90 min of scan duration. Studies including REM sleep disorder patients and early PD patients are currently ongoing to estimate DAT density in different brain regions in early phases of PD.

P086

The potential impact of congestive heart failure (CHF) on FDG PET/CT studies

M. Ahmed[1], R. Muzaffar[1], **M. M. Osman**[1,2]; [1]Saint Louis University, Saint Louis, MO, UNITED STATES, [2]Saint Louis VA, Saint Louis, MO, UNITED STATES.

Objective:Congestive heart failure (CHF) is not uncommon among cancer patients undergoing FDG PET/CT. When present, CHF may induce reactive mediastinal adenopathy with or without cardiac cirrhosis (congestive hepatopathy). Therefore, CHF may be a source of false positive mediastinal nodes and

affect the standard uptake value (SUV) of the liver, a frequently used internal reference point in FDG PET/CT scans. We aimed to assess if CHF results into reactive mediastinal adenopathy and or affect liver SUV.Method:A retrospective study was conducted comprising of 82 patients with known CHF who had FDG PET/CT examination. Patients with malignant mediastianal lymphadenopathy, no measurable lymph nodes or completely calcified nodes were excluded resulting in a total of 31 CHF patients. They were compared with 35 age and gender matched non-CHF controls. A log was created to record the number of measurable mediastinal lymph nodes (LN), short axis size measurements, SUV max and mean Hounsfield Units (HU) of the nodes from PET/CT scans. A region of interest (ROI) was also drawn over the posterior right hepatic lobe to measure the SUV max.Results:A total of 66 cases were reviewed (31 female, 35 male, mean age of CHF group 69, mean age range of non-CHF group 70, total age range 57-90 yrs.). Mean values of the CHF vs non-CHF group are as follows:HU (mean): CHF 46.5 +/- 25.40 vs Non-CHF 47.79 +/- 24.94; p-value 0.77SUV max: CHF 1.96 +/- 0.94 vs Non-CHF 1.95 +/- 0.64; p-value 0.94LN short axis(mm): CHF 8.87 +/- 3.95 vs Non-CHF 7.67 +/- 2.66; p-value 0.04Liver SUVmax: CHF 2.79 +/- 0.62 vs Non-CHF 3.13 +/- 0.66; p-value 0.002A two tailed test of significance demonstrated a statistically significant difference in the size of LN for the 2 groups but was still below 10 mm in diameter, which is considered a cut-off in size for assessing lymphadenopathy. However, the t-test for Liver SUV was also significant with a p-value of 0.002.Conclusion:We conclude that the presence of CHF does not result in statistically significant reactive mediastinal adenopathy; however, it does result into lower liver SUV compared to age and gender matched controls without CHF. Therefore, the mediastinum may serve as a better reference point than the liver in patients with CHF. Further studies are needed to elucidate the CHF-induced hepatopathology and potential impact on FDG PET/CT exams.

P087

The Effect of Pulmonary Hypertension on Standardized Uptake Values of the Liver and Pulmonary artery in FDG PET/CT Imaging

M. Mikhayel[1], N. Parkar[1], R. Muzaffar[1], P. Kelly[1], **M. M. Osman**[1,2]; [1]Saint Louis University, Saint Louis, MO, UNITED STATES, [2]Saint Louis VA, Saint Louis, MO, UNITED STATES.

Objective: Pulmonary hypertension (PH) is not uncommon among cancer patients who routinely undergo FDG PET/CT for evaluation and follow up of their malignancy. Other risk factors for the development of PH include drugs and toxins, including chemotherapeutic drugs, as well as underlying portal hypertension. Liver and mediastinal blood pool are being used as internal reference points in FDG PET/CT examinations. The objective of this study was to evaluate potential impact of PH on standardized uptake values (SUV) within the liver and mediastinal blood pool in cancer patients undergoing PET/CT.
